RE: Newmont Brucejack – 4950 tpd Joint M-243 / PE-107835 Amendments Application

To whom it may concern,

Please find attached the following documents in support of the joint application to amend *Mines Act* Permit M-243 and *Environmental Management Act* Effluent Permit 107835 (PE-107835) to increase the Brucejack Mine average ore production rate from 3800 tpd to 4950 tpd:

1. Environmental Protection Notice
2. Brucejack Mine 4950 tpd Joint M-243 / PE-107835 Amendments Application (4950 tpd Joint Application)

The 4950 tpd Joint Application is an application by Pretium Resources Inc. (Pretium), now operating under Newmont Corporation (Newmont), to increase the Brucejack Mine average ore production rate to 1,806,750 tonnes per year (tpy) (4950 tpd) from the current authorized average rate of 1,387,000 tpy (3800 tpd). There is no proposed change to the Brucejack Mine Environmental Assessment Certificate M15-01 life-of-mine ore limit of 18.5 Mt and no change to the *Mines Act* Permit M-243 WRTSF waste rock deposition limit of 11.9 Mt. The proposed increased ore production rate would reduce the mine life by 3 years from current, with mining projected to cease at the end of 2029 rather than 2032.

Please do not hesitate to contact the undersigned if you require further information and/or clarification on this application. Communications regarding the 4950 tpd Joint Amendments Application should be directed to:

ENVIRONMENTAL PROTECTION NOTICE

Application for a Permit Amendment Under the Provisions of the *Environmental Management Act*

We, Pretium Resources Inc. (Pretium), operating under Newmont Corporation, PO Box 10, 2965 Tatlow Road, Smithers, BC, V0J 2N0, have submitted an application to the Director to amend the *Environmental Management Act* (EMA) effluent Permit PE-107835, issued August 31, 2015 (last amended August 21, 2023), which authorizes discharge of effluent from the Brucejack Mine. The amendment application requests changes to the permit to support a proposed increase in the average ore production rate from 3800 tonnes per day (tpd) to 4950 tpd.

The land upon which the facility is situated, and the discharge occurs, is Mining Lease Tenure Number 1038598, located at 56.47N and 130.19W, approximately 65 km north-northwest of Stewart BC within the Regional District of Kitimat Stikine.

The amendment application requests under existing PE-107835 Condition 1.1.1 that the characteristics of the mine effluent being discharged at the Waste Rock and Tailings Storage Facility (WRTSF) outlet (BJ 3.10) be changed to:

Parameter or Contaminant Name	EXISTING Authorized Limit and Units	AMENDMENT REQUESTED Limit and Units
Total Arsenic	10 µg/L	26 µg/L
Nitrate	11.5 mg/L as N	20 mg/L as N
Dissolved Copper	-	0.9 µg/L
Total Selenium	-	6.2 µg/L

The amendment application requests an amendment to permit Condition 1.5.3 to increase the number of authorized Filterbox C75 domestic wastewater treatment units from three to four.

A copy of the permit application, including supporting documentation, is available electronically at https://operations.newmont.com/north-america/brucejack-canada in the Reports and Documents section. Any person who may be adversely affected by the proposed amendment and wishes to provide relevant information may, within 30 days after the last date of posting, publishing, service or display, send written comments via post or email to the applicant, with a copy to Rosanna Breiddal, Senior Project Lead, Major Mines Office, Ministry of Energy, Mines and Low Carbon Innovation, PO Box 9320 Stn Prov Govt, Victoria, BC, V8W 9N3, (Rosanna.Breidall@gov.bc.ca). The identity of any respondents and the contents of anything submitted in relation to this application will become part of the public record.

Dated this 4 day of January 2024.

November 2023

EXECUTIVE SUMMARY

Introduction

This report is the 4950 tpd Joint M-243/PE-107835 Amendments Application (4950 tpd Joint Application) by Pretium Resources Inc. (Pretium), a member of the Newcrest Group of companies, to increase the Brucejack Mine average ore production rate from the currently M-243 authorized average of 1.387 Mtpa to 1.807 Mtpa (equivalent average 3800 tpd to 4950 tpd). The report provides the technical and other information required by the approved Joint Information Requirements (JIRT) for this application.

Specifically, Pretium is applying to amend Brucejack Mine *Mines Act* Permit M-243 and *Environmental Management Act* Effluent Permit 107835 as required to authorize the production rate increase. Pretium's overall approach to the proposed production rate increase is to minimize changes aside from increasing the ore production rate. The increased production rate will not result in any changes to the Environmental Assessment (EA) Certificate M15-01 life-of-mine (LOM) ore limit (18.5 Mt) or Certified Project Description (CPD), or the M-243 current Waste Rock and Tailings Storage Facility (WRTSF) waste rock deposition limit (7.8 Mt).

Brucejack Mine is an underground gold mine located in northwest British Columbia, approximately 950 km northwest of Vancouver and 65 km north-northwest of Stewart. Ground access is via the 73 km Brucejack Access Road (BJAR) which originates at Hwy 37 km 215. The mine's mining, processing and other primary infrastructure is located at an elevation of approximately 1365 masl at the headwaters of Brucejack Creek, a westerly draining non-fish bearing tributary of the Unuk River via Sulphurets Creek. Construction of the mine began in September 2015, with commercial production commencing in July 2017. The Brucejack Mine, the BJAR and the Brucejack transmission line lie within the asserted traditional territory of the Tsetsaut Skii km Lax Ha, and portions lie within the Nass Area of the Nisga'a Nation as defined in the Nisga'a Final Agreement, and the asserted territory of the Tahltan Nation.

This 4950 tpd Joint Application has been prepared with reference to the Joint Application Information Requirements (MEMPR & ENV 2019), and includes the following chapters:

1. Introduction and Project Overview
2. Baseline
3. Mine Plan
4. Reclamation and Closure
5. Modelling, Mitigation and Discharges
6. Environmental Assessment Predictions
7. Environmental Monitoring
8. Health and Safety
9. Management Plans

Mine Plan Update

The 4950 tpd mine plan presented in this 4950 tpd Joint Application has been updated based on the mine plan presented in the 2019 National Instrument 43-101 Technical Report dated March 9th, 2020 (Tetra Tech 2020). The production rate increase from 3800 tpd to 4950 tpd would result in a shortened mine life from the 16 years spanning 2017 through 2032 presented in the 2020 mine plan, to 13 years spanning 2017 through 2029.

Established mine site facilities within the mining leases include:

- Four underground vent air raises;
- VOK and WZ underground mine portals;
- WZ pad, within which surface support infrastructure for the underground mine is located. This includes the old heavy shop, staging areas for waste rock, offices, covered storage, propane storage for mine air heater, and fuel storage and dispensing stations;
- Diesel power station (DPS) pad, including diesel generators and fuel storage serving as a back-up electrical generation facility;
- Mill building housing ore processing equipment, smelting furnace, WTP, paste backfill plant, assay laboratory, core processing area and related facilities;
- Lower and upper camps with kitchen, recreation, laundry, mine and mill dry facilities, medical clinic, fire hall, administration/offices, potable water well distribution and treatment system, STP, and solid waste management systems;
- Surface heavy duty shop to service surface vehicles and mobile equipment;
- Cement binder storage silo for pasting operations;
- Avalanche cap and powder magazines;
- Warehouse, coverall storage and equipment laydown areas;
- Heli-pad;
- Solid waste sorting and handling facilities, incinerator, waste oil burners, and burn pits;
- Contact and non-contact water management facilities, including mine dewatering, freshwater diversion channels, surface contact water collection system and a contact water storage pond (CWP);
- Overburden stockpile;
- The WRTSF containing five subaqueous tailings discharge pipelines, a treated WTP/STP effluent discharge pipeline, an emergency discharge pipeline from the CWP, and the WRD platform and associated temporary waste rock stockpile (WP1) that facilitates subaqueous waste rock deposition;
- A low-level weir (LLW) at the WRTSF outlet (site BJ 3.10) housing flow monitoring instrumentation and water reclaim equipment. The LLW facilitates continuous from the WRTSF to Brucejack Creek and houses a reclaim water pumping system that provides fresh water for to the mill;

- NPAG quarry (km 72 NPAG quarry) that provides NPAG material for surface and underground mine development and road maintenance;
- Site roads to connect mine area facilities, including the BJAR section between the km 72 NPAG quarry and the mine site; and
- Communication, monitoring, and control systems, including wireless local area network receivers, underground fiber optic network, radio base stations, programmable logic controllers, and video cameras.

The following infrastructure upgrades and equipment changes have been identified to facilitate the production increase from 3800 tpd to 4950 tpd:

- Increasing the haul truck fleet size from eight to 11 (at minimum) 50 t BEVs and addition of an electric load-haul-dump (LHD) vehicle;
- Additional Knelson concentrator within the mill, and equipment upgrades to the gravity and floatation circuits;
- A fourth C75 domestic wastewater treatment unit;
- Increasing the mine's power supply delivered by the existing 138 kV and 69 kV lines to 35 MVA, for which both lines are adequately rated; and
- Additional underground emulsion bay.

A second waste rock dump (East WRD), temporary surface waste rock stockpile(s) (WP2) and supporting haul road are being evaluated as a potential contingency management option to be developed east of the WRTSF and will be addressed via separate applications. These proposed upgrades to the existing waste rock management infrastructure are intended to provide contingency to the mine's waste rock management strategy, irrespective of the production rate increase.

Similarly, a fifth vent raise (VR5) and four new tailings discharge lines to the WRTSF are being considered for installation between 2023 and 2026, regardless of production rate. The new tailings lines are intended to replace existing and future tailings lines through LOM.

The Brucejack Mine produces gold and silver from the VOK and WZ deposits. The vertical and horizontal extents of the underground mine development for the 4950 tpd Joint Application mine plan remain similar to those presented in the 3800 tpd Amendment Application as per Permits M-243 and PE-107835 (Pretium 2018b) and the 2020 Mine Plan and Reclamation Program Update (Pretium 2020b). Mine plan changes in the 4950 tpd Joint Application compared to these previous submissions include updates to a subsection of the VOK called the North Block, and additional underground exploration development to the east, west and south.

Small portions of the updated exploration development extend beyond the current M-243 Permitted Mine Area (PMA) extents. In September 2022, Pretium submitted an M-243 permit amendment application to extend the mine's current PMA to the existing mining lease boundaries (M-243 Amendment #9). If approved, exploration development currently outside of the PMA will be inside it.

All waste rock at the mine is managed as PAG and is either deposited subaqueously within the WRTSF at the mine's WRD, or backfilled in mined out areas in the underground mine below the predicted closure flooding elevation. Mine tailings are co-mingled with sludge from the mine's WTP and deposited subaqueously in the WRTSF. Total Life-of-Mine (LOM) waste rock deposition to the

WRTSF remains within the 7.8 Mt currently authorized under M-243, and total tailings deposition to the WRTSF remains below the authorized 11.9 Mt.

The underground mine has been designed to extract ore through a combination of transverse long hole open stoping (LHOS) and longitudinal LHOS in a traditional primary/secondary sequence. Primary stopes are backfilled with cemented paste tailings and secondary stopes are backfilled with cemented paste tailings or waste rock. The mine utilizes a combination of conventional bulk sulphide flotation and gravity concentration to produce gold-silver floatation concentrate and doré from the on-site smelter. Both products are transported offsite for additional processing and refinement.

The increased mining rate from 3800 tpd to 4950 tpd will be sustained by expanding the battery electric vehicle (BEV) fleet and increased rates of drilling and development. No changes from the mining methods presented in the 2020 Mine Plan and Reclamation Program Update (Pretium 2020b) are required to achieve the production increase. Unrelated to the proposed production rate increase, Pretium is continuing to expand the Brucejack Mine battery electric vehicle fleet.

Reclamation Program Update

The Reclamation and Closure Plan addresses mine infrastructure components and site disturbance authorized under M-243, including mine development within the PMA portion of the mining leases and the portion of the mine's transmission line extending south from the mining leases to Pretium's Mineral Claim #1026976. Permit M-243 authorizes the northernmost 19.5 km of the transmission line; the 37.5 km segment located south of that is authorized under Statutory ROW #6408729.

There is no new surface disturbance associated with the proposed production rate increase, and therefore the Reclamation and Closure Plan does not include changes specific to the 4950 tpd Joint Application with the exception of infrastructure timing shown on the reclamation progression figures (e.g. WRTSF related mine wastes extents and mine closure in 2029). The Reclamation and Closure Plan has however, been updated to reflect surface infrastructure changes since the 2020 update (Pretium, 2020b) and for planned or proposed changes that are required for the existing mine operation irrespective of the proposed production rate increase.

Brucejack Mine surface disturbance areas are limited in extent due primarily to it being an underground mine. The M-243 approved PMA is 659.3 ha, with approximately 195 ha covering a 100 m corridor along the northernmost 19.5 km of the transmission line, and the remaining approximately 464 ha being located within the mining leases. Actual disturbance at end of 2022 was calculated at 278 ha; however, the historical exploration buffer areas are minimally disturbed and have been partially reclaimed. The terrestrial disturbance area total for the mine site primary infrastructure area is 55 ha which includes mine site infrastructure and related disturbance areas.

The end land use objective remains the same as required by M-243: wildlife habitat, particularly matrix habitat for mountain goat, grizzly bear and hoary marmot on the mine site and high elevation sections of the transmission line, and moose and grizzly bear habitat at lower elevations of the transmission line. The mine and its operations have been planned and designed to limit the terrestrial development footprint and to prevent significant adverse effects on the downstream aquatic receiving environment, including both water quality and aquatic biota. The general approach to reclamation and closure planning continues to be creation of post-mine topography and conditions that will achieve the matrix habitat end land use and support passive natural revegetation to the extent feasible. The post-closure

mine site will have low vegetation cover, consistent with its pre-mine condition and with surrounding areas, as most of the adjacent landscape is comprised of unvegetated bedrock exposures.

Mine closure activities are planned for implementation in a sequential manner such that infrastructure needed to the end of mine closure remains in place and all other reclamation activities occur in a logical progression. Underground mine reclamation, including removal of underground mobile equipment and completion of other pre-flooding preparatory measures, and flooding will begin immediately following closure. Removal of surface equipment, buildings and infrastructure not required for water treatment and ongoing reclamation activities will occur during the first summer season of the closure phase. Surface reclamation will then be conducted as described below, including recontouring to prevent barriers or hazards to wildlife, establishment of stable post-closure surface drainage, and decompaction as appropriate.

Mine flooding is estimated to be complete within seven months based on accelerated flooding accomplished by water withdrawal from the WRTSF. The withdrawal rate will be to the current licensed rate during the winter low flow period, and at accelerated rates during the freshet high flow period. Water treatment of the underground mine pool will occur throughout the active flooding period, and is predicted will occur for an additional eight months after flooding is completed (total 15 months). Watertight plugs will be installed in the WZ and VOK portals, and in the raise planned north of Brucejack Creek, during the first year of the closure phase to allow underground mine flooding to its ultimate flooding elevation. Remaining surface reclamation will be completed once active water treatment is no longer required, along with removal of remaining surface infrastructure and equipment, including the water treatment plant and transmission line.

Based on the 4950 tpd mine plan (refer to Chapter 3), the remaining mine life is approximately 7 years, with operations ceasing at the end of 2029. This will be followed by a closure phase estimated at three years that includes two years of closure and reclamation within the M-243 area, and a third year of reclaiming off-site mine related infrastructure (i.e. the BJAR and adjacent infrastructure below Knipple Glacier and extending to the Highway 37 intersection, and the Statutory ROW authorized portion of the transmission line). A post-closure monitoring period of ten years is planned for the M-243 area following mine closure. Post-closure monitoring and reporting will include surface water quality, sediment quality, aquatic resources, groundwater quality and levels, structural integrity of portals and raise watertight plugs, geotechnical, and reclamation success.

Modelling, Mitigation and Discharges

The existing groundwater model, water balance model, and water quality model for the 3800 tpd production rate were updated to include the changes to the mine plan associated with the proposed increase to a daily average ore production rate of 4950 tpd. Updates to these models also included refinement of model inputs using recent monitoring data and test results. Results of the water quality model were screened to identify parameters of concern. A best achievable technology (BAT) assessment was carried out to evaluate treatment options for the parameters of concern, associated costs, and feasibility of implementation. An effects assessment was conducted to assess potential risk to aquatic life in the receiving environment from the modelled water quality, without the implementation of the technology identified by the BAT assessment. Considering the results of the BAT assessment and the effects assessment, Pretium is proposing to amend PE-107835 to increase current discharge limits for nitrate and total arsenic (T-As), and to request the addition of discharge limits for dissolved copper (D-Cu) and total selenium (T-Se). The proposed discharge limits were assessed to have low risk to aquatic life in the receiving environment and to avoid adverse effects of

treatment at the WRTSF outlet which include high energy demand, generation of by-products, and high costs.

MODELLING

The updated 4590 tpd groundwater model predicts increased inflow rates over LOM, but less overall groundwater extraction as compared to the 3800 tpd model. The increased flows to the underground mine will be managed effectively by the mine's current water collection and treatment system. Predicted changes in baseflow reporting to Brucejack Creek for the 4950 tpd production rate are similar to those predicted for the 3800 tpd production rate. Contact groundwater flow rates to Brucejack Creek at closure are predicted to be higher than those predicted for the 3800 tpd mine plan on account of the slightly deeper and broader mine development.

The updated water balance model incorporates anticipated changes to mine site and receiving stream flows based on the increased mining rate for a Base Case scenario, representing average climate conditions. This model forms the basis for the updated water quality predictions. Additional water balance model runs were carried out to assess the model's sensitivity to variable tailings solids content, variable climate conditions, and climate change.

The water quality model was revised to account for the increased ore production rate and the associated mine plan. Revisions to the model include the incorporation of revised flows from the updated groundwater model and water balance model, changes to the mine waste schedules, and updates to geochemical source terms based on new data and trends observed in the monitoring data sets. The water quality model incorporates loadings from mine sources and background flows to generate Base Case and Upper Case water quality predictions at two sites in Brucejack Creek: BJ 3.10, the mine's regulated discharge point, located at the outlet to the WRTSF; and BJ 2.62, a downstream monitoring location in Brucejack Creek. The Base Case is considered to represent the expected water quality and the Upper Case incorporates the combined effects of Upper Case geochemical source terms for all mine-related inputs.

The water quality model results were evaluated to identify parameters that are likely to have concentrations at BJ 3.10 or BJ 2.62 that exceed current discharge limits, or concentrations that are greater than BC water quality guidelines for protection of aquatic life for parameters that don't have discharge limits, during the life of mine. This process identified nitrate, nitrite (during closure only), arsenic, copper, and selenium as parameters of concern (POCs) that will require additional mitigation to meet current conditions in PE-107835 or revisions to discharge limits in PE-107835.

The water quality model report evaluated the potential for the modelled water quality to cause adverse effects to aquatic life in the receiving environment. Brucejack Creek provides habitat for benthic invertebrates and periphyton, but is not fish habitat. The closest fish-bearing waters are more than 20 km downstream of Brucejack Creek, below a barrier to fish migration near the mouth of the Sulphurets River. The effects assessment concluded that there is low risk to aquatic life in Brucejack Creek from the modelled water quality during all mine phases, except for the Upper Case model results for selenium during closure, which was categorized as having a moderate risk of causing adverse effects.

MITIGATION

Source control is a primary method that is used to maintain acceptable effluent quality at the outlet of the WRTSF (BJ 3.10). Source control procedures developed for the mine are described in environmental management plans, including the ML/ARD Management Plan, Nitrogen Management Plan, Chromium Management Plan, the WRTSF OMS Manual, and the Water Management Plan OMS Manual. Treatment of mine contact water by the water treatment plant (WTP), and treatment of sewage by the sewage treatment plants (STPs), prior to discharge to the WRTSF, are also primary mitigation methods. Monitoring of the various sources of contaminant loadings to the WRTSF, and monitoring of WRTSF effluent at BJ 3.10, show that the source control measures implemented have been effective in maintaining acceptable discharge quality. It is anticipated that these measures will continue to be effective for a production rate of 4950 tpd.

A best achievable technology (BAT) assessment was conducted to evaluate options for water treatment at the outlet of the WRTSF to meet current discharge limits and applicable water quality guidelines at BJ 3.10 during the operations phase, under the proposed increased production rate scenario. It was determined that treatment at the WRTSF outlet would be required to meet discharge criteria (effluent limits or water quality guidelines) for POCs identified by the water quality model because a significant proportion of total loadings of these POCs occurs in the WRTSF, downstream of existing mitigations. The BAT assessment was conducted in accordance with the step-by-step process described in the ENV guidance document titled *Best Achievable Technology Assessment to Inform Waste Discharge Standards Handout*, published in October 2021. Treatment technologies for POCs were identified and evaluated for feasibility, reliability, control-effectiveness, and cost-effectiveness.

The BAT assessment concluded that the low effluent limits for T-Se and D-Cu require the use of reverse osmosis (RO) technology. Reverse osmosis is a robust treatment solution for NO_3 and T-As as well. Therefore, RO is considered best achievable technology to meet the current discharge criteria for all POCs during the operations phase, based on the flows and water quality predicted for WRTSF discharge under the proposed increased production scenario. Based on the selected BAT (i.e., an RO-based system), treatment of the high flow rates expected at the WRTSF outlet would require an impractically large footprint and high energy demand. Further, the RO process generates a waste stream concentrated in contaminants which will require management and additional treatment, resulting in additional operational complexity and cost. The estimated capital and operating costs of a WRTSF treatment system (with the capacity to treat approximately 50% of predicted peak flows) are approximately $73,000,000 CAD and $27,500,000 CAD/year, respectively. Based on these negative aspects of constructing and operating a RO treatment plant at the outlet of the WRTSF, coupled with the conclusions of the effects assessment that there is low risk to aquatic life in the receiving environment from the proposed limits (refer to next section), treatment of the WRTSF is considered impractical and uneconomical. In lieu of treatment at the WRTSF outlet, new or increased BJ 3.10 discharge limits for POCs are proposed.

PROPOSED DISCHARGE LIMITS

PE-107835 specifies conditions required for effluent discharged from the WRTSF to Brucejack Creek, including the maximum concentration of several parameters. Parameters without specified discharge limits are expected to meet BC water quality guidelines for the protection of aquatic life, because WRTSF discharge is the headwaters of Brucejack Creek which does not allow for an initial dilution zone. The 4950 tpd water quality model results indicate that concentrations of nitrate and T-As in

Brucejack Creek will likely exceed current discharge limits, and concentrations of D-Cu and T-Se will likely increase to values greater than BC long-term water quality guidelines. Pretium is applying to increase the discharge limit for nitrate to 20 mg-N/L and to increase the discharge limit for T-As to 26 µg/L. Pretium is also applying to add a discharge limits to PE-107835 of 0.9 µg/L for D-Cu and of 6.2 µg/L for T-Se. These discharge concentrations are set at the maximum Upper Case modelled concentration at BJ 3.10 during operations. The decision to apply for these discharge limits considers the conclusions of the effects assessment that there is low risk to aquatic life in the receiving environment from the proposed limits, and negative effects of constructing and operating an RO treatment plant at the WRTSF outlet which include the generation of a waste stream that requires additional treatment, the high energy requirements for the plant, and the high expenses required to build and operate an RO plant at the WRTSF outlet.

Environmental Monitoring

Pretium implements an extensive environmental monitoring program at the Brucejack Mine site and its vicinity, in accordance with the monitoring requirements of the mine's authorizations and its management plans. Groundwater is monitored at 31 groundwater wells, according to conditions in PE-107835 which require measurement of groundwater levels at all wells and groundwater quality at 28 of the wells. Inflows to the underground mine are computed daily using the underground dewatering rates measured from water pumped to the water treatment plant. Mine water flows are monitored at the WTP, STPs, the discharge from the contact water pond, and tailings discharge to the WRTSF. Stream flows are continuously monitored at two sites in Brucejack Creek (BJ 3.10 and BJ 1.74) and in upper Sulphurets Creek just downstream of Sulphurets Lake (SC-1).

Surface water quality is measured at locations within the mine site (WTP influent and effluent, tailings supernatant, and STP effluent), in the receiving environment (three locations on Brucejack Creek and one location in upper Sulphurets Creek), in the Camp Creek tributary to Brucejack Creek, and at a reference stream 20 km northwest of the WRTSF at the frequencies required by PE-107835. Water quality samples are analyzed for general parameters, major ions and nutrients, total and dissolved metals, and total organic carbon.

Monitoring programs have also been developed to assess the impact of disturbances and waste products associated with the various mine facilities including the NPAG Quarry, the mine site, the underground mine, the process plant and the WTP. Monitoring programs include collection of solid samples (waste rock, quarry rock, tailings, WTP sludge), as well as leachate (NPAG Quarry, mine site runoff, paste backfill drainage) and water quality (tailings supernatant, underground mine sumps and seeps) samples at frequencies prescribed the mine's ML/ARD management plan. Various kinetic test programs have also been developed to evaluate the long-term behaviour of mine site materials and to inform the geochemical source terms applied to the mine's water quality model.

Effluent quality from the WRTSF is measured weekly at BJ 3.10. Toxicity testing of BJ 3.10 water is conducted using a *Daphnia magna* acute lethality test, an algae growth inhibition test, and a survival and growth test of the freshwater invertebrate *Chironomus dilutus*. Toxicity testing is also conducted to meet the requirements of the federal Metal and Diamond Mine Effluent Regulations, which require a rainbow trout acute lethality test and a *Ceriodaphnia dubia* reproduction and survival test, in addition to the *Daphnia magna* acute lethality test.

Sediment quality, periphyton community characteristics, and benthic invertebrate community characteristics are sampled in Brucejack Creek, upper Sulphurets Creek, and reference site L3-OF according to the requirements of PE-107835.

No additional environmental monitoring is proposed for the 4950 tpd mine plan, since the increase to the ore production rate will not produce additional surface disturbance, and the existing monitoring programs meet environmental monitoring needs.

Health & Safety

Existing Brucejack Mine Health and Safety related management plans and associated procedures will remain in effect with the proposed production rate increase; no changes are necessary specific to the change in production rate.

Management Plans

Established management plans will continue to be applied throughout the operations and closure phases. Current versions of all 21 component management plans required under Schedule B of EAC M15-01 and 10 additional management plans required through other BC provincial authorizations (mainly permit M-243, PE-107835 and PA-107025) which comprise the Brucejack Mine Environmental Management System (EMS) are included in this application. Consistent with previous applications and reviews, any required updates to management plans for the proposed production increase will be completed post-review to incorporate changes resulting from the review. Pretium currently anticipates that the following management plans and OMS manuals may require revisions following the 4950 tpd Joint Application review process: Metal Leaching/Acid Rock Drainage (ML/ARD) Management Plan, Nitrogen Management Plan, Subaqueous Waste Rock and Tailings Deposition Management OMS Manual, Closure and Underground Water Quality Adaptive Management Plan, Backfill Management Plan, and Ventilation Management Plan.

1. INTRODUCTION AND PROJECT OVERVIEW

1.1 Application Background

This document is the 4950 tpd Joint *M-243* / *PE-107835* Amendments Application (4950 tpd Joint Application) by Pretium Resources Inc. (Pretium), a member of the Newcrest Group of companies, to increase the Brucejack Mine average daily ore production rate from the currently authorized average 3800 tpd to 4950 tpd (1.387 Mtpa to 1.807 Mtpa).

Following Newcrest Mining Limited's (Newcrest's) acquisition of Pretium in Q1 2022, Brucejack Mine operations were reviewed to identify short and long-term opportunities to optimize the mine's operations and to increase its longevity and sustainability. The following objectives were identified from this review process:

1. Short-term objective: Increase the mine's ore production rate in the short-term based on minimal changes beyond the production rate. This includes no changes to the:

- Brucejack Mine Environmental Assessment (EA) Certificate M15-01 life-of-mine (LOM) ore limit of 18.5 Mt
- *Mines Act* (*MA*) Permit M-243 current Waste Rock and Tailings Storage Facility (WRTSF) waste rock deposition limit of 11.9 Mt; and

2. Long-term objective: Initiate work that will enable mine life extension in the longer term.

This 4950 tpd Joint Application is to request authorizations specific to the shorter-term objective identified above (bullet #1). As above, Pretium's overall approach to the 4950 tpd Joint Application is to minimize changes aside from increasing the ore production rate.

Separate from this application, Pretium is initiating work to address the longer-term objective of increasing mine life (bullet #2). This requires additional exploration to confirm more ore reserves, additional mine planning and design, and other mining and environmental related studies. This will be followed by additional applications to amend Brucejack Mine permits and other authorizations as appropriate.

1.2 Application Structure

The following outlines the application structure for the 4950 tpd Joint Application.

1. **Introduction and Project Overview** – This chapter introduces the 4950 tpd Joint Application, Pretium, and the Brucejack Mine, and presents an overview of proposed production rate increase related mine/operations changes.
2. **Baseline Information** – Chapter 2 provides high level descriptions of baseline environmental conditions; references baseline information presented in the 2014 Application for an Environmental Assessment Certificate / Environmental Impact Statement (EAC/EIS Application) (Pretium 2014) and 2015 Applications for *MA and Environmental Management Act (EMA)* Permits Application (*MA/EMA* Permits Application) (Pretium 2015); and references locations in the 4950 tpd Joint Application where currently available monitoring and other information (i.e. the pre-4950 'condition') are presented.

3. **Mine Plan** – Chapter 3 describes the 4950 tpd mine plan, including underground mine development; changes to underground and surface infrastructure including the mill and WRTSF; mine waste handling and deposition in the underground mine and the WRTSF; and underground mine and WRTSF geotechnical considerations.
4. **Reclamation and Closure Plan** – Chapter 4 summarizes the content of the Reclamation and Closure Plan, including updates specific to the proposed 4950 tpd production rate increase and to reflect minor changes since the 2020 Mine Plan and Reclamation Program update submission in July 2020 (2020 Update: Pretium, 2020b). The Reclamation and Closure Plan presented as a chapter in the 2020 Update has been revised to a stand-alone management plan that is appended to this application.
5. **Modelling, Mitigation and Discharges** – Chapter 5 summarizes results of groundwater, water balance, and water quality modeling that has been updated for the 4950 tpd Joint Application, and characterizes the modeled discharge concentrations. Modeling details are presented in modeling report appendices using the same approach as the 2020 Update (Pretium, 2020b).
6. **Environmental Assessment Predictions** – Chapter 6 provides an assessment of potential residual effects to aquatic life from predicted changes to water quantity or quality associated with increase to an average 4950 tpd production rate.
7. **Environmental Monitoring** – Chapter 7 describes existing monitoring plans, which are regularly updated. Results of monitoring programs, including changes to monitoring plans that were made each year, are reported in the Brucejack Mine Annual Report for *Mines Act* Permit M-243 and *Environmental Management Act* Permits PE-107835 and PA-107025 *(MA/EMA* Annual Report).
8. **Health and Safety** – Chapter 8 describes that existing Health and Safety related management plans and associated procedures will remain in effect with the proposed production rate increase; no changes are necessary specific to the change in production rate. This chapter also provides an overview of underground mine emergency preparedness.
9. **Management Plans** – This section describes proposed changes to management plans associated with increase to an average 4950 tpd ore production rate.

Refer to Appendix 1-2 for the final Joint Information Requirements Table (JIRT) which serves as the table of concordance and specifies where information requested during the JIRT review period can be located within the 4950 tpd Joint Application. The application is intended to provide the information requested in the final JIRT (Appendix 1-2) and the Application Instruction Document (Appendix 1-3).

1.3 Proponent Information

Newcrest Mining Limited is a publicly traded company, with common shares trading on Australian Securities Exchange (ASX), Toronto Stock Exchange (TSC) and the Papua New Guinea (PNG) Exchange Markets (PNGX). Newcrest's head office is located in Melbourne, Australia. Following its acquisition of Pretium Resources Inc. in Q1 2022, Newcrest established a regional office in Vancouver British Columbia (BC). Newcrest also has a northwest BC office and warehouse located in Smithers BC. Newcrest owns operating mines in Australia, Canada and Papua New Guinea. Newcrest's Canadian mines are the Red Chris Mine and Brucejack Mine, both of which are located in northwest BC.

Pretium Resources Inc. is a corporation existing under the *Business Corporations Act* (British Columbia) and the permittee for Brucejack Mine authorizations.

Newcrest's regional office address and contact information is as follows:

Newcrest operations
800-1066 Hastings Street West
Vancouver, BC, V6E 3X1
Phone: 604-558-1784
Toll Free: 1-877-558-1784
Website: www.newcrest.com

Communications regarding the proposed 4950 tpd Joint Application should be directed to:

1.4 Project Overview

1.4.1 Project History

1.4.1.1 Exploration, Development and Ownership History

Exploration of the Brucejack Property and the surrounding region dates back to the 1880s, when placer gold was discovered in Sulphurets and Mitchell creeks. In 1935, prospectors Bruce and Jack Johnson discovered copper-molybdenum mineralization on the Sulphurets Property in the vicinity of a copper zone located approximately 6 km northwest of Brucejack Lake.

In 1960, Granduc Mines Limited (Granduc) and prospectors staked the main claim group covering the known copper and gold-silver occurrences, which collectively became known as the Sulphurets Property. The Sulphurets Property was a larger claim group that included what is now the Brucejack Property. Exploration was conducted by Granduc and Esso Minerals through 1984 evaluating high-

grade prospects including the West Zone (WZ). In 1985 Newhawk Gold Mines Ltd. entered into a 60:40 joint venture with Granduc to explore and develop the Sulphurets Property.

Between 1986 and 1991, Granduc (40%) and the Newcana (Newhawk Gold Mines Ltd. and Lacana Mining Corp., 60%) Joint Venture spent approximately $21 million developing the WZ and other smaller precious metal veins on what would later become the Brucejack Property. The historic WZ portal, which provided access for development of several km of underground workings during the late 1980's, dates from this time. The Sulphurets Project was also proposed and approved during this period under the Regional Mine Development Review Process in existence at that time. Waste rock and ore from the historic advanced exploration activity was subsequently deposited into Brucejack Lake in 1999 under direction of BC Ministry of Energy and Mines.

Between 1999 and 2001, Silver Standard Resources (now SSR Mining Inc.) acquired interest and control of the Brucejack Gold Mine Project, including 100% interest in the Brucejack Property. Silver Standard Resources began initial exploration work on the Brucejack area in 2006 and began a large diamond drilling campaign on the Brucejack Valley of the Kings (VOK) Zone in 2009.

Pretium acquired the Brucejack Gold Mine Project, along with other associated assets, pursuant to an acquisition agreement dated October 28, 2010.

In 2012, Pretium commenced an underground exploration program designed to access the VOK deposit, excavate a 10,000 t underground bulk sample and demonstrate continuity of the high-grade gold mineralization. In late December 2012, the widening of the historical WZ underground workings was completed and excavation commenced of the access ramp from the WZ workings to the VOK. The bulk sample was collected and processed to improve confidence in both the geological model and the ore grade estimate.

Following issuance of authorizations required for mine construction and operations during 2015, construction of the Brucejack Mine commenced in September 2015. Commercial production was declared on July 3, 2017. EA Certificate M15-01 authorizes production of up to 18.5 Mt of ore over the life-of-mine. *MA* Permit M-243 (Appendix 1-1) authorizes a mining rate of 1,387,000 t on a calendar year basis (average 3,800 tpd). *Environmental Management Act* Permits PE-107835 (Appendix 1-1) and PA-107025 regulate mine effluent and air discharges respectively.

Newcrest Mining Limited acquired Pretium and the Brucejack operation on March 9, 2022.

1.4.1.2 Previous Reports, Studies, and Design Information

Previous reports, studies, and designs relevant to the 4950 tpd Joint Application include:

1.4.1.2.1 Major Authorizations Applications / Submissions

- *Brucejack Gold Mine Project: Application for an Environmental Assessment Certificate/Environmental Impact Statement (Pretium, 2014);*
- *Applications for Mines Act and Environmental Management Act Permits (Pretium, 2015);*
- *3800 tpd Amendment Application for Permits M-243 and PE-107835 (Pretium, 2018b); and*
- *2020 Mine Plan and Reclamation Program Update (Pretium, 2020b).*

1.4.1.2.2 Key Supporting Technical Reports

- *Brucejack Gold Mine: Assessment of Long-Term Sludge Stability for In-lake and Underground Deposition (Lorax, 2016a);*
- *Characterization of Overburden at the Brucejack Mine Site (Lorax, 2016b);*
- *Characterization of Overburden at the Brucejack Mine Site - Memorandum (Lorax, 2016c);*
- *Brucejack Gold Mine: 2018 Water Quality Model Report in Support of Amendment Applications for Ore Production Increase to 3800 tpd (Lorax, 2018);*
- *Brucejack Gold Mine: 2020 Groundwater Model Review and Update (Lorax, 2020a);*
- *Brucejack Gold Mine: 2020 Water Quality Model Review and Update (Lorax, 2020b);*
- *Brucejack Gold Mine: 2020 Water Balance Model Review and Update (Lorax, 2020c); and*
- *Changes to Brucejack Mine Groundwater Quality Monitoring Program (Lorax, 2022).*

1.4.1.2.3 *MA/EMA* Annual Reports

- *2015 MA/EMA Annual Report (Pretium, 2016);*
- *2016 MA/EMA Annual Report (Pretium, 2017);*
- *2017 MA/EMA Annual Report (Pretium, 2018a);*
- *2018 MA/EMA Annual Report (Pretium, 2019);*
- *2019 MA/EMA Annual Report (Pretium, 2020a);*
- *2020 MA/EMA Annual Report (Pretium, 2021a); and*
- *2021 MA/EMA Annual Report (Pretium, 2022a).*

1.4.2 Location, Access and Land Use

The Brucejack Mine is a gold-silver underground mine located in northwest BC approximately 950 km northwest of Vancouver and 60 km north-northwest of Stewart (Figure 1.4-1). More specifically, the Brucejack Mine is located at 56.4637, 130.1857. Ground access to the mine is via the Brucejack Access Road (BJAR), an approximately 73 km all weather access road that extends west from km 215 of Highway 37 North, and that is authorized under Pretium's Special Use Permit (SUP) S25923. The BJAR provides year-round access to the mine and is primarily a gravel surface road except for a 12 km section that traverses the Knipple Glacier. Air access is via helicopter from Stewart or other local communities, or by charter fixed-wing aircraft to Pretium's Bowser Aerodrome located at km 50 of the BJAR.

The mine's mining, processing and other primary infrastructure (mine site) is located at the headwaters of Brucejack Creek at an elevation of approximately 1365 masl.

The Brucejack Mine, the BJAR and the Brucejack transmission line lie within the asserted traditional territory of the Tsetsaut Skii km Lax Ha, and portions lie within the Nass Area of the Nisga'a Nation as defined in the Nisga'a Final Agreement, and the asserted territory of the Tahltan Nation.

Figure 1.4-1. Brucejack Mine Regional Setting, Access and Tenures

The WRTSF has an area of approximately 81 ha; its original maximum depth was approximately 85 m. The WRTSF has a short ice-free season, generally occurring from July through October. The receiving environment for discharge from the WRTSF is Brucejack Creek, which flows into Sulphurets Creek, which is tributary to the North Unuk River (Figure 1.4-3). The receiving environment is non-fish-bearing from the WRTSF outlet to a fish barrier located more than 20 km downstream along Sulphurets Creek and several hundred metres upstream of its confluence with the North Unuk River (Figure 1.4-3).

Ice, rock and recently deglaciated areas dominate the surficial materials at the mine site and surrounding areas, with the mine site surface rock and areas north and south of it being gossanous (mineralized to surface) (Figure 1.4-4). Given this, the mine site is either non-vegetated or only sparsely vegetated and, with respect to land use at capability, serves as matrix habitat for wildlife moving through the area (i.e., habitat through which wildlife will move, but which does not provide life requisites). Extensive information on the baseline environmental / ecological conditions of the Brucejack Mine area can be found in the mine's 2014 application for an Environmental Assessment Certificate / Environmental Impact Statement (Pretium, 2014) and 2015 *MA/ EMA* Permits Application (Pretium, 2015).

Potential environmental effects associated with the Brucejack Mine identified through the 2014 pre-development and subsequent environmental assessments have and continue to be mitigated and managed through implementation of the mine's design and associated planned mitigation measures, and implementation of requirements under the various authorizations. The latter requirements include the mine's Environmental Management Plans, including 21 plans required under EAC #M15-01 Schedule B and additional plans required under other authorizations.

The Brucejack Mine primary infrastructure is located within four mining leases: 1038597 (53.6 ha), 1038598 (553.6 ha), 1038599 (35.7 ha), and 1038600 (107.2 ha), the outer extents of which are shown on Figure 1.4-1 and Figure 1.4-2.

Figure 1.4-2. Brucejack Mine Surface Plan End of 2022 and M-243 Permitted Mine Area

Figure 1.4-3 Brucejack Mine Water Monitoring Sites and Aquatic Receiving Environment

Figure 1.4-4. Mine Site Gossanous Terrain Setting as Viewed from Northwest to Southeast

1.4.3 Mine Components and Off-Site Infrastructure

1.4.3.1 Overview

Mine site facilities are an underground mine and related surface facilities, including:

- Underground mine with water management, electrical, and ventilation systems; underground crusher and conveyor connection to the mill; and mine openings, including two portals (WZ and VOK) and five raises (four currently developed);
- WZ pad with support infrastructure for the underground mine including a heavy duty shop, staging areas for waste rock, offices, covered storage, mine heater and associated propane storage and supply, fuel storage and dispensing, and diesel power station (DPS);
- Mill with ore processing equipment, a smelting furnace, a paste backfill plant, an assay laboratory, core processing facility, and a mine Water Treatment Plant (WTP);
- Camp including kitchen, recreation, laundry facilities, mine and mill dry facilities, medical clinic, administration/offices, potable water well and distribution system, potable water treatment plant, sewage treatment plant (STP), and solid waste management systems;

- WRTSF with a waste rock dump (WRD) for subaqueous waste rock deposition and into which tailings are also deposited (Figure 1.4-5);
- Surface water management system that includes a Contact Water Pond (CWP), a contact water collection and treatment system, mine dewatering facilities, and freshwater diversion channels;
- Various ancillary surface infrastructure, including waste handling facilities, including an incinerator, waste oil burners, and burn pits; mine and avalanche control explosives magazines; cement binder storage silo for pasting operations; warehouse, coverall storage and equipment laydown areas; surface heavy duty shop to service vehicles and mobile equipment; fire hall; communications systems; heli-pad; and mine site roads;
- Overburden stockpile; and
- Non-potentially acid generating (NPAG) rock quarry at BJAR km 72 (Figure 1.4-2).

Figure 1.4-5. Brucejack Mine and WRTSF as seen from east side of WRTSF looking westward (August 2022).

The portion of the BJAR located within the mining leases is included in the M-243 Permitted Mine Area (PMA), as is the northernmost 19 km of the 56 km Brucejack transmission line. The Brucejack transmission line extends south from the mine to an intertie near the Long Lake Hydro facility and connects to the BC Hydro grid.

A new surface heavy duty shop is currently under construction and will replace the existing shop in 2023. A new warehouse is included within the new heavy shop that is currently under construction. Mine components and infrastructure, including these upgrades, are described in greater detail in Chapter 3.

1.4.3.2 Underground Mine

The underground mine has been designed to extract ore through a combination of transverse long hole open stoping (LHOS) and longitudinal LHOS. Paste backfill is integral to the mine plan to maximize both ore recovery and mining productivity. Modern trackless mobile equipment is used for most mining activities. No changes to mining methods or rock mechanics criteria are proposed for the proposed ore production rate increase from the currently authorized 3800 tpd to proposed 4950 tpd. An increased mining rate will be achieved through increased rates of drilling and development, supported by additional battery electric vehicles.

Major underground mine infrastructure includes the primary jaw crusher, conveyors, ventilation raises, fans, heating system, pumping stations, electrical substations, explosives magazines, paste fill booster pump station, refuges, underground batch plant, mine communications, and other ancillary installations.

1.4.3.3 Mill

The overall mill process, which includes crushing, grinding, gravity / flotation and tailings dewatering, will remain the same with the proposed production rate increase. To facilitate the production increase from 3800 tpd to 4950 tpd, the following upgrades to the mill are anticipated:

- Grinding circuit: increasing cyclone feed capacity and associated piping
- Gravity separation/concentration: upgrading gravity feed pump capacity, gravity screen, and an additional Knelson concentrator
- Floatation: pre-floatation trash screen installation, rougher concentrate to cleaner floatation bypass, and floatation circuit pump upgrades

These upgrades will be completed within the existing mill structure and do not require additional surface disturbance or facility construction.

1.4.3.4 Waste Rock and Tailings Storage Facility

Waste rock and tailings generated by the mine are either deposited in the WRTSF or backfilled in underground mined out stopes. These methods of mine waste placement will continue with the 4950 tpd mine plan, as described in Chapter 3.

The previously approved 3800 tpd mine plan (Pretium 2018b) allows for deposition of approximately 11.9 Mt of tailings and 7.8 Mt of waste rock within the WRTSF during the LOM. The 4,950 tpd mine plan does not increase the overall tailings and waste rock deposition to the WRTSF. Actual deposition tonnages into the WRTSF at the end of 2021 are recorded to be 3.56 Mt of tailings and 5.74 Mt of waste rock. From 2022 until the EOM, the 4,950 tpd mine plan has 7.8 Mt of tailings and 2.0 Mt of waste rock reporting to the WRTSF, for a total LOM tonnage of 11.3 Mt and 7.9 Mt, respectively.

Waste rock deposition will continue at the existing south WRD and (pending regulatory approval) potentially at an additional east waste rock dump (EWRD) described in the 2015 MA/EMA Permits Application that is required for existing operations. As described in Section 3.5.3, the additional WRD crest length and stockpiling capacity at the EWRD site will provide contingency management options.

The WRTSF (including WRD) is described in greater detail in Section 3.5.3 WRTSF geotechnical considerations for the increased production rate and operational controls needed to address geotechnical requirements are presented in the Waste Rock and Tailings Deposition Plan (Appendix 3-1).

1.4.3.5 Other Infrastructure and Components

Based on assessment of power consumption requirements for the proposed 4950 tpd ore production rate, an increase in power supplied by BC Hydro will be required (from current 20 MVA to 35.5 MVA. This increase in power does not require changes to the existing transmission line. Details on the transmission line can be found in Section 3.5.6 Brucejack Mine is in the process of electrifying part of its underground mine fleet.

The explosives consumption rate will increase as blasting activities increase for the first few years of operations with the 4950 tpd production rate increase, but then steadily decrease through operations as the rate of blasting and explosive quantities decrease. Section 3.5.1.4 summarizes types of explosives used and Section 3.5.7 describes the explosives magazines.

Risks associated with increasing the number of concentrate shipments (truck transportation) have been considered. Safety and environmental risks associated with concentrate transport along the BJAR are managed through the mine's Health and Safety, and Environmental Management systems, and will continue to be managed through these systems with a higher number of shipments. Relevant EMS component management plans include the Spill Response Plan, Traffic and Access Management Plan, Wildlife Management Plan and the Air Quality Management Plan. The current number of return trips by concentrate trucks from the mine to Port of Stewart varies based on weather and related road conditions and other factors, but averages 8 to 9 return trips per 24 h period (i.e., less than 1 truck per hour in either direction). Based on a proportional increase of 30% in the number of concentrate truck return trips, there would be an additional 2 to 3 return trips per day (i.e., average total of approximately 1 truck per hour in either direction). This is still an extremely low hourly traffic volume.

No changes specific to the proposed production rate increase are required for the BJAR or for Knipple or Wildfire camps and their associated infrastructure.

1.4.4 Mine Development and Operations

1.4.4.1 Mining

The updated mine plan presented in Chapter 3 has been adjusted to account for an increased ore production rate of 4950 tpd and for reconfiguration of mining within the West and VOK Zones. The mine envelope remains very similar to extents presented in the 3800 tpd Amendment Application for Permits M-243 and PE-107835 (Pretium 2018b) and in the 2020 Mine Plan and Reclamation Program Update (Pretium 2020b), with similar vertical and lateral extents.

The mining methods for the updated 4950 tpd mine plan remain the same as present – i.e., a combination of transverse LHOS and longitudinal LHOS. Overall mine waste handling methods also remain the same, with waste rock and tailings either placed in the underground mine as backfill or deposited/discharged within the WRTSF, dependent upon operational needs. Modern trackless mobile equipment will continue to be employed in the underground mine.

Mining production will remain focused on the VOK zone until 2025 when stoping in the higher silver, lower gold grade WZ is expected to begin. The proportion of material mined in the WZ compared to the VOK will then increase over the remainder of mine life.

VOK ramp development will advance continuously to the vertical extents of the mine. Levels will continue to be developed and stoping will continue, with all VOK and WZ reserves being mined over the LOM. Development of the WZ ramp is currently in progress to allow production from the lower WZ blocks by 2025.

Mining of the WZ deposit will begin in 2024/2025, with a gradual increase to full production from this area in 2027. Development (i.e., access to stopes) requirements will decrease significantly in the last 3 years of mine life. Installation of the last required ventilation raise is scheduled for 2025. Internal raises will be developed within the mine as determined by scheduling requirements.

WRD development, tailings deposition and km 72 NPAG quarry seasonal operations will continue during the 2027 to mine closure period. No additional surface infrastructure beyond the vent raise described above is planned for the period from 2027 to mine closure.

Because the ore production rate will be higher, the mine life will decrease. End of operations with the 4950 tpd mine plan will be 2029 rather than 2032.

Underground mine geotechnical considerations for the increased production rate are presented in Chapter 3. Ventilation requirements are also presented in Chapter 3.

1.4.4.2 Mill Process

The minor mill upgrades required for the proposed production rate increase are described in Section 1.4.3.3. These upgrades will be completed within the existing mill structure and will not require additional surface disturbance or facility construction.

1.4.4.3 Water Management and Quality

The Brucejack Mine water balance model has been updated for the proposed 4950 tpd production rate (refer to Appendix 5-2) and to reflect minor changes to mine site water management since 2020. The mine's groundwater model has also been updated (refer to Appendix 5-1).

Increased rates of waste rock and tailings deposition to the WRTSF and of backfilling underground, and changes to overall waste rock and tailings quantities, have the potential to affect water quality predictions. Water quality model updates, presented in Appendix 5-3, include the 4950 tpd waste rock and tailings deposition rates, the updated groundwater model and the water balance model results, and updated source terms. Additional information is presented in Chapter 5 Modelling, Mitigation, and Discharges.

1.4.4.4 Effluent and Air Discharges

The updated water quality modeling report (Appendix 5-3) presents updated predictions for effluent quality at the Brucejack Mine's WRTSF discharge location, monitoring site BJ 3.10, and further downstream at site BJ 2.62. These predictions and proposed mitigations are presented in Chapter 5. An aquatic effects assessment is presented in Chapter 6.

There are no changes to regulated air discharges related to the production increase and therefore no amendments of PA-107025 are required.

This information is presented in greater detail in Chapter 5 Modelling, Mitigation, and Discharges.

1.4.5 Mine Design and Assessment Team

Pretium / Newcrest personnel and consultants who provided technical input or other major contributions to this application are listed in Table 1.4-1 along with their primary roles and professional designations. Signed and sealed acknowledgements by the Qualified Professionals responsible for application technical chapters and information are provided in Chapter 10. Technical reports included as appendices to the 4950 tpd Joint Application are signed and sealed by Qualified Professionals, as appropriate, within those reports.

Table 1.4-1. 4950 tpd Joint Application Authors and Major Contributors

Personnel	Company	Title	Application Primary Role	Degree/ Professional Designation
Ben Wither	Pretium Resources Inc. (Pretium) / Newcrest Mining Limited	VP HSE and Permitting	Application senior review	B.Sc., M.B.A.
Sylvia Van Zalingen		Director, Permitting	Application management, senior review, preparation Reclamation and Closure Plan (Appendix 4-1) and chapter 4 excluding biophysical description and reclamation research sections, and preparation sections 7.1 , 7.2.1, 7.2.4, 7.3 and 7.4	M.S., P.Ag.
Brett DeHay-Turner		Senior Hydrogeochemist	Application coordination, compilation and review, management mine plan chapter and mine plan interface for water modeling reports, preparation sections 3.1, 3.2, 3.5, 7.2.5, and chapter 8	M.Sc.., P.Geo.
Greg Norton		VP Government Relations & Social Performance	Preparation section 1.6	M.Sc.
Sabrina Lakhani		Superintendent, Social Performance	Preparation section 1.6	BSc, MRespResDev
Nick Scarcelli -Casciola		Manager, Regional Mine Planning	Preparation sections 3.2.4, 3.3, 3.4, 3.5.1	P.Eng.
Scott Laliberte		Mill Operations Superintendent	Prepared section 3.5.2.5, 3.5.2.6 and 3.5.2.7	B.A.Sc.
Michael Yakimchuk		Mill Manager	Review sections 3.5.2 and 3.5.4	B.A.Sc., P.Eng.
Laura Fredrickson		Permitting Specialist	Compilation and support of sections 1.1, 1.2, 1.4, 1.5, 2.5, 2.7.1, 2.8, 2.9, 7.2.6, and chapter 9	B.A.Sc., E.I.T.
Xavier Pinto		Senior Hydrologist	Preparation sections 2.2 and 2.6.1 and review section 2.5	M.Sc., P.Geo.
Caitlin Scinocca		Intermediate Geotechnical Engineer	Prepared section 3.5.1.9	P.Eng.
Woo Shin		Senior Geotechnical Engineer	Review section 3.5.1.9, 4.6.4, 4.6.5, and Appendix 4-1 sections 12.4 and 12.5	Ph.D., P.Eng.
Dinesh Devathasan		Chief Mine Engineer	Review sections 3.5.1.5.1, 3.5.1.5.2, 3.5.5, and 3.5.7	P.Eng.
Alison Shaw	Lorax Environmental Services (Lorax)	Senior Geochemist	Senior technical review for geochemistry and water quality, contributed to sections 2.3, 2.4 and 7.2.5, preparation of Chapter 5, Water Quality Model (Appendix 5-3), and Table 1.4-4 (rows 2-5)	Ph.D., P.Geo.
Robert Goldblatt		Senior Biologist	Preparation of Chapter 6, contribute to preparation of Chapter 5, the Water Quality model report (Appendix 5-3) and Table 1.4-4 (rows 1 and 6-8), and reviewer of sections 2.7, 2.8, 2.9, 4.6.2 and Chapter 7.	B.Sc., RPBio
Colin Fraser		Senior Hydrologist	Preparation of Water Balance Model (Appendix 5-2)	M.Sc., P.Geo.
Joseph Xu		Senior Numerical Modeller	Preparation of Groundwater Model (Appendix 5-1) and Water Quality Model (Appendix 5-3)	Ph.D.
Jane May		Chemical Engineer	Preparation of Best Achievable Technology study (Appendix 5-4)	B.A.Sc., P.Eng.
Patrick Mueller		Environmental Chemist	Preparation of Water Quality Model (Appendix 5-3)	B.Sc., P.Chem.
Laura-Lee Findlater		Senior Hydrogeologist	Preparation of Groundwater Model (Appendix 5-1); contributed to sections 2.6.2, 2.7.2, 4.6.3, 7.2.2, Table 1.4-4 (rows 9-15), and Section 12.3 of Appendix 4-1.	B.Sc., P.Geo.
Justin Straker	Integral Ecology Group (IEG)	Soil Scientist, Forest Ecologist	Preparation Reclamation and Closure Plan (Appendix 4-1) reclamation research content	M.Sc., P.Ag.
Jeffrey Kwok	WSP Golder	Geotechnical Engineer, Mine Waste Canada	Review sections 3.2.3 and 3.5.3	P.Eng.
Krystle Batiuk	Environmental Resources Management (ERM)	Senior Consultant, Scientist	Review section 1.4.7 (except Table 1.4-4)	B.Sc., M.N.R.M., P.Biol.
Jackie Lerner		Principal Consultant	Preparation section 1.4.7 (except Table 1.4-4), 1.6	Ph.D., EP
Jessica Lowey		Senior Consultant, Terrestrial Biodiversity Lead	Preparation of section 4.2.1 (paragraphs 2 and 3) and Appendix 4-1 [prepared or approved soils and vegetation content in sections 2.2 (paragraphs 3 to 6) and 2.3 (paragraphs 2 and 4), and has prepared section 3.2 Climate Change Considerations)]	M.Sc., P.Ag.
Wade Brunham		Partner, Scientist	Preparation of section 4.2.1 (paragraphs 1 and 4) and Appendix 4-1 [prepared or approved wildlife content within sections 2.2 (paragraphs 3 to 6) and 2.3 (paragraphs 2 and 4)]	M.Sc., RPBio
Rhonda Netzel	Practical Engineering Ltd.	Electrical Engineer	Preparation section 3.5.7	B.Ap.Sc., P.Eng., PE

1.4.6 Spatial Data

1.4.6.1 Proposed Permitted Mine Area

No changes to the PMA are required to accommodate the 4950 tpd production rate increase. There will be no requested change to the approved mine site end land use of matrix habitat for wildlife.

1.4.6.2 Physical Disturbance Proposed Annually for 5 years

No changes to surface disturbance are required to accommodate the 4950 tpd production rate increase.

1.4.6.3 Reclamation Proposed Annually for 5 years

The design of the Brucejack mine site has focused on efficient and essential use of surface disturbances. This total surface disturbance area is small (terrestrial infrastructure area of 55 ha) (Appendix 4-1, Figure 8.1-1) and almost all is needed for operations. Because of this small, intensively used footprint, progressive reclamation has not been possible to date and there are no opportunities within the next 5 years beyond the small-scale areas being used to support reclamation research (see Appendix 4-1, Section 3.7) and small areas of disturbance from surface exploration. Reclamation activities for mine operations infrastructure areas will be completed during mine closure.

1.4.6.4 Proposed Life of Mine Disturbance and Reclamation Program

Refer to Appendix 4-1 for the updated Reclamation and Closure Plan. The reclamation liability costing has been updated and is being provided under separate cover to the Chief Permitting Officer as per Code Section 10.1.3(i).

1.4.6.5 Environmental Sampling Stations

No changes to environmental sampling stations are required to accommodate the 4950 tpd production rate increase. The locations of environmental sampling stations associated with PE-107835 and PA-107025 are described in the Aquatic Effects Monitoring Plan (AEMP) provided in Appendix 9-1-4 and in the Air Quality Management Plan provided in Appendix 9-1-2, respectively.

1.4.6.6 Site Infrastructure

Brucejack Mine site infrastructure is shown in Figure 1.4-2, and described in greater detail in Chapter 2 and 4.

1.4.7 Concordance with Environmental Assessment Conditions

EAC #M15-01 for the Brucejack Mine was issued under the BC Environmental Assessment Act (2002) on March 26, 2015. Many of the EAC #M15-01 Schedule B conditions (i.e., Conditions 1, 2, 3, 4, 7, 9, 10 and 14) pertained to management plans that were to be prepared and submitted to the EAO; this has already occurred. Consistent with previous applications and reviews, any required updates to these management plans will be completed after the review of the 4950 tpd Joint Application is complete to incorporate changes resulting from the review. Four other Schedule B conditions (i.e.,

Conditions 5, 6, 8, 13 and 15) pertain to the BJAR or other areas outside of the mining leases. Table 1.4-4 lists EAC #M15-01 Schedule B conditions that are relevant to the Joint Application.

Table 1.4-2. Concordance of EAC #M15-01 Conditions with 4950 tpd Joint Application Sections

Condition No.	Condition Description	Section in the Joint Application
11	The Holder must provide the results, analyses, and interpretation of test work conducted to demonstrate the effectiveness of all components of the construction and operations water treatment plants, to the satisfaction of EAO, MEM and MOE, prior to Construction related to the Mine Site.	Section 5.6.4.6. Influent and Effluent Water Quality
12	The Holder must complete the interpretation of groundwater conditions to increase confidence in the following predictions: • Groundwater inflow rates during operations; • Post-closure groundwater flow rate through the underground workings, and associated rate and area of contact-water discharge to surface water; and • The time required for the underground workings to flood during the closure period. The evaluation, at minimum, must include the following components: • Interpreted hydrogeological cross section along a flow path from the underground workings to the interpreted area(s) of groundwater discharge after closure; • Improvements to and/or sensitivity analysis of the groundwater-model calibration to the magnitude and direction of vertical and lateral hydraulic gradients, and the amplitude of transient response to seasonal recharge and underground dewatering; and • Associated sensitivity analysis with respect to predictions. The Holder must provide the evaluation, to the satisfaction of EAO, MEM and MOE, prior to Construction related to the Mine Site.	Section 5.3 Groundwater Model and Appendix 5-1 Groundwater Model Report

A comparison of the Certified Project Description with the 4950 tpd Joint Application project changes is provided below in Table 1.4-3. Table 1.4-4 summarizes permitting-level issues raised and commitments identified during Environmental Assessment Review. To develop Table 1.4-4, the permitting issues and comments that were identified during the original EA process (as identified in Table 10.1-5 of the 2015 Joint MA/EMA Application) were reviewed, and any items relating to the currently proposed Project changes were extracted and compiled in a new table. The section of the current Application where these issues are addressed for the proposed Project changes were then identified in the final column of the table.

Table 1.4-3. Comparison of Certified Project Description with 4950 tpd Joint Application Project Changes

Certified Project Description Section	Certified Project Description Detail	4950 tpd Joint Application Project Changes
1. Project Overview	The Brucejack Gold Mine Project (Project) uses underground mining methods to extract gold and silver ore from veins located in a mountainous area in northwestern British Columbia (BC). Ore is extracted using the long-hole open stoping (LHOS) and longitudinal LHOS methods with a combination of rock and paste backfill. The underground mining operation uses diesel- and electric-powered mobile equipment via a decline ramp system.	N/A – No new mining methods or equipment proposed.
	The Project will produce up to a maximum of 18.5 million tonnes (Mt) of ore at the Mine Site. The Project uses crushing, grinding, flotation, and gravity separation to produce gold and silver concentrate as well as semi-pure doré bars. The mine area includes camp accommodations, office facilities, a mill building, water and sewage treatment plants, a power station and ancillary infrastructure for the Project.	N/A – Life of mine ore extraction to remain within the 18.5 Mt maximum, no new milling processes proposed, and mill building to house the same project components.
	The Project stores waste rock and tailings in Brucejack Lake and uses a waste rock and tailings paste to backfill underground voids.	N/A – No new mine waste placement methods proposed.
	Project access is via the up to 76-kilometre (km) Brucejack Access Road that includes a glacier road.	N/A – The project access road remains the same.
	The Project houses construction workers at Wildfire Camp, located near the junction of Highway 37 and the Brucejack Access Road, and Bowser Camp, located at the Bowser Aerodrome, as well as at temporary camps at the mine site and at Stewart. Operation workers will be housed at the Mine Site, Bowser Camp, Wildfire Camp, and the Knipple Transfer Area; two explosives storage and staging areas west of Knipple Transfer Area and east of Bowser Aerodrome, respectively; remote avalanche control systems; and various communications tower sites and beacons for the aerodrome.	N/A – No new camps proposed.
	The Project includes the Bowser Aerodrome, an upgrade of the historic airstrip in the upper Bowser River Valley east of Knipple Lake. The Project includes the Brucejack Transmission Line a new, up to 60 km transmission line.	N/A – No changes to air transport or transmission line.
1.1 Location and Current Access	The Brucejack property is located at 56°28'20" N latitude by 130°11'31" W longitude, which is approximately 950 km northwest of Vancouver and 65 km north-northwest of Stewart. The Project is located within the Regional District of Kitimat-Stikine.	N/A – Location of the Project is static.
1.2 Project Components		
1.2.1 Bowser Aerodrome and Camp	Up to a 1600 metre runway with taxiway and apron. Portable air terminal building and generator. Approach and navigation lighting and flight control beacons. Septic field. One permanent and one temporary camp. Soil stockpile area. Meteorological station	N/A – No changes to aerodrome facility or camp.
1.2.2 Brucejack Access Road	Upgrades to the existing exploration access road to support Project construction and operations. Use of the existing Wildfire Camp, existing Wildfire Equipment Laydown area, and auxiliary laydown area for the purposes of accommodation and staging during life of mine. Remote avalanche control systems and meteorological station. Re-establishment and use of the existing road from Bowser Lake landing to the Brucejack Access Road. Realignment of the existing Lakeshore Drive to support Project construction and operations. Bulk emulsion staging areas with facilities for storage of explosives and the transfer and storage of bulk emulsion containers. **Use of and access to quarry materials in the Brucejack Access Road Disturbance Area.**	N/A – No changes required to the access road, camps, or laydown areas.
1.2.3 Brucejack Transmission Line	Up to 60-km-long transmission line, including a right-of-way up to 100 metres wide, from the mine site to the Bowser River Valley and then south-westerly to connect with the provincial grid at the Long Lake Hydro Project near Stewart, tap interconnection plus a substation and related facilities at the mine site. Temporary laydown staging area near Tide Lake and at Bowser Camp to support construction of the transmission line. Temporary camps for Construction with related water supply, sewage treatment, camp waste disposal facilities and construction waste disposal facilities at Bowser Aerodrome. Temporary camp for Construction in Stewart, BC located on private property with access to municipal water and sewer services, camp waste disposal facilities and construction waste disposal facilities.	N/A - Power consumption requirements for the 4950 tpd were assessed and an increased power supply from BC Hydro from 19.4 MW to 35 MW has been requested. This increase in power does not require changes to the existing transmission line.
1.2.4 Knipple Transfer Area	Laydown area for the transfer of materials and equipment between highway vehicles and specialized vehicles for transport over the Knipple Glacier. Step-down electrical power substation. Permanent camp for Knipple Transfer Area workers and road maintenance crews. Potable water supply. Septic field. Fuel storage facilities. Fuelling station.	N/A – No changes to Knipple Transfer Area.

Certified Project Description Section	Certified Project Description Detail	4950 tpd Joint Application Project Changes
	Lab for the assay of mineral samples, mill process samples and water samples. Ancillary buildings, including a maintenance and emergency vehicle building and cold storage building. Camp waste disposal facilities including incinerator. Construction waste disposal facilities. Soil stockpile area	
1.2.5 Mine Site	Underground mine using LHOS and longitudinal LHOS methods with a combination of rock and paste backfill. Underground mine ventilation. Mill building to house the ore processing and water treatment equipment and related facilities. Construction and operations camps, and related kitchen, recreation, administration, sewage treatment, and waste management facilities. Ancillary buildings, including carpenters' shop, maintenance shop, truck shop, and cold storage building. Incinerator. Explosives and detonator storage facilities. Pre-production ore storage and waste rock transfer area, where underground mining vehicles will deposit waste rock for transfer to surface vehicles for disposal in Brucejack Lake. Fuel storage facilities. Diesel power station. Concrete batch plant. Equipment laydown areas. Water management facilities, including mine dewatering facilities, freshwater diversion channels, contact water collection **ditches, process water pumping system** and contact water collection pond. Potable groundwater well and pipeline. Construction phase water treatment plant. Operations phase water treatment plant. Underwater waste rock and tailings disposal in Brucejack Lake. Turbidity curtains within and near the outlet of Brucejack Lake. Site roads to connect mine area facilities. Water supply pipeline to gravel borrow source. Helipad. Non-potentially acid generating (NPAG) rock quarry and sand/gravel borrow source to provide material for construction purposes. **Storage of Potentially Acid Generating (PAG) waste rock at surface for a duration and in a location within the Mine Site area as determined by the British Columbia Ministry of Energy and Mines.** **Snow Melter.**	N/A – No changes to this list of Mine Site facilities / components.
1.2.6 Communications Towers	Five radio and microwave communications towers.	N/A – No change to communications towers.
Figure 1-1	**Overview Map of Brucejack Gold Mine Project Figure 1-1 (27 June 2022)**	N/A – No change to figure required.

Note: Plain text indicates language contained in the Certified Project Description attached as Schedule A to EAC #M15-01 in Amendment #2; bold text indicates revisions to the Certified Project Description subsequently ordered by the EAO in EAC Amendments #3 to 8.

Table 1.4-4. Summary of Permitting-level Issues Raised and Commitments Identified during Environmental Assessment Review and Related Sections of the 4950 tpd Joint Application

Organization, Comment Topic and Date	EA Review Comment Tracking ID#	Reviewer	Comment Summary	EA Review Response Provided	EA Review – Additional Comment	2015 Permitting Phase Response:	4950 tpd Joint Application Response:
Brucejack EAO Working Group Formal Review Comment Responses - October 31, 2014 and January 2015	49	Alaska Operations Unit, US EPA	Executive Summary, ES39. "In the Closure and Post-Closure Periods, total Se may occur at concentrations exceeding background conditions and guidelines in the quarry runoff." While there are no fish in the waters adjacent to the mine site, levels of selenium in ponded water have been known to be lethal to birds and wildlife so monitoring should include selenium and any necessary precautions taken if levels are high.	Selenium will be monitored as part of the Aquatic Effects Monitoring Program (AEMP) for the Project. Site-specific water quality models were developed to evaluate the potential effects of mining activities for the Project and included the conveyance of contact water associated with the quarry site to Brucejack Lake (Appendix 13C). No guideline exceedances for selenium were predicted to occur in Brucejack Lake for the expected case (base case) or any of the sensitivity analyses (Section 13.6.2, Appendix 13D) and thus potential effects to birds and wildlife due to selenium concentrations are not expected. However, water quality monitoring programs for the Project will be established as a requirement of the permits and licences under which the Project will operate (e.g., BC *Environmental Management Act* [EMA], MMER) to ensure regulatory compliance, monitor the effectiveness of mitigation measures, and to verify the predictions of the effects assessment. This will allow for adaptive management if effects on surface water quality and, by extension, birds and wildlife, are identified.	N/A	Selenium will be monitored as part of the Aquatic Effects Monitoring Plan (AEMP) for the Project presented in Appendix 6-I.	Selenium and other water quality parameters continue to be monitored according to requirements in PE-107835 and the AEMP. The AEMP is reviewed annually and updated if necessary. Results of aquatic effects monitoring are reported in the *MA/EMA* Annual Report for Mines Act Permit M-243, Effluent Permit 107835, and Air Permit 107025. Any updates to the AEMP are also reported in this *MA/EMA* annual report. Changes to the AEMP that are required due to the 4950 tpd mine plan will be noted in the *MA/EMA* annual report that follows the permit amendment date.
BC Ministry of Energy and Mines on Hydrogeology, Geochemistry, and Reclamation - December 2014 and January 2015	73	Andrew Rollo, Senior Environmental Geoscientist, MEM	1. The geological description provided in Section 5.4 and the mine development plans in Section 5.8 provide a reasonable basis for assessing whether samples included in the geochemical assessment adequately represent the mine development. If, during operations, the mine plan changes and additional resources are included in the mine development, further characterization work will be required. (Mines Act permit condition)	As noted, the comment will be addressed during the Mines Act permitting stage.	N/A	Comment noted. We anticipate that this will be a Mines Act permit condition if the mine plan changes.	Although the mine plan has changed, the geologic units to be excavated, exposed or disturbed have not changed. These geologic units have been well characterized through baseline studies and subsequent monitoring programs as per the ML/ARD Management Plan. Should new geologic units be encountered, characterization studies including static and kinetic tests will be initiated.
BC Ministry of Energy and Mines on Hydrogeology, Geochemistry, and Reclamation – December 2014 and January 2015	109	Andrew Rollo, Senior Environmental Geoscientist, MEM	35. MEM believes that the simplifying assumptions employed as part of the Brucejack water quality model are generally adequately reasonable and conservative. As part of the EA follow-up program to evaluate the performance of the water quality model, the assumptions incorporated into the Brucejack water quality model should also be re-evaluated and updated as more information becomes available through operational monitoring. (EA commitment and Mines Act permitting condition)	Comment noted. No response required.	N/A	Permit condition noted. No further response required. It is understood that the geochemical assessment and model predictions will need to be re-evaluated as more data becomes available.	The Brucejack Mine water quality model source terms underwent a comprehensive validation/calibration review and update as part of the 2020 Mine Plan and Reclamation Program Update (presented in Appendix 5.1.5 of the 2020 Update submission). The data sets used for source term derivation are reviewed on an annual basis and presented in the mine's Annual Reclamation Report. The source terms presented in the 4950 tpd Joint Application have been reviewed and updated using monitoring data sets and experimental data sets collected through to the end of 2021. The source terms, and the data used for their development, are described in detail in Section 3 of the water quality model report – Appendix 5-3 of the application.
Proposed Brucejack Gold Mine Project Environmental Assessment Certificate - Pretivm Responses to Comments from the BC Ministry of	154	Andrew Rollo, Senior Environmental Geoscientist, MEM	N/A	N/A	20. MEM appreciates that a water quality model calibration run has been included in the updated version of the water quality model. It provides a level of confidence that the model is able to recreate historical conditions at the Brucejack site reasonably well. As part of the follow-up program to evaluate the performance of the	Permit condition noted. No further response required. It is understood that this will be a *Mines Act* permit condition.	The water quality model has been updated and reviewed several times since the EA application was submitted, with a major calibration/ validation effort having been carried out for the 2020 Mine Plan and Reclamation Program Update. The 4950 tpd application incorporates the results of updated operational monitoring data and experimental data acquired through to the end of 2021. Calibration of key source terms and a review of WTP treatment efficiencies based on operational data has been carried out

Energy and Mines on Hydrogeology, Geochemistry, and Reclamation - December 2014 and January 2015					water quality model, future versions of the water quality model should reassess calibration to ensure that the model continues to reproduce historic conditions reasonably well (*Mines Act* permit condition)		for this application, as presented in Appendix 5-2.
Proposed Brucejack Gold Mine Project Environmental Assessment Certificate/Environmental Impact Statement (August 2014) - Pretivm Responses to Comments Received from the Ministries of Environment and Forest, Lands, and Natural Resource Operations, November 2014 and January 2015	8	BC Ministry of Environment, Kara Przeczek, EIA Biologist	**13.5.2.2 Metal Leachings/Acid Rock Drainage** 1) The plan is to maintain at least 1 m of water cover on tailings and PAG waste rock. How will this minimum water cover be maintained in the future? Has climate change been considered in long term projections? 2) Will the lime added to the paste backfill (which is the NAG tailings, correct?) also be sufficient to neutralize the acid generated by the waste rock used as fill in the underground? 3) What about displacement of water in Brucejack Lake as a result of disposal of waste rock and resulting effects on water level in the lake and flow in Brucejack Creek? 4) It is noted that dissolved arsenic may still occur at relatively high concentrations in the drainage water from the underground and that at closure, potential metal-leaching of arsenic will be actively mitigated by collecting seepage water from underground workings and directing it to the treatment plant for subsequent treatment and use/release with a reference to Chapter 5. However, in Section 5.15.1 it is noted that water treatment is not planned after operations although it will be used if necessary. Is the potential for ongoing water treatment incorporated into the closure costs and planning?	1) A concrete flow monitoring weir has been designed with an outlet level corresponding to 1364.5 masl, which is the average open water season lake level recorded the past two years. The final elevation of PAG waste rock will be a minimum of 1 m below this level. The weir will remain in place at closure to provide a long-terms Table outlet elevation. Climate change was considered in long term projections for the project; results are discussed in Section 7.2.3 Climate Change in Pretium Resources Inc., Brucejack Project Environmental Assessment - Water Management Plan dated June 6, 2014. (EA Application Appendix 5-C). 2) Paste backfill will consist of tailings and binding agents with a high neutralization potential, and the amount of paste backfill in the underground is significantly higher (by a factor of approximately 3) than the amount of waste rock. However, the question of whether the neutralization afforded by the paste backfill would be sufficient to neutralize the acid generated by waste rock has not been evaluated at this time. 3) Displacement of water in Brucejack Lake as a result of waste rock disposal was accounted for in the water balance model used to predict changes to flows in Brucejack Creek. This is noted in Section 5.7 and Figure 7-3 in Pretium Resources Inc., Brucejack Project Environmental Assessment - Water Management Plan dated June 6, 2014. (EA Appendix 5-C). 4) The potential for ongoing water treatment following closure was not incorporated into the closure costs and planning. It will be included in an updated closure cost estimate for the *Mines Act* and *Environmental Management Act* permit application.	1) Water lake level was not explicitly considered in the climate change assessment in Section 7.2.3 of the Water Management Plan, EA Appendix 5-c. Is the assumption that if precipitation increases outweigh increased evaporative losses by increased temperature and wind speed then water level in Brucejack Lake should not decrease?	Correct - that is the assumption.	The updated water balance model considering the increased production rate of 4950 tpd includes variable climate and climate change sensitivity model runs (Section 4.2.13 of Appendix 5-2) and the level of the WRTSF (formerly referred to as Brucejack Lake) is not predicted to decrease. Therefore, the minimum water cover will continue to be maintained.
Proposed Brucejack Gold Mine Project Environmental Assessment Certificate/Environmental Impact Statement (August 2014) - Pretivm Responses to Comments Received from the Ministries of Environment and	16	BC Ministry of Environment, Kara Przeczek, EIA Biologist	**13.6.1.3 COPC screening - Table 2-2 from Appendix 13-C** In addition, do any parameters without an approved or working BC water quality or CCME guideline increase as a result of project activities? If so these should be considered to determine whether there is any potential concern associated with these parameters. A lack of a BC or CCME guideline does not necessarily mean that the parameter has no impacts. It could be that there is insufficient data to support a guideline. For example, we do not have a hardness guideline, but recent research has	As discussed Section 13.6 of the Application, the scope of the water quality effects assessment is restricted to include modelled water quality parameters with an approved BC water quality guideline for the protection of freshwater aquatic life and the following parameters with working BC water quality guidelines: cadmium, nickel, chromium and thallium. This approach was presented to the BC MOE in a memorandum outlining the proposed multi-step COPC screening process and residual effects assessment for the Project; comments were provided by the BC MOE on 9-May-2014 which were responded to. It is noted that the water quality model is currently being updated as per requests received by the Ministry of Energy and Mines;	Hardness was not modelled in the updated WQ model.	Calcium and magnesium were modelled in the updated water quality model. Base case model results for Ca and Mg correspond to a hardness range of 24-105 mg/L as $CaCO_3$ at BJ 2.62. Baseline hardness at BJ 2.62 ranged from 19-56 mg/L. Therefore, the Project is expected to produce a moderate increase to hardness in Brucejack Creek.	Calcium and magnesium were also included in the 4950 tpd model. Results are reported in the appendix to the Water Quality Model Report (Appendix A of Appendix 5.3). The hardness range for the 4950 tpd Base Case model during operations is 28-59 mg/L. The peak during closure is 156 mg/L. It is expected that mitigations developed in the Closure Underground Water Quality Adaptive Management Plan and which are not included in the 4950 tpd model will reduce the peak hardness during closure.

Organization, Comment Topic and Date	EA Review Comment Tracking ID#	Reviewer	Comment Summary	EA Review Response Provided	EA Review – Additional Comment	2015 Permitting Phase Response:	4950 tpd Joint Application Response:
Forest, Lands, and Natural Resource Operations, November 2014 and January 2015			indicated potential issues with increased hardness and there is work in progress to develop guidance for hardness in BC. I noted that Ca, Mg, K, and Na were all modelled (Table 2.2 in Appendix 13C), but they would have been excluded from COPC screening because they do not have guidelines (Figure 13. In the Chapter 13). Did any of these parameters without guidelines increase as a result of project activities?	update water quality predictions and COPC screening results will be provided under a separate cover.			
Proposed Brucejack Gold Mine Project Environmental Assessment Certificate/Environmental Impact Statement (August 2014) - Pretivm Responses to Comments Received from the Ministries of Environment and Forest, Lands, and Natural Resource Operations, November 2014 and January 2015	22	BC Ministry of Environment, Kara Przeczek, EIA Biologist	**13.6.2.1 Brucejack Lake Outflow - Erosion and Sedimentation section** • 1) The use of flocculation agents is necessary to ensure tailings particles remain permanently on the bottom of Brucejack Lake. What flocculation agent is being proposed and has it been assessed for toxicity/impacts? • 2) TSS from waste rock deposition in the lake is expected to be mitigated by turbidity curtains and "other mitigation measures". What are these other measures? Make a reference to where they are discussed in the application. • 3) The conclusion is that water quality from BJ Lake will be suitable for year-round discharge and will not require treatment. This is based on a comparison to PCO and MMER discharge limits. Since the discharge is essentially 100% of the flows in BJ Creek this conclusion is really dependent on the results for the receiving environment site at BJ2.62.	1) The flocculation agent to be added to tailings has not yet been determined although Magnafloc 155, an anionic polymer, is being considered at this stage. The decision will be finalized and toxicity tests completed prior to the start of operations. 2) TSS from waste rock deposition in the lake will be mitigated by turbidity curtains. Other mitigation measures have been considered and may be identified for implementation in the near future as deposition plans are finalized. No other mitigation measures were described in the Application. 3) Yes, the conclusion that year-round discharge from the lake will not require treatment is dependent on predicted water quality at BJ 2.62. No treatment is planned. It is anticipated the discharge quality will not result in significant adverse environmental effects, will not exceed MMER requirements, and will be permitted by MOE under the BC *Environmental Management Act.*	1 & 2 will be considered in permitting	1) The flocculation agent to be added to tailings has not yet been determined. The decision will be finalized and toxicity tests completed prior to the start of operations. It is anticipated that identification of the flocculant to be used and results of toxicity tests will be required as a *Mines Act* permit condition. 2) Turbidity curtains are the primary TSS mitigation measure for Brucejack Lake discharge. If allowable TSS concentrations were exceeded, contingency measures would be undertaken, such as reducing the rate of waste rock deposition, as described in the Tailings and Waste Rock Management Plan (Appendix 6-O). In addition, Pretivm is undertaking field studies to refine the understanding of TSS migration within Brucejack Lake.	1) The flocculant being used for thickening of tailings is AN 910 VHM (manufactured by SNF Canada Ltd.). Section 12 of the Safety Data Sheet for AN 910 VHM reports results of toxicity testing on aquatic life. The tests found that AN 910 VHM did not cause acute toxicity to fish (Danio rerio) or invertebrates (Daphnia magna), and did not cause chronic toxicity to algae (Scenedesmus subspicatus), at the highest concentration tested (100 mg/L for all three tests). 2) The turbidity curtains in the WRTSF have effectively managed TSS in effluent. As well, results of TSS and turbidity monitoring of the WRTSF have been used to adaptively manage TSS at BJ 3.10 by depositing waste rock in the WRTSF in months with less potential for elevated TSS in surface water and stockpiling waste rock during months with higher potential for elevated TSS in surface water of the WRTSF.
Proposed Brucejack Gold Mine Project Environmental Assessment Certificate/Environmental Impact Statement (August 2014) - Pretivm Responses to Comments Received from the Ministries of Environment and Forest, Lands, and Natural Resource Operations, November 2014 and January 2015	28	BC Ministry of Environment, Kara Przeczek, EIA Biologist	**13.7.2.1 Characterizing Residual Effects: Mine Site Area - Change in Water Quality in the Receiving Environment** • "Predicted arsenic exceedances during Construction and initial Operation are likely attributed to the subaqueous disposal of waste rock to Brucejack Lake and the subsequent soluble elemental loads from this activity. These source terms are scaled based particle size distribution results for the purpose of relating laboratory test-work to field conditions. The upper end-member (i.e., most conservative) result was used in this scaling process." What is meant by the highlighted sentence? Is this related to suspended sediment particle size? • The exceedences for arsenic are noted as being low magnitude during all phases, with the HQ ranging from 1.1 to 1.6. However, this is a maximum guideline and the	The particle size distribution (PSD) referred to is not related to suspended sediment particle size. Here, the PSD refers to that of blasted waste rock, derived from laboratory test work during the exploration phase. The waste rock PSD was used to identify the proportion of the waste rock that is expected to be reactive; i.e. used to derive an appropriate scaling factor for the corresponding geochemical source term in the model. The proportion less than 2 mm was used. This is equal to approximately 16.5% (in the highest of 3 PSDs available). So, 16.5% of the total waste rock volume was considered to be reactive. This is being revisited and will be refined in the application to be submitted in the near future for an effluent discharge permit. The water quality model is currently being updated as per requests received by the Ministry of Energy and Mines. The characterization of potential arsenic exceedances will be reviewed and clarified once results are available from the updated model. However, in the Application/EIS, the maximum value reported for predicted water quality parameters do not represent the highest average month predicted, but instead, is the maximum single value observed	1) This was changed according to the presentation on December 11th. Revisiting in permitting. 2) See comment on #23(3) regarding "maximum single monthly value". Appendix 13-E shows arsenic exceeding the guideline during both high and low flows during construction and operations. The Updated Effects Assessment predicts exceedances of arsenic WQG during both low and high flow periods during Operations and Post-Closure. See MOE comments on the Updated Effects Assessment Based on Revised Water Quality Predictions for Brucejack Lake and Brucejack	1) The approach to the waste rock source term derivation (and the use of waste rock PSD to inform source term loading assumptions) is revisited in the permit application. 2) An updated effects assessment is provided for total arsenic in the permit application	Source terms used in the 4950tpd water quality model have been updated as described in the Water Quality Model Report (Chapter 3 of Appendix 5-3). An updated effects assessment for arsenic and other parameters of concern is also included the Water Quality Model Report (Chapter 5 of Appendix 5.3).

Organization, Comment Topic and Date	EA Review Comment Tracking ID#	Reviewer	Comment Summary	EA Review Response Provided	EA Review – Additional Comment	2015 Permitting Phase Response:	4950 tpd Joint Application Response:
			predicted value is a monthly mean, even the maximum predicted is still just a monthly mean. Note that baseline 95th percentile does not exceed the guideline and the HQ for maximum predicted to 95th percentile baseline ranges from 1.1 to 1.8 and the HQ for mean predicted to mean baseline ranges from 2.2 to 2.7 during base case conditions. Thus the concentration of arsenic in Brucejack Creek is being increased from baseline conditions and is predicted to exceed the maximum water quality guideline regularly whereas under baseline conditions it is not exceeded even at the 95th percentile of background concentrations.	in that month, at any point during the specified Project Phase. As the only guideline available, the maximum BC water quality guideline for arsenic (0.005 mg/L) was applied in step 1 of the COPC screening process for both maximum and mean predicted concentrations; there is an error in the Appendix table, where the maximum arsenic guideline should be stated (0.005 mg/L) instead of a '-'. As discussed in a memorandum provided to BC MOE on 8-May-2014, if predicted concentrations did not exceed BG WQG, they were screened out in the COPC identification process as guidelines are determined by the BC MOE to be protective of freshwater aquatic life receptors; therefore, there is no potential for adverse effects to water quality. Further, mean arsenic values were not chronically identified as a COPC for the Project; HQ > 1.0 for mean arsenic concentrations are restricted to low flow periods in Operations (Section 13.6, Appendix 13-E).	Creek (December 19, 2014)		
BC Ministry of Energy and Mines on Hydrogeology, Geochemistry, and Reclamation - December 2014 and January 2015	28	Hugh McCreadie, Associate, Senior Hydrogeologist for MEM and MOE	The water balance model for the BJL-H1 catchment does not seem to include leakage to the underground workings. The leakage rate might be small but has it been concluded that leakage will be zero? The current groundwater model seems to indicate almost zero leakage but that seems to be a by-product of a slip-up with the boundary conditions near the outlet of Brucejack Lake. Groundwater levels were very responsive to underground dewatering, seems likely that leakage from Brucejack Lake to underground would be non-zero. Recommendation: please include this component in the water balance or justify why it would not be included.	Please refer to the technical memorandum Brucejack Project – Environmental Assessment Information Requests from MOE and MEM – Hydrogeology - Part 1 of 3 (FINAL) dated December 17, 2014.	A relatively small leakage rate from Brucejack Lake to the underground workings is accepted. Nevertheless, please include this component in the water balance so that it's clear that it's been considered. (EA Information Requirement) Please note that, contrary to the response, the "proportion that flows to the underground workings vs. the larger regional flow system" can definitely be determined. Agreed that the current estimate of lake leakage is an insignificant proportion of the average annual lake water balance. Many mines operate in proximity to lakes with no adverse impacts but occasionally leakage rates are considerably larger than anticipated, usually because of unanticipated geological structures. Please outline the monitoring program and associated data review that will be implemented to confirm our current understanding of expected leakage rates from the lake. (Permit Information Requirement)	Proposed groundwater monitoring locations and frequency for construction, operations, closure and post closure are outlined in the MA & EMA Permits Application Water Management Plan (Section 7.4). One of the objectives of the monitoring plan is to develop an understanding of the sources of groundwater inflow to the underground (and specifically the influence of Brucejack Lake and Creek flows on underground water management). Leakage from Brucejack Lake to the underground workings is included on Figure 8.3-3 in the Water Management Plan and the adaptive management approach to understanding leakage rates from Brucejack Lake and Brucejack Creek is outlined in Section 6.5 and Table 6.5-1.	Seepage losses from WRTSF to the underground mine are simulated by the 4950 tpd groundwater model and discussed in Section 5.3.3 of Appendix 5-1. On an average annual basis, this loss is <100 m3/d and remains a very small (<5%) component of the underground mine water balance. Monitoring wells located east of the West Zone continue to provide groundwater level data that serve to calibrate the groundwater model in this area.
Proposed Brucejack Gold Mine Project Environmental Assessment Certificate - Pretivm Responses to Comments from the BC Ministry of	33	Hugh McCreadie, Associate, Senior Hydrogeologist for MEM and MOE	Wells MW-5A and 5B, and MW 12A seemed to respond more to dewatering than other wells that were closer to the workings. This phenomenon is often observed in fracture and fault-controlled bedrock groundwater systems. Please describe the drawdown response as a function of distance from the underground workings and discuss how this response informs the conceptual model. Please include a site plan that plots the	Please refer to the technical memorandum *Brucejack Project – Environmental Assessment Information Requests from MOE and MEM – Hydrogeology - Part 2 of 3 (FINAL)* dated December 19, 2014.	The pronounced heterogeneity of dewatering response suggests that **heterogeneity should be progressively incorporated into the model as the project proceeds.** Please continue to track and interpret the distance drawdown response as dewatering continues. (**Permit information**	Agreed: tracking and interpretation of the distance drawdown response will continue as dewatering continues. Additional detail on the adaptive management approach and its application to groundwater monitoring is provided in Section 6.5 and Section 7.4.2 of the Water	Continued monitoring of groundwater levels and underground dewatering rates since submission of the 2015 MA/EMA permit application has been used to inform the groundwater model, which underwent a major update in 2020. The 2020 groundwater model has been configured to simulated the 4950 tpd mine plan presented in this joint application (Appendix 5-1). The 2020 groundwater model introduced zonation in bedrock hydraulic conductivity values between lower lying areas and upland areas and simulated the Rainy and Brucejack

Organization, Comment Topic and Date	EA Review Comment Tracking ID#	Reviewer	Comment Summary	EA Review Response Provided	EA Review – Additional Comment	2015 Permitting Phase Response:	4950 tpd Joint Application Response:
Energy and Mines on Hydrogeology, Geochemistry, and Reclamation - December 2014 and January 2015			drawdown response of each piezometer.		**Requirement and Permit Condition)** Please submit the monitoring plan for the time period between now and permitting. (**EA Information Requirement)**	Management Plan, Appendix 6-R to the Application.	faults as permeable features (Section 3.2.6 of App 5-1). Thus, heterogeneity has been incorporated into the groundwater model since the 2015 submissions on an as-needed basis to optimize the model calibration. In 2018, a series of monitoring well pairs were installed across the mine the site which has served to supplement the water level record from baseline monitoring wells (including BJ-GW11-5A/B and BJ-GW12-12A/B). The data from these new well pairs has been used to validate the 2020 model. Overall, the model reasonably simulates observed water levels and underground dewatering rates indicating that the 2020 model calibration, and thus heterogeneity, is appropriate for predictive simulations of 4950 tpd mine plan (see Section 4.3 of Appendix 5-1). The groundwater model is also well-positioned to inform future decisions regarding monitoring frequency and locations of new monitoring wells required by permit PE-107835.
BC Ministry of Energy and Mines on Hydrogeology, Geochemistry, and Reclamation - December 2014 and January 2015	61	Hugh McCreadie, Associate, Senior Hydrogeologist for MEM and MOE	The direction of groundwater flowpaths illustrated on the figures is not clear. Are all flowpaths from the workings or some flowpaths are from and some are toward?	Please refer to the technical memorandum Brucejack Project – Environmental Assessment Information Requests from MOE and MEM – Hydrogeology - Part 1 of 3 (FINAL) dated December 17, 2014.	The point is taken that the text describes the direction of groundwater flow described by the pathlines on Drawings 32A and 32B. For future pathline figures, please include arrows on the pathlines or a note on the figure. (Permit information requirement)	Refer to Drawing 22 from the Brucejack Project MA/EMA Permitting Phase - Numerical Hydrogeologic Model Update Report. Drawing Note 5 specifies the direction of pathlines for both forward and reverse particle tracking scenarios.	Appendix 5.1 presents findings of the 4950 tpd groundwater model. Backwards particle tracks are presented for end of mine flow solution in Figure 5-6, while forward particle tracks for the closure flow field are shown in Figure 6-2. Legends in the figures indicate the direction of the particle tracks.
BC Ministry of Energy and Mines on Hydrogeology, Geochemistry, and Reclamation - December 2014 and January 2015	22	Hugh McCreadie, Associate, Senior Hydrogeologist for MEM and MOE	Permit Condition: The groundwater model should be updated with any future dewatering effects to improve the understanding of dewatering effects.	Please refer to the technical memorandum Brucejack Project – Environmental Assessment Information Requests from MOE and MEM – Hydrogeology - Part 1 of 3 (FINAL) dated December 17, 2014.	N/A	Agreed. The groundwater model predictions will be reviewed against observed effects and revised as needed to support active mining and adaptive management initiatives for closure and post-closure. It is proposed that this review would, at a minimum, be completed to coincide with 5 year mine plan submissions under the Mines Act.	The groundwater model was substantially updated in 2020 in support of the 5 Year Mine Plan and Reclamation Program update. The model was recalibrated to underground dewatering data and groundwater level data collected up until the end of 2018. The 4950 tpd Joint Application groundwater model has been validated against additional underground dewatering and water level data collected between 2019 and 2021. Results of the model calibration and validation are presented in Section 4.3 of Appendix 5.1.
BC Ministry of Energy and Mines on Hydrogeology, Geochemistry, and Reclamation - December 2014 and January 2015	64	Hugh McCreadie, Associate, Senior Hydrogeologist for MEM and MOE	Permit Information Requirement: The closure and post-closure groundwater monitoring plans will understandably have some uncertainties at this stage of the project. However, additional specifics are nevertheless required: • objectives of the monitoring (e.g., will the monitoring be used to evaluate whether all groundwater flowpaths are toward the underground workings?), • approximate or minimum number of monitoring wells (for example, sampling of four monitoring wells would be inadequate), • approximate depths of monitoring well completions (for example, sampling only from wells that are completed to depths of say 50 ft would be inadequate), whether groundwater will be sampled at multiple	Please refer to the technical memorandum Brucejack Project – Environmental Assessment Information Requests from MOE and MEM – Hydrogeology - Part 1 of 3 (FINAL) dated December 17, 2014.	To be reviewed as part of the permit application process	Groundwater monitoring objectives, locations, rationale etc. are considered in the MA & EMA Permits Application Water Management Plan (Section 7.4). The general objectives of proposed monitoring wells are outlined specifically in Section 7.4.2, and Tables 7.4-2 through 7.4-5 of the Water Management Plan.	A groundwater monitoring program following the recommendations of the 2015 EA and Permitting review comments was incorporated in PE-107835 and has been implemented by the mine. The extents of the 4950 tpd mine plan are generally very similar to the 3800 tpd mine plan with exception to (i) deeper and broader extents of the VOK mining area, (ii) new exploration developments advanced south, west and north of the VOK, and (iii) a vent raise developed north of Brucejack Creek. The current monitoring network outlined in PE-107835 remains well positioned to monitor the influence of the mine on the groundwater system and no changes are proposed at this time. Continue implementation of daily monitoring underground dewatering rates and high resolution groundwater monitoring are recommended, per Section 8.2 of Appendix 5.1.

Organization, Comment Topic and Date	EA Review Comment Tracking ID#	Reviewer	Comment Summary	EA Review Response Provided	EA Review – Additional Comment	2015 Permitting Phase Response:	4950 tpd Joint Application Response:
			depths at each location (for example, sampling only from wells that are completed at a single depth would be inadequate), • the rationale for the chosen post-closure monitoring locations and depths. Also, a monitoring duration of three years postclosure does not seem credible considering that groundwater moves quite slowly. A longer monitoring period is required along with the rationale for the duration of monitoring. Finally, the groundwater monitoring costs (Table 30.11-1) are quite low and therefore do not seem to include new monitoring wells. Some provision should be made for installing new monitoring wells in case they are necessary.				
Proposed Brucejack Gold Mine Project Environmental Assessment Certificate - Pretivm Responses to Comments from the BC Ministry of Energy and Mines on Hydrogeology, Geochemistry, and Reclamation - December 2014 and January 2015	66	Hugh McCreadie, Associate, Senior Hydrogeologist for MEM and MOE	Permit Information Requirement: Monitoring and inspection of sealed adit portals is not mentioned in Chapter 30 (Closure and Reclamation). Additional specifics will be required regarding the monitoring of adits and portals post-closure in Chapter 29 (Environmental and Monitoring Plans): • frequency and timing of checking for adit seepage, • criteria for determining whether the groundwater levels have reached maximum elevation, • analytical parameters of samples, whether or not flow will be monitored and by what method.	Please refer to the technical memorandum Brucejack Project – Environmental Assessment Information Requests from MOE and MEM – Hydrogeology - Part 1 of 3 (FINAL) dated December 17, 2014.	To be reviewed as part of the permit application process	Refer to response to IR #3165.	Monitoring of the post closure mine pool water quality and water levels is discussed in Section 12.3 of Appendix 4-1 of the Application. Seepage monitoring from portal plugs will be conducted in concert with geotechnical inspections ensuring that the plugs are operating as intended (Section 12.4 of Appendix 4-1).
BC Ministry of Energy and Mines on Hydrogeology, Geochemistry, and Reclamation - December 2014 and January 2015	67	Hugh McCreadie, Associate, Senior Hydrogeologist for MEM and MOE	Permit Information Requirement: Groundwater is a slow-moving pathway with potential for long-term, chronic impacts that become evident only years or decades after closure. Groundwater monitoring currently does not seem to be included in the post-closure monitoring program. Recommendation: include groundwater monitoring in the post-closure monitoring program.	Please refer to the technical memorandum Brucejack Project – Environmental Assessment Information Requests from MOE and MEM – Hydrogeology - Part 1 of 3 (FINAL) dated December 17, 2014.	To be reviewed as part of the permit application process	Groundwater monitoring in the closure and post closure periods is considered in Section 7.4.2 of the MA and EMA Permits Application Water Management Plan (WMP). Contingency for replacement of monitoring wells due to construction activities and installation of additional wells for operations/closure is considered in the WMP.	The frequency and duration of groundwater monitoring in the closure and post-closure periods is discussed in Section 4.6 of the main application document and Section 12.3 of Appendix 4.1. The discussion has included collection of monitoring data from wells proposed to be installed near closure (per PE-107835) and from the underground mine pool, per the Closure Underground Water Quality Adaptive Management Plan submitted in the 2020 5 Year Mine Plan and Reclamation Program Update.

1.5 Regulatory Framework

1.5.1 Current Authorizations

The Brucejack Mine received provincial EAC #M15-01 on March 26, 2015 and a federal *Canadian Environmental Assessment Act* (CEAA) 2012 Decision Statement on July 30, 2015. All the various provincial and federal authorizations required to construct, operate and decommission the mine were received in 2015. Surface construction activities began at the mine on September 5, 2015 and were completed mid-2017. Operations began in July 2017.

PA-107025 was issued on January 9, 2014, followed by *MA* Permit M-243 on July 22, 2015, and PE-107835 on August 31, 2015. In addition to the authorizations noted above, authorizations in place to enable the presence and operations of the mine and its supporting infrastructure include mining leases, water licenses and other *Water Sustainability Act* authorizations, *Land Act* tenures [Licenses of Occupation (LOO's) and a Statutory Right-of-Way (ROW)], a SUP for the portion of the mine's access road located outside of the mining leases, a cutting authorization, and many others.

Permits M-243, PE-107835 and PA-107025 have each been amended multiple times since their initial issuances. These amendments are summarized below in Table 1.5-1, Table 1.5-2 and Table 1.5-3.

Table 1.5-1. *Mines Act* Permit M-243 Amendment Summary

Amendment Date	Summary of Key Amendments
Issued August 26, 2015	Approving groundwater monitoring plan.
Issued September 9, 2015	Approving updated ML/ARD Management Plan.
Issued March 17, 2016	Approving temporary PAG waste rock stockpile and Non-PAG Quarry.
Issued August 4, 2016	Approving changes for disturbance area and construction Water Treatment Plant
Issued April 3, 2017	Approving PAG waste rock exposure extension, sludge deposition with tailings and Chromium Management Plan
Issued December 14, 2018	Approving Mine Plan and Reclamation Program for increased production rate and waste management
Issued December 18, 2020	Approving WZ Ramp, additional stope development, and underground exploration
Issued November 14, 2022	Approving PMA expansion for future access road realignment of the km 72 ramp
Issued August 1, 2023	Approving PMA expansion for km 72 NPAG quarry expansion

Table 1.5-2. Amendments to PE-107835 since issuance on August 31, 2015.

Amendment Date	Summary of Key Amendments
Issued February 4, 2016	Amended STP discharge rate and change of domestic wastewater treatment works (addition of temporary C25 treatment unit)
Issued July 12, 2016	Amended STP discharge rate, change of domestic wastewater treatment works (addition of second C75 treatment unit), revised CWP volume limits to reflect updated water balance, revised surface water quality monitoring requirements and non-compliance reporting schedules
Issued March 31, 2017	Amended surface water quality, WTP, and CWP monitoring requirements from updated water quality modelling and ecological effects assessment, authorization of subaqueous deposition of WTP sludge, references to updated ML/ARD Management Plan and Nitrogen Management Plan
Issued December 14, 2018	Amended thickened tailings slurry discharge rate to 3800 tpd, revised surface water quality discharge limits, groundwater monitoring requirements updated to include new monitoring well installations
Issued December 18, 2020	Amended STP discharge works to temporarily include third C75 treatment unit.
Issued June 16, 2022	Amended STP authorized works to permanently include third C75 unit and remove C25, administrative change of mine name from Brucejack Gold Mine to Brucejack Mine
Issued August 21, 2023	Amended groundwater monitoring requirements

Table 1.5-3. Amendments to PA-107025 since issuance on January 9, 2014.

Amendment Date	Summary of Key Amendments
Issued July 22, 2015	Amended authorized discharges to include fugitive dust, underground crusher ventilation raise, dust collection system, smelting furnace, assay lab exhaust, auxiliary fuel fired refuse incinerators, and miscellaneous sources
Issued July 12, 2016	Amended location of Brucejack Mine incinerator, number of burn pits, disposal of ash and residue from Brucejack and Knipple incinerators to authorize burial in soils and overburden at the Knipple Transfer Area, disposal of ash from open burning to authorize burial at sites adjacent to burn pits
Issued September 8, 2017	Amended to increase smelting furnace operating hours
Issued March 27, 2018	Amended location of Knipple Transfer Area burn pit
Issued July 8, 2021	Amended location of assay laboratory to the Brucejack Mine mill building and added assay lab discharges

1.5.2 Potential Amendments to Authorizations

The following describes potential or expected authorization amendment application requirements associated with the proposed increase to an average ore processing rate of 4950 tpd.

MA Permit M-243:

- Application to approve the updated Mine Plan and Reclamation Program.

- Increase the average annual ore production from 1,387,000 tpa to 1,806,750 tpa (Condition A.3.b).

Effluent Permit 107835:

- Based on water quality modeling results, increase discharge limits for arsenic and nitrate, and add discharge limits for dissolved copper and total selenium (Condition 1.1.1).

1.6 Indigenous Engagement

1.6.1 Background

The broader Brucejack Mine operations area, including the mine site with its primary mine infrastructure, lies within the traditional and ancestral lands of the Tsetsaut Skii km Lax Ha (Figure 1.6-1) and the Tahltan Nation (Figure 1.6-2), and within the Nass Area of the Nisga'a Nation as defined in the Nisga'a Final Agreement (Figure 1.6-3).

Background information on each of the affected Indigenous groups, including ethnography, language, land use setting and planning, governance, economy, and reserves, can be found in the 2014 EAC/EIS Application and the 2015 Brucejack Gold Mine Project Assessment Report (Assessment Report; EAO 2015) as indicated in Table 1.6-1,Table 1.6-2 and Table 1.6-3 below.

1.6.2 Asserted and Established Rights and Interests

1.6.2.1 Tsetsaut Skii km Lax Ha

The Brucejack Mine site and ancillary infrastructure, including the BJAR, are within the asserted traditional territory of the Tsetsaut Skii km Lax Ha.

Detailed information on Tsetsaut Skii km Lax Ha's current use of land and resources for traditional purposes, specific asserted Indigenous rights, potential effects of the Brucejack Mine on Indigenous rights and interests, as well as mitigation measures, can be found in the sections of the 2014 EAC/EIS Application and Assessment Report indicated in Table 1.6-1 below.

Table 1.6-1. References to Tsetsaut Skii km Lax Ha Information and Assessment of Impacts in the 2014 EAC/EIS Application and Assessment Report

2014 EAC/EIS Application	Assessment Report
Chapter 25 Assessment of Potential Effects to Current Use of Lands and Resources for Traditional Purposes Appendix 25-A Ethnographic Overview Report Appendix 25-B Tsetsaut/Skii km Lax Ha Nation Traditional Knowledge and Traditional Use Report Chapter 26 Assessment of Effects on Asserted or Established Aboriginal Rights and Interests	Section 23 Tsetsaut/Skii km Lax Ha

In summary, the Tsetsaut Skii km Lax Ha assert rights to hunt, fish, trap, and harvest berries and other food and medicinal plants throughout their traditional territory. Given mitigation measures, the residual effects of the Brucejack Mine were predicted to have an overall low level of impact on the Tsetsaut

Skii km Lax Ha's Indigenous rights and the mine was not expected to affect the ability of present and future generations to exercise their rights, or modify their customs and practices related to fishing (EAC Application Chapter 26, Section 26.7.1.4).

1.6.2.2 Tahltan Nation

The Brucejack Mine site is located outside of Tahltan Nation traditional territory. The easternmost portion of the BJAR is within Tahltan territory.

Detailed information on Tahltan Nation's current use of land and resources for traditional purposes, specific asserted Indigenous rights, potential effects of the Brucejack Mine on Indigenous rights and interests, as well as mitigation measures, can be found in the sections of the 2014 EAC/EIS Application and Assessment Report indicated in Table 1.6-2 below.

Table 1.6-2. References to Tahltan Nation Information and Assessment of Impacts in the 2014 EAC/EIS Application and Assessment Report

2014 EAC/EIS Application	Assessment Report
Chapter 25 Assessment of Potential Effects to Current Use of Lands and Resources for Traditional Purposes Appendix 25-A Ethnographic Overview Report Chapter 26 Assessment of Effects on Asserted or Established Aboriginal Rights and Interests	Section 22 Tahltan Nation

In summary, the Tahltan Nation assert rights to hunt, fish, trap, and harvest berries and other food and medicinal plants throughout their territory. Given mitigation measures to accommodate potential impacts, the overall effect on the Tahltan Nation's ability to exercise rights was expected to be low and was not expected to affect the ability of present and future generations to exercise their rights, or modify their customs and practices related to fishing, hunting, and gathering (EAC Application Chapter 26, Section 26.7.2.4).

1.6.2.3 Nisga'a Nation

The Nisga'a Final Agreement (NFA), a modern treaty and land claims agreement settled in 2000, gives the Nisga'a Nation a right to self-government and sets out in law specific treaty rights over lands and resources.

The Brucejack Mine site is located outside of areas and lands described in the NFA. However, the majority of the BJAR and Brucejack transmission line traverse an area of land defined in the NFA as the Nass Area, over which the Nisga'a hold treaty rights to harvest migratory birds, fish and aquatic plants.

Detailed information on Nisga'a Nation's current use of land and resources, treaty rights set out in the NFA, potential effects of the Brucejack Mine on treaty rights set out in the NFA, and mitigation measures can be found in the sections of the 2014 EAC/EIS Application and Assessment Report indicated in Table 1.6-3.

Table 1.6-3. References to Nisga'a Nation Information and Assessment of Impacts on Treaty Rights in the 2014 EAC/EIS Application and Assessment Report

2014 EAC/EIS Application	Assessment Report
Chapter 25 Assessment of Potential Effects to Current Use of Lands and Resources for Traditional Purposes Appendix 25-A Ethnographic Overview Report Chapter 27 Assessment of Nisga'a Nation Treaty Rights, Interests, and Information Requirements	Section 24 Introduction and Purpose Section 26 NFA 8(e) Environmental Effects Assessment Section 27 Nisga'a 8(f) Economic, Social and Cultural Well-Being Assessment

In addition to the 2014 EAC/EIS Application and Assessment Report, the BJAR Impact Assessment Report (ERM 2015b) assesses the potential effects of the BJAR on Nisga'a rights set out in the NFA. This report was prepared separately, in response to comments from the Nisga'a Nation, because the construction of the access road had been assessed in a screening-level environmental assessment and was not included in the scope of the 2014 EAC/EIS Application. Considering mitigation measures and the conditions to the EAC, the Brucejack Mine:

- was not reasonably expected to have adverse environmental effects on Nisga'a fishing rights or rights to harvest migratory birds (Chapter 10, section 8(e) of the NFA; see sections 26.9 and 26.12 of the Assessment Report); and
- was not reasonably expected to adversely affect the cultural well-being of the Nisga'a Nation (Chapter 10, section 8(f) of the NFA; see section 26.13 of the Assessment Report).

Potential Effects on Indigenous and Treaty Rights

As described in Section 25.4.3.1 of the EAC Application, the potential effects of the Brucejack Mine on Indigenous groups' current land and resource use included in the assessment were:

- Change in access or ability to access or use land and resource use areas;
- Change in quality of experience of the natural environment;
- Change in the abundance and distribution of resources; and
- Change to the quality of resources.

The proposed changes to the Brucejack Mine set out in this application—i.e., the increase to average daily ore production rate from the currently authorized average 3800 tpd to 4950 tpd—are not anticipated to further impact the Indigenous rights of the Tsetsaut Skii km Lax Ha or Tahltan Nation, or the treaty rights of the Nisga'a Nation set out in the NFA. The proposed increase in the ore production rate is not expected to change the anticipated effects of the Brucejack Mine on Indigenous peoples' rights to fish, hunt, trap or gather as assessed in the EAC Application, Assessment Report and the BJAR Impact Assessment Report for the following reasons:

- *Change in noise levels associated with the Brucejack Mine are expected to be negligible.*
- *No changes to visual quality are expected as a result of the increase in daily ore production and are therefore not anticipated to alter potential effects on Indigenous groups' quality of experience of the natural environment.*

- *The increase in daily ore production will not interact with wildlife or vegetation, and no effects on fish or fish habitat are expected – consequently, the proposed changes are not anticipated to alter the mine's potential effects on abundance and distribution of resources.*
- *The proposed changes are not anticipated to alter the mine's effects on the quality of resources, as no changes to effects on country foods are anticipated.*

Positive economic effects were identified in the Assessment Report associated with employment opportunities, but these were not characterized (the former *Environmental Assessment Act* did not require a consideration of positive effects). The proposed changes are likely to impact the Brucejack Mine's interaction with Indigenous groups' employment and economic opportunities given the anticipated shorter mine life (i.e., as a result of the ore production rate increase, the end of operations is anticipated in 2029 rather than 2032, and thus employment and economic benefits associated with it will end earlier than expected). However, with mitigation, there were no negative residual economic effects predicted at mine closure in the Assessment Report (see Section 18.6), and the proposed project changes are not anticipated to change this conclusion.

1.6.3 Engagement Efforts

Pretium's engagement approach involves actively exchanging information and listening to concerns and suggestions. Quarterly, Pretium meets with Nisga'a Lisims Government (NLG) Lands Department and Tahltan Central Government's (TCG) Lands Department to keep them informed of activities at the Brucejack Mine and activities that may require regulatory approvals or may have interest to the nation from an environmental or cultural impact perspective. These meetings create the opportunity to enhance the understanding of the project area's social, cultural, and environmental conditions and potentially adapt and improve the project.

The proposed production rate increase, and the present amendment application were discussed with the NLG during quarterly update meetings on June 30 and October 14, 2022, and February 13, 2023, and with the TCG on July 14, 2022. Pretium extended invitations to meet with the TCG in October 2022 but the parties were not able to meet due to mutual availability.

The project description for the 4950 tpd Joint Application and the draft JIRT was shared with the Tsetsaut Skii km Lax Ha, Nisga'a Lisims Government and Tahltan Central Government prior to submission to the Province to provide further details of Pretium's plan to submit a joint application to increase the Brucejack Mine ore production rate, and to seek early feedback on the planned application. As stated in the Project Description, feedback was being sought to help inform Pretium of any potential concerns with the planned application and support addressing these via pre-submission communications and/or through the application content. It was also intended to help advise Pretium of potential requirements, conditions, and options for the planned amendment applications.

Tsetsaut Skii km Lax Ha and Nisga'a Lisims Government did not provide comments on the project description or the JIRT. Tahltan Central Government provided comments on the JIRT and the Project Description via the EMLI MMO referral process for the JIRT. Pretium provided responses to the TCG comments via the JIRT Issues Tracking Table (ITT) and adjusted content of the 4950 tpd Joint Application as applicable.

2. BASELINE INFORMATION

2.1 Summary

Extensive environmental baseline information for the Brucejack Mine local and regional areas is provided in the 2014 EAC/EIS Application (Pretium 2014), the 2015 *MA/EMA* Permits Application (Pretium 2015), and the 2015 *MA/EMA* Annual Report (Pretium 2016). Baseline technical reports appended to the 2014 EAC/EIS Application include the:

- Brucejack Environmental Assessment: ML/ARD Baseline Report (BGC 2014a);
- Brucejack Gold Mine Project: Cumulative Surface Water Quality Baseline Report (ERM Rescan 2014b);
- Brucejack Project Environmental Assessment - Hydrogeology Baseline Report (BGC 2014b);
- Brucejack Gold Mine Project: 2012 Surface Water Hydrology Baseline Report (Rescan 2013a);
- Brucejack Project: 2012 Fish and Fish Habitat Baseline Report (Rescan 2013g);
- Brucejack Gold Mine Project: 2012 Wetland Baseline Report (Rescan 2013h);
- Brucejack Gold Mine Project: Wildlife Characterization Baseline Report (Rescan 2013b);
- Brucejack Gold Mine Project: Wildlife Habitat Suitability Report (Rescan 2013i);
- Brucejack Gold Mine Project: 2012-2013 Terrestrial Ecosystem Baseline Studies (Rescan 2014);
- Brucejack Gold Mine Project: Cumulative Aquatic Resources Baseline Report (ERM Rescan 2014a);
- Brucejack Gold Mine Project: Non-traditional Land Use Baseline (Rescan 2013d);
- Brucejack Gold Mine Project: Ethnographic Overview Report (Rescan 2013c);
- Brucejack Gold Mine Project: Métis Interests Desktop Study (ERM Rescan 2014c);
- Brucejack Gold Mine Project: Tsetsaut/Skii km Lax Ha Nation Traditional Knowledge and Traditional Use Report (ERM Rescan 2014d);
- 2012 Archaeology Baseline Report (Rescan 2013e);
- 2013 Paleontology Baseline Report (ERM Rescan 2013);
- Brucejack Gold Mine Project: 2012 Air Quality Baseline Report (Rescan 2013j);
- Brucejack Gold Mine Project: 2012 Noise Baseline Report (Rescan 2013k);
- Brucejack Gold Mine Project: Socio-economic Baseline Report (Rescan 2013l);
- Brucejack Gold Mine Project: Country Foods Baseline Assessment (Rescan 2013m);
- Brucejack Gold Mine Project: 2012 Visual Quality Baseline Report (Rescan 2013n); and
- Brucejack Gold Mine Project: 2012 Meteorology Baseline Report (Rescan 2013f).

Baseline information presented in the above-referenced reports was collected before mine construction was initiated in late 2015. Additional monitoring information collected from 2015 onward is documented in the *MA/EMA* Annual Reports (Pretium 2016; 2017; 2018a; 2019; 2020a; 2021a; 2022a).

The following subsections provide overviews of baseline and environmental setting information, as well as a summary of data collected from the various monitoring programs through to the end of 2021, where relevant.

2.2 Meteorology and Climate

The following provides a summary of meteorological conditions for the period from late 2014 through 2021. Additional details of meteorological and climate information for the baseline period (i.e., prior to mine construction beginning in late 2015) and for the 2015 through 2021 period are provided as follows:

- Baseline meteorological and climate conditions: Appendix 7-A of the 2014 EAC/EIS Application (Pretium 2014).
- Pre-application baseline (September 2014 through July 2023) meteorological and climate conditions (Appendix 2-1 of this Application).
- 2015 through 2021 meteorological data and information: annual Meteorological Monitoring Reports that summarize calendar year monitoring data and current state of understanding with respect to meteorological conditions. These annual Meteorological Monitoring Reports are included as appendices within each MA/EMA Annual Report (Pretium 2016; 2017; 2018a; 2019; 2020a; 2021a; 2022a).
- Greenhouse Gas Emission Reports under B.C. Regulation 249/2015. Verification of the 2021 Emission Report by an independent, third party is provided in Appendix 2-2.
- Additional characterization of the pre- 4950 tpd Joint Application condition with respect to meteorological and climate conditions: Section 2.3 of the Water Balance Model report provided as Appendix 5-2 of this application.

Effects of climate change on temperature and precipitation are discussed in Section 2.3.6 of the Water Balance Model report provided in Appendix 5-2.

Site-specific meteorological monitoring by Pretium began in 2009 at the Brucejack Lake meteorological station, 2010 at the Scott Creek station, and 2011 at Wildfire Creek meteorological station (Table 2.2-1). To provide data at specific infrastructure sites (Bowser aerodrome and Scott Pass) and a more representative site at the mine site (VOK), the original three stations were decommissioned in August 2014 and their components moved to three new locations: VOK meteorological station, Bowser meteorological station, and Scott Pass meteorological station (Figure 2.2-1, Table 2.2-1).

Each meteorological monitoring station consists of a 10 m tower instrumented with research grade sensors sited according to guidelines by Environment and Climate Change Canada (ECCC) (EC 2004), and the BC Ministry of Environment and Climate Change Strategy (ENV; previously BC Ministry of Environment) (BC MOE 2016). Instrumentation is programmed to record air temperature,

relative humidity, average wind speed and gusts, solar radiation, net radiation, atmospheric pressure and total precipitation.

Climate data for the VOK for the period 2014-2021 are summarized in Figure 2.2-2. Air temperature data confirm December, January, and February as the coldest months on average, whereas July and August are the warmest months of the year. Air temperature data also indicate the transition from winter (sub-zero) to warmer (above-zero) temperatures typically occurs between April and May each year, triggering onset of freshet flow conditions owing to melt out of local snowpack.

Measured data for VOK indicate approximately 60% of the annual precipitation signature is realized as snowfall based on precipitation occurring primarily as snow between October and April, versus liquid precipitation (40%, rainfall) which occurs mainly between May and September each year. Local snow depth records show packs reach their maximum depth (2.5-4.2 m) by late winter (i.e., March, April or early May) (Figure 2.2-2, lower panel) and snowpacks ablate through May and June at the mine site following onset of warmer climatic conditions in the spring.

Table 2.2-1. Climate Station Locations and Operating Periods

Meteorological Station	Elevation (masl)		UTM Coordinates[1]		Operating Period	
		Status	Easting (m)	Northing (m)	Start	End
Brucejack Lake	1,360	Historical	425,729	6,259,022	Oct. 13, 2009	Aug. 30, 2014
Scott Creek	780	Historical	451,418	6,254,104	July 29, 2010	Aug. 27, 2014
Wildfire Creek	720	Historical	470,397	6,256,874	Aug. 13, 2011	Aug. 26, 2014
VOK	1,501	Current	426,301	6,258,276	Sept. 2, 2014	Active
Bowser	440	Current	443,003	6,250,540	Sept. 4, 2014	Active
Scott Pass	990	Current	456,394	6,262,968	Sept. 5, 2014	Active

Figure 2.2-1. Schematic showing the Location of Brucejack Mine Climate Stations and Snow Courses

Figure 2.2-2. Time series plots for VOK climate station (2014 to 2021). Plots presented in the figure show patterns and trends in precipitation, air temperature, relative humidity, wind speed and snow depth.

2.3 Geology

The geology of the Brucejack Mine area has been presented previously in various reports including Appendix 5-B of the 2014 EAC/EIS Application (Pretium 2014), Section 2.2 of the 2015 *MA/EMA* Permits Application (Pretium 2015), and Section 1.3 of the Technical Report on the Brucejack Gold Mine (Tetra Tech 2020).

The Brucejack deposit is located on the western side of the Stikine Terrane in the Intermontane morphogeologic belt of the Canadian Cordillera and is currently defined as incorporating the VOK zone and West zone. The Brucejack deposit occurs in an exceptionally metals-rich tectonic assemblage hosted in volcanic island arc-related rocks in BC's Golden Triangle. The deposit is interpreted to be a deformed, porphyry-related transitional to intermediate sulphidation epithermal high-grade gold-silver deposit.

At the district level, the Brucejack deposit forms part of a well mineralized, north-south gossanous trend (the Sulphurets Mineral District) associated with a regional unconformity and proximal mineralized Early Jurassic porphyry intrusions on the eastern limb of the McTagg Anticlinorium. Rocks of the Sulphurets Mineral District record a long history of volcanism, telescoping magmatic-hydrothermal alteration, mineralization, and deformation.

The mine area is largely underlain by volcano-sedimentary rocks of the Lower Jurassic Hazelton Group. These rocks unconformably overlie volcanic arc sedimentary rocks of the Upper Triassic Stuhini Group. The main lithological units encountered within the mine area and which have been characterized through baseline studies, as well as subsequent monitoring programs, include the following:

- P1 [Office or Bridge]: Hornblende, feldspar phyric latite flows.
- P2: Megacrystic, plagioclase, potassium-feldspar, and hornblende phyric flow.
- V12 [Fragmental volcanics]: Hornblende and/or feldspar phyric latite to andesite fragmental volcanic rocks and subordinate flows with minor ash and lapilli tuff.
- S3-Poly [Polymictic conglomerate]: Heterolithic boulder to coarse cobble conglomerate with sandstone.
- Silicified Cap: Silicified rocks; typically, poorly sorted heterolithic conglomerate, lesser sandstone, and local mudstone; commonly includes rhyolite fragments.
- VSF [Volcanic Sedimentary Facies]: Volcanically derived siltstone and sandstone with minor arenite and pebble conglomerate.

If new lithological units are encountered as mine development proceeds, these units will be characterized, assessed, and managed following procedures outlined in the mine's ML/ARD Management Plan.

The surficial materials within the Brucejack area consist of a sparse veneer of well-graded glacial till overlying bedrock. Grain size varies from sand to gravel, with some silt and clay, and variable quantities of cobbles and boulders. The thickness of unconsolidated deposits varies at the site but is generally less than 5 m and commonly less than 1 m (BGC 2014a).

A geohazards map for the mine site is presented in in the Geohazards Management Plan (Appendix 9-2-3).

2.4 Geochemical Characterization and Source Terms

The geochemistry of rock that has been or will be disturbed, excavated, or exposed at the Brucejack Mine has been characterized through static and kinetic test programs as described in the ML/ARD Baseline Report (BGC 2014a), the 2020 ML/ARD Review and Update (Pretium 2020c), as well as in the *MA/EMA* Annual Reports (Pretium 2016, 2017, 2018a, 2019, 2020a, 2021a, 2022a). The characterization programs have also evaluated the water quality impacts of explosives used for blasting and cement products used in shotcrete and paste backfill. Static tests include acid base accounting (ABA) analyses to evaluate if material is PAG, elemental analyses to identify parameters that are elevated and of potential concern and shake flask extraction tests to provide an indication of soluble loads and drainage chemistry. Kinetic tests including field bins, humidity cells and saturated columns have been carried out to assess the long-term behaviour of materials under site-specific conditions.

Summaries of the baseline study results, and recent monitoring results related to geochemistry and mine impacted water are described below:

- Waste Rock: static and kinetic test results from six lithologic units (described in Section 2.3) indicate that rocks from all units are dominantly PAG (83%) with elevated concentrations of metals (e.g., silver, cadmium, zinc) and metalloids (arsenic, antimony) compared to continental crust. Many of the PAG samples contain significant amounts of carbonate minerals (mostly calcite) that will neutralize acidity generated and prolong the onset to acid generation (Pretium 2016). Confirmatory sampling results through to the end of 2021 remain consistent with the baseline assessment (Pretium 2022a).
- Ore, tailings, and paste backfill: The ore is characterized as PAG with elevated concentrations of silver, arsenic, cadmium, manganese, and selenium, compared to continental crust (BGC 2014a). Thickened tailings generated from the mill show the same metal enrichments, but samples are predominantly NPAG (Pretium 2018a, 2019). Paste samples are similar in composition to thickened tailings, but with a slightly higher median neutralization potential ratio (NPR). Confirmatory sampling results through to the end of 2021 remain consistent with the baseline assessment (Pretium 2022a).
- Quarry rock: The km 72 NPAG Quarry is comprised predominantly of volcanic (plagioclase-hornblende) porphyry, with lesser amounts of conglomerate, and has negligible sulfide mineralization. Characterization studies of the km 72 NPAG Quarry rock samples have confirmed that rock excavated from the km 72 NPAG Quarry is consistently NPAG, with low neutral metal leaching potential. Confirmatory sampling results through to the end of 2021 remain consistent with the baseline assessment (Pretium 2022a).
- Underground mine water: Underground mine water at the Brucejack Mine is dominantly comprised of groundwater with added geochemical loads from blasted rock, wall rock, waste rock backfill, and paste backfill. Despite the prevalence of PAG waste rock, the neutralization afforded by carbonate minerals is expected to buffer any acid generated from sulphide oxidation reactions for several decades or more (Pretium 2015). Confirmatory sampling results through to July 2022 suggest there are no sustained increases in dissolved metals associated

with the onset of ML/ARD as predicted by kinetic tests (e.g., cadmium, cobalt, copper, iron, zinc) since gold production commenced in June 2017 (Pretium 2022a).

- Water treatment plant effluent and associated treatment residues (i.e., sludge): The WTP effluent has consistently met design specifications. Sludge generated from the WTP is co-deposited with thickened tailings in the WRTSF. Static test results indicate that the sludge is NPAG with elevated concentrations (greater than 10x average continental crust concentrations) of several metals (e.g., silver, arsenic, cadmium, manganese, molybdenum, antimony, and selenium). The results show that the sludge is stable under a range of pH and redox conditions and low metal leaching rates are expected for the co-deposited tailings and sludge. Confirmatory sampling results through to the end of 2021 remain consistent with the baseline assessment (Pretium 2022a).
- Excavated surface rock exposures and runoff: Non-contact surface runoff from areas immediately surrounding the mine site are directed to the WRTSF via the East (Johnson Creek) Diversion Channel, and to Camp Creek via the West (Camp Creek) Diversion Channel. Camp Creek runoff is naturally acidic, with elevated metal concentrations (e.g., silver, cadmium, copper, and zinc). The water quality of Mine Site contact water is assessed based on drainage into the CWP and shake flask experiments carried out on all surface exposed rock units.
- Explosives-related residues: Explosives-related residues contain water soluble nitrogen compounds that can affect water quality in the receiving environment. Site monitoring data have been used to derive and refine water quality predictions with respect to these compounds (Lorax 2020b).

The results of the baseline characterization studies have informed the development of the mine's ML/ARD Management, Nitrogen Management, Chromium Management and Closure Underground Water Quality Adaptive Management plans which are designed to prevent or minimize potential geochemistry and chemistry related adverse environmental effects associated with development, operation, and closure/reclamation of the Brucejack Mine. The monitoring programs described in the plans are also used to verify and update source terms for the mine's water quality model. The source terms used to develop the water quality model for the 4950 tpd application are described in detail in the water quality model report (Appendix 5-3).

2.5 Topography and Surface Drainage Features

The Brucejack Mine site is located in a bedrock controlled, high elevation area (Figure 2.5-1) and is located above the tree line in the Coastal Mountain-heather Alpine (undifferentiated; CMAun) Biogeoclimatic Ecosystem Classification (BEC) zone. Pre-mine, and in remaining undisturbed or minimally disturbed areas, the bedrock surface was/is irregular with rounded surfaces broken by crevices and depressions where snow accumulates. There were localized areas with shallow, slightly weathered overburden and limited areas with developed soil cover. Bedrock and shallow overburden extended to the lake shoreline, with few level areas.

The Brucejack Mine site is situated within the Brucejack Creek watershed, which is a small headwater sub-basin within the Sulphurets Creek watershed (drainage area 299 km^2). Brucejack Creek drains into Sulphurets Creek before reaching the Unuk River (Figure 1.4-3), which flows southwest, eventually discharging to the Pacific Ocean northeast of Ketchikan, Alaska.

Most of what is now the mine site drained to Brucejack Lake (now the WRTSF, Figure 1.4-5), with some areas draining to Camp Creek or directly to Brucejack Creek (Figure 2.5-3 and Figure 2.5-4). Refer to Brucejack Gold Mine Project: 2012-2013 Terrestrial Ecosystem Baseline Studies for additional baseline information on topography and surface drainage features (Rescan 2014).

Operations drainage patterns differ from baseline, as described in Appendix 4-1 Section 3.3.1.1, where Figure 3.3-3 shows the operations contact water collection system. The Water Management Plan – OMS Manual describes operations surface water drainage patterns in greater detail (Pretium 2021a, Appendix 3-1-1-9). The WRTSF receives mine waste and treated effluents and is the headwaters to Brucejack Creek.

Additional inputs to Brucejack Creek downstream of the mine's final effluent discharge compliance point (BJ 3.10) within Pilsner Valley (upper elevation section of Brucejack Creek) include natural seasonally acidic tributaries traversing the gossan to the south and east (Camp Creek and VOK Creek) and a small, circum-neutral pH tributary (Unnamed Creek) draining to Brucejack Creek from the north. Camp Creek, VOK Creek and Unnamed Creek are seasonally dry.

Figure 2.5-4: Pre-Mine Drainage Areas

2.6 Water Quantity

2.6.1 Surface Water Quantity

A summary of hydrological conditions for the period 2014 to 2021 is provided below. Additional details of hydrological information for the baseline period (i.e., prior to mine construction beginning in late 2015) and for the 2015 through 2021 period are provided as follows:

- Hydrometric monitoring network: described in the 2021 Hydrometric Monitoring Report included as Appendix 5.2-1 of the 2021 MA/EMA Annual Report (Pretium 2022a) and in Section 2.4 of the Water Balance Model report provided as Appendix 5-2 of this application.
- Baseline hydrological conditions: provided in Appendix 10-A of the 2014 EAC/EIS Application (Pretium 2014).
- 2015 through 2021 hydrometric data and information: provided in annual hydrometric monitoring reports that summarize calendar year monitoring data and current state of understanding with respect to streamflow conditions within the Brucejack Creek watershed. These annual hydrometric monitoring reports are included as appendices within each MA/EMA Annual Report (Pretium 2016; 2017; 2018a; 2019; 2020a; 2021a and 2022a).
- Additional characterization of the pre- 4950 tpd Joint Application condition with respect to hydrological conditions: Section 2.4 of the Water Balance Model report provided as Appendix 5-2.

The Brucejack Mine site lies within the Coast Mountains of northwestern British Columbia. The region is characterized by steep, rugged, high elevation topography with substantial glacier coverage receiving relatively high amounts of precipitation. The wet climate and physiography of the region result in dynamic watercourses with high annual runoff rates and high average stream flows, making water resource management an important component of mine operation and closure planning.

The Brucejack Creek catchment (drainage area 8.5 km^2 at water monitoring station BJ 1.74) is a small headwater sub-basin within the larger Sulphurets Creek watershed (drainage area 300 km^2 at the confluence with the Unuk River). The catchment is in a glaciated, alpine environment, with its uppermost portion flowing into the WRTSF (drainage area 6.7 km^2 at BJ 3.10). About 17 km downstream of Sulphurets Lake, Sulphurets Creek meets with the larger Unuk River which ultimately flows into the Pacific Ocean, northeast of Ketchikan, Alaska (Figure 2.6-1).

The Brucejack Mine hydrometric monitoring network includes four active hydrometric monitoring stations (Table 2.6-1, Figure 2.6-2 and Figure 2.6-3).

Table 2.6-1. Hydrometric Monitoring Network

Monitoring Station	Location	Easting a	Northing	Elevation (masl)	Drainage Area (km2)	Glacier Cover (km2 [%])	Period of Record	Monitoring Type
BJ 1.74	Brucejack Creek	425,739	6,259,085	1,349	8.5	0.82 [9.6]	2008 to present [b]	Continuous Stream Water Level
BJ WRTSF	Western shore of WRTSF near outflow	427,112	6,258,918	1,375	6.7	0.71 [11]	2013 to present	Continuous Lake Level
BJ 3.10	Brucejack Creek at WRTSF outflow	426,859	6,258,921	1,373			2018 to present	Continuous stream level and discharge [c]
SC-1	Sulphurets Creek downstream of the outlet of Sulphurets Lake	419,911	6,261,307	546	75.7	34.5 [46]	2016 to present	Continuous Stream Water Level

[a] UTM Zone 9U, NAD 83
[b] Originally BJL-H1, relocated to BJ 1.74 in 2014.
[c] Discharge measurements conducted on the channel downstream from the weir. No visible tributaries are located between the station and gauging section.

Watershed	Area (km^2)
Bell-Irving River	5338
Brucejack Creek	9
Unuk River (at international border)	1504
Salmon River	250

Figure 2.6-1. Regional Watershed Map

Figure 2.6-2. Hydrometric Stations at the Brucejack Mine

Figure 2.6-3. Brucejack Hydrometric Network

Snowmelt dominated streams, such as Brucejack Creek, tend to have relatively stable regimes especially in drainages where more than 5% of their areas are covered by glaciers, which act as runoff regulators of interannual variability (Eaton et al 2010). These runoff generating processes create the flow regime of Brucejack Creek, which is illustrated in the hydrograph provided in Figure 2.6-4. The low-flow period occurs through winter (December to March) when precipitation accumulates in the snowpack. High flows are associated with snowmelt following the onset of spring freshet in late-April to mid-May. Annual peak flows in Brucejack Creek occur in late-June. Flows ebb after this period until late-September to late-November when runoff is usually increased by sustained precipitation events.

Figure 2.6-4. 2021 Annual Mean Daily Discharge at Station BJ 3.10 (percentiles calculated using data for period 2014-2020)

The flow regimes of BJ 1.74 and BJ 3.10 are highly similar where daily/monthly patterns of streamflow are strongly influenced by snow accumulation and snowmelt processes; roughly 85% of runoff on an annual basis is expected to report to receivers between May and the end of October. By comparison, discharges and runoff depths for other months of the year (*i.e.,* November through April) are much lower. Winter streamflow rates are well characterized within the Brucejack Creek watershed and typically range between 0.05-0.120 m^3/s at BJ 3.10 between December and April. The transition from annual low flow conditions coincides with warmer air temperatures in the spring and the melting of snowpack. Measured discharges through open-water (ice free) months typically range between 0.5-2.5 m^3/s (Figure 2.6-5 upper panel, at BJ 3.10).

Figure 2.6-5. Streamflow measurements below the WRTSF outlet (BJ 3.10) for the period 2014-2021. Data for the station is presented in time series (upper panel) and flow duration curve format (lower panel).

2.6.2 Groundwater Quantity

The Brucejack Mine groundwater system has been characterized through several hydrogeological field investigations which have established a broad monitoring well network within and proximal to the mine. The current monitoring network is comprised of 31 monitoring wells as prescribed by Appendix B of Effluent Permit PE-107835 (BJ-GW18-22A was destroyed in 2022, and replacement is under review) (refer to Appendix 1-1 for Effluent Permit PE-107835). Appendix B of PE-107835 specifies monitoring locations, monitoring frequency and monitoring parameters for the groundwater monitoring

program. Four additional monitoring wells are monitored outside of permit requirements. Well locations, monitoring intervals and frequency are listed in Table 2.6-2. Currently monitored wells are shown in Figure 2.6-6.

Baseline groundwater quantity is summarized in Section 6 of the Brucejack Project Environmental Assessment Hydrogeology Baseline Report (Hydrogeology Baseline Report; BGC 2014b) which comprises Appendix 9-A of the 2014 EAC/EIS Application (Pretium 2014) and has been included as Appendix 2-3 to this Application. Data presented in the Hydrogeology Baseline Report (BGC 2014b) span 2010 through September 2013. Prior to mine dewatering, groundwater levels in the mine area were observed to follow topography, becoming deeper at higher elevations. Strong seasonal variations in groundwater levels were observed, particularly at higher elevations, indicating a snowmelt/precipitation-driven groundwater level hydrograph. Peak groundwater levels were observed in response to freshet and summer/fall storm events. Recharge beneath glaciers and in response to seasonal glacial melt was also identified as an unquantified contributor to groundwater recharge. Groundwater discharge zones are pervasive in the high-topography landscape, and include lakes, creeks, gullies, and seeps at breaks in slope.

Data collected since the beginning of mine construction in late 2015 have been summarized in Section 4 of stand-alone groundwater monitoring reports appended to and summarized within the *MA/EMA* Annual Reports. The 2021 annual groundwater monitoring report (Lorax, 2022b), which appears as Appendix 6.1-1 of Premium (2022a), has been included as Appendix 2-4 to this Application. Groundwater quantity is also summarized in the 4,950 tpd Groundwater Model Report (Appendix 5-1).

Recent (June 2021) groundwater levels are contoured in Figure 2.6-6. Continued dewatering of the VOK and WZ workings has created and sustained a marked cone of depression in the groundwater table in the footprint of the underground mine workings and farther afield. Water levels collected at wells near the VOK Zone suggest that drawdown at historic wells exceeds 100 m and that a groundwater divide exists between the VOK and WZ. The data recorded at higher elevation wells near the VOK indicates that seasonal water level fluctuations are on the order of tens of meters and hydraulic gradients at well pairs are moderately to strongly downward, reflecting depressurization of the groundwater system from depth. Groundwater flowpaths are towards the mine, with the exception of the area immediately downgradient of the CWP which is actively recharged by the pond. East of the WZ, water levels at selected well pairs are lower than the elevation of the WRTSF (1,364.5 masl) which suggests that the WRTSF is recharging groundwater at its outlet.

Groundwater inflows to the mine show significant seasonal variation with minimum flows in winter months ranging from 500 m^3/d to 750 m^3/d over the last several years of operations. Peak monthly flows during the open water season have ranged from 2,500 m^3/d to 3,000 m^3/d over the last two years, with peak daily flows on the order of 4,000 m^3/d on a couple of occasions during the 2021 freshet. Underground flows have remained within the WTP treatment capacity of 10,000 m^3/d and simulated monthly average flows show that underground flows are expected to remain below this threshold through operations. Treatment rates will be maximized at 10,000 m^3/d over a 15-month period at closure as described in the Closure Underground Water Quality Adaptive Management Plan (Appendix 9-2-2). This 15-month period includes seven months of mine flooding which will be accelerated using reclaim water from the WRTSF. The mine is predicted to flood to an equilibrium elevation of 1,404 masl on an average annual basis.

2.7 Water Quality

2.7.1 Surface Water Quality

A summary of surface water quality for the period 2014 to 2021 is provided below. Additional details of surface water quality information for the baseline period (i.e., prior to mine construction beginning in late 2015) and for the 2015 through 2021 period are provided as follows:

- Baseline surface water quality: Appendix 13-A of the 2014 EAC/EIS Application (Pretium 2014).
- 2015 through 2021 surface water quality data and information: MA/EMA Annual Report (Pretium 2016; 2017; 2018a; 2019; 2020a; 2021a and 2022a).

The Brucejack Mine surface water quality monitoring program is designed to generate data that will allow for the evaluation of mine-related effects on the aquatic receiving environment. This monitoring program is described in greater detail in Section 7.2.4. A summary of the sampling stations is provided below and a map of these stations is provided as Figure 2.7-1 and Figure 2.7-2.

Brucejack Mine site water quality monitoring stations required under PE-107835 (Appendix 1-1) are as follows:

- BJ 3.10 [Environmental Management System (EMS) # E298312] is located at the WRTSF outlet (56.4696, 130.1878, Figure 2.7-3) and is the final (most downstream) mine effluent discharge location;
- CC 0.87 (EMS # E298331) is located in Camp Creek 0.87 km upstream of the confluence with Brucejack Creek (56.4636, 130.1852, Figure 2.7-4);
- CC 0.01 (EMS # E298334) is located at the mouth of Camp Creek (56.4686, 130.1914, Figure 2.7-5);
- Mine Water Influent at WTP (EMS # E303052) is located in the WTP prior to treatment;
- CWP Influent at WTP (EMS # E303053) is located in the WTP prior to treatment;
- WTP Effluent (EMS # E302957) is located in the WTP after treatment and prior to WRTSF discharge;
- Tailings Supernatant (EMS # E302910) is located after thickening prior to outfall;
- Treated Domestic Effluent (EMS # E302911) is located after treatment prior to outfall; and
- CWP Direct Discharge to WRTSF (EMS # E306114) is located in the CWP or direct discharge line.

Aquatic receiving environment monitoring stations and the reference monitoring site required under PE-107835 and the Aquatic Effects Monitoring Plan (Appendix 9-1-4X) are as follows (Figure 2.7-6 and Figure 2.7-7):

- *BJ 2.62 (EMS # E298332) is located in Brucejack Creek upstream of VOK Creek and downstream of Camp Creek (56.4697, 130.1978, Figure 2.7-8);*
- *BJ 1.74 (EMS # E298333) is located in Brucejack Creek downstream of VOK Creek (56.4699, 130.2048, Figure 2.7-9);*
- *SC0 (EMS # E303050) is located in Sulphurets Creek approximately 3 km downstream of the sub-glacial confluence of Brucejack Creek with Sulphurets Creek, and approximately 6.5 km downstream of the WRTSF (56.4929, 130.2662, Figure 2.7-10);*
- *L3 OF (EMS # E303051) is located at a reference creek approximately 20 km northwest of the mine site at the outflow of L3 Lake (56.5703, 130.2662, Figure 2.7-11);*
- *T2 0.09 (AEMP monitoring station only) is located in Catear Creek which is a northern tributary to the WRTSF (56.4742, 130.1833, Figure 2.7-12); and*
- *KG 0.4 (AEMP monitoring station only) is located in the creek flowing from Knipple Glacier, upstream of the bridge (BJAR) (56.4038, 129.9826, Figure 2.7-13).*

Figure 2.7-13. KG 0.4 looking upstream (June 2022).

Surface water quality is monitored at the Brucejack Mine as required by Condition 4 and Appendix A of PE-107835 (Appendix 1-1), and in accordance with applicable Brucejack Mine management plans, including the Aquatic Effects Monitoring Plan (Appendix 9-1-4), ML/ARD Management Plan (Appendix 9-1-11), Chromium Management Plan (Appendix 9-2-1), and Nitrogen Management Plan (Appendix 9-2-6). Mine surface water quality monitoring is also a requirement of Condition D.4(d) of *Mines Act* Permit M-234 (Appendix 1-1).

BJ 3.10 is sampled weekly according to Condition 4 and Appendix A of PE-107835. Monitoring results are compared to discharge limits for BJ 3.10 specified in PE-107835 or BC Water Quality Guidelines (WQG) for the protection of freshwater aquatic life (FWAL) for parameters without discharge limits. Observed concentrations are evaluated using the trigger response plan presented in Section 5.9.

Monitoring of water quality in Brucejack Creek as presented in the *MA/EMA* Annual Reports has indicated mine related increases to concentrations of several parameters including hardness (Figure 2.7-14), nitrate (Figure 2.7-15), sulfate (Figure 2.7-16), antimony (Figure 2.7-17), and arsenic (Figure 2.7-18). BJ 3.10 water quality has been below current PE-107835 discharge limits during the 2015 through 2022 monitoring period except for short-duration TSS exceedances in October 2015 and in July 2022. The observed changes in water quality in Brucejack Creek are in line with the results of water quality modelling presented in the 3800 tpd Amendment Application for Permits M-243 and PE-107835 (Pretium 2022a). Refer to Section 5.5 and Appendix 5-3 for the updated water quality model that accounts for the increased ore production rate.

Figure 2.7-18. Total arsenic (As-T) measured in 2016-2021 compared to baseline.

2.7.1.1 Toxicity Testing

A summary of toxicity testing for the period 2014 to 2021 is provided below. Additional details of toxicity testing information for the baseline period (i.e., prior to mine construction beginning in late 2015) and for the 2015 through 2021 period are provided as follows:

- Baseline toxicity testing data: Appendix 14-A of the 2014 EAC/EIS Application (Pretium 2014).
- 2015 through 2021 toxicity testing data and information: *MA/EMA* Annual Report (Pretium 2016; 2017; 2018a; 2019; 2020a; 2021a and 2022a).
- Additional information on the toxicity testing monitoring program: Section 7.2.6.

Toxicity testing has and continues to be conducted as per PE-107835 and Metal and Diamond Mining Effluent Regulations (MDMER) requirements. PE-107835 currently requires that undiluted BJ 3.10 water not fail an acute lethality test using *Daphnia magna*, and not fail a growth inhibition test using a freshwater alga. PE-107835 also requires testing of survival and growth of the freshwater midge *Chironomus dilutus* in undiluted BJ 3.10 water, the results of which are interpreted in the annual reports but are not used for determining compliance with the permit. Toxicity testing of BJ 3.10 for PE-107385 is required quarterly. MDMER toxicity testing requirements have varied since Brucejack Mine became subject to MDMER on January 12, 2016. Currently, MDMER requires that undiluted BJ 3.10 be tested quarterly using the *Daphnia magna* acute lethality test, the rainbow trout acute lethality test, and the *Ceriodaphnia dubia* survival and reproduction test.

BJ 3.10 water has not failed any of the rainbow trout acute lethality tests conducted since testing for MDMER started in 2016. BJ 3.10 water has failed a Daphnia magna acute lethality test only once since testing began in 2015. During the construction phase, when toxicity testing was required monthly by PE-107835, a BJ 3.10 sample collected on December 20, 2015 failed the *D. magna* test. An investigation of cause was conducted but the investigation did not determine the cause. All subsequent *D. magna* tests have passed. BJ 3.10 water has passed all of the sublethal tests of growth using the freshwater alga *Pseudokirchneriella subcapitata* since testing of this species for PE-107835 began in 2016.

PE-107835 was amended in 2016 to remove the requirement for sublethal testing of BJ 3.10 water using *Ceriodaphnia dubia* and add the requirement to test BJ 3.10 water using the freshwater algal growth test. The algal growth test was added because arsenic had been identified as a parameter of potential concern, and algae are known to be sensitive to arsenic toxicity. The *C. dubia* test was removed because baseline testing, prior to the start of mine construction, found that BJ 3.10 water caused inhibition of reproduction in this species. Since *C. dubia* tests failed prior to mine construction, they could not be used to reliably indicate mine-related negative effects to water quality. While the requirement for *C. dubia* testing was removed from PE-107835, MDMER still required that *C. dubia* tests be conducted twice per year. Four of the six *C. dubia* tests conducted for MDMER between 2016 and 2018 had an inhibition of reproduction. In 2019, MDMER required the frequency of *C. dubia* testing to be changed to quarterly. There hasn't been an inhibition of *C. dubia* reproduction in any of the tests conducted after 2018. The cause of the change from BJ 3.10 water causing chronic toxicity to *C. dubia* during baseline and the early years of mine operation to not causing chronic toxicity after 2018 is uncertain but may be related to changes to BJ 3.10 water quality over time. For example, hardness of BJ 3.10 water increased in the first few years of operation (Figure 2.7-14) from well below the hardness recommended for culturing *C. dubia* (80-100 mg/L as $CaCO_3$; (Environment Canada 2007b)) to moderately below the recommended hardness.

Testing of survival and growth of the freshwater midge *Chironomus dilutus* in BJ 3.10 water began in February 2019 and is required quarterly. The purpose of the *Chironumus* tests are to identify long-term trends in toxicity. Statistical significance is determined relative to survival and growth in laboratory culture water. There was no statistically significant difference between survival in BJ 3.10 and laboratory water from in tests conducted from 2019 through 2021. Growth was statistically lower in BJ 3.10 water than in laboratory control water in February 2019 and in three of the four tests in 2021, while growth in other tests in 2019 and 2020 was not significantly different. While the more recent tests have had statistically significant differences, there has not been a noticeable long-term trend of increasing difference in biomass between individuals growing in laboratory control water and BJ 3.10 water (Pretium 2022a).

2.7.2 Groundwater Quality

Baseline groundwater quality is summarized in Section 7 of BGC (2014b) which comprised Appendix 9-A of the 2014 EAC/EIS Application (Pretium 2014) and is included as Appendix 2-3 to this Application. Groundwater samples are analyzed for physical parameters, anions and nutrients, and total and dissolved metals in accordance with PE-107835 requirements. Groundwater quality data presented in BGC (2014b) span 2011 through 2013. Data collected since the beginning of mine construction in late have been summarized in stand-alone groundwater monitoring reports appended to and summarized within the *MA/EMA* Annual Reports. Recent groundwater quality is summarized in Section 5 of the 2021 groundwater monitoring report (Appendix 2-4).

All Brucejack monitoring wells screen groundwater that is neutral to slightly alkaline (pH 7 to 8.5). Brucejack groundwater quality appears largely unimpacted by mining operations except for subtle shifts in major ion chemistry in wells dewatered by VOK development and isolated influences of surface infrastructure on shallower wells (such as seepage from the CWP). This is expected since groundwater flowpaths are largely towards the mine. There are limited instances where dissolved trace metals are measured above their background levels. Selected dissolved metals, such as arsenic appear to be naturally elevated in the groundwater system and are spatially variable across the site.

2.8 Sediment Quality

Baseline sediment quality are summarized in Section 14 of the 2014 EAC/EIS Application (Pretium 2014). Baseline sediment quality data span 2008 through 2013. Data collected in 2015 and 2016 are summarized in the 2015 and 2016 *MA/EMA* Annual Reports (Pretium 2016, 2017), and data collected each year starting in 2017 are summarized in stand-alone aquatics resources monitoring reports (ERM 2018a; 2018b; 2020; 2021; 2022) appended to and summarized within the *MA/EMA* Annual Reports (Pretium 2018a; 2019; 2020a; 2021a; 2022a).

PE-107835 requires sediment quality sampling annually at BJ 3.10 and BJ 2.62 during fall low flow conditions, and every three years at BJ 1.74, SC0, and L3 OF. Sediment samples are analyzed for particle size distribution, total organic carbon, pH, and metals in the <63 µm fraction.

Particle size distribution of sediment collected from Brucejack Creek sites varies from year to year and has not had a noticeable trend from baseline through 2021 (Figure 2.8-1). Particle size distribution at all sites was predominantly sand. Brucejack Creek sites had higher proportion of clay than SC0 in upper Sulphurets Creek or at reference site L3 OF. Particulate organic carbon content of sediment samples was low (<1%) at all sites and years sampled.

Figure 2.8-1. Sediment particle size distribution at sites in Brucejack Creek, Sulphurets Creek, and reference site L3 OF since 2011 (Figure 5.2-1 of ERM (2022)).

British Columbia has working sediment quality guidelines (WSQGs) for several metals. These guidelines are defined as:

- Lower WSQG – a concentration that will protect aquatic life from adverse effects of toxic substance in most situations. Equal to the CCME interim sediment quality guideline for many metals.
- Upper WSQG – a concentration that if exceeded will likely cause severe effects to aquatic life. Equal to the CCME probable effects level for many metals.

Several metals have consistently had higher concentrations in sediment samples collected from lower Brucejack Creek (BJ 2.62 and BJ 1.74) than upper Brucejack Creek (BJ 3.10). BJ 2.62 is downstream of Camp Creek, and BJ 1.74 is downstream VOK Creek, both of which are seasonally acidic tributaries traversing the gossan to the south and east of Brucejack Creek, and do not receive mine contact water. The higher downstream concentrations of arsenic (Figure 2.8-2), cadmium (Figure 2.8-3), copper (Figure 2.8-4), lead (Figure 2.8-5), selenium (Figure 2.8-6), silver (Figure 2.8-7), and zinc (Figure 2.8-8) may reflect inputs from these seasonally acid streams. Mercury (Figure 2.8-9) is an

exception to the trend of increasing concentration with distance downstream in Brucejack Creek. Mercury concentrations at BJ 3.10 have consistently been greater than the Upper WSQG while concentrations at BJ 2.62 and BJ 1.74 have been between the lower and upper WSQGs. Mercury concentration at BJ 3.10 has not increased over time; therefore, it is unlikely that the higher concentrations measured at BJ 3.10 are related to mine inputs. Other metals have a similar pattern as mercury of being enriched in Brucejack Creek samples relative to the lower WSQG but not having a marked change in concentration after mine construction began in 2015 compared to baseline (Figure 2.8-2 through Figure 2.8-8).

Notes: Error bars represent the standard error of the mean.
Values below the detection limit were plotted as half the detection limit.
CCME sediment quality guideline: PEL = probable effect level; ISQG = interim sediment quality guideline.
Metals in 2017 were mistakenly analyzed on the <2 mm size fraction for BJ 3.10, BJ 2.62, and BJ 1.74. Results have been excluded from the graphs.

Figure 2.8-9. Mercury concentration in the <63 µm fraction of sediment samples collected at sites in Brucejack Creek, Sulphurets Creek, and reference site L3 OF since 2011 (Figure 5.2-6 of ERM (2022)).

2.9 Fisheries and Aquatic Resources

2.9.1 Periphyton and Benthic Invertebrate Community Measures

PE-107835 requires periphyton and benthic invertebrate monitoring annually at BJ 3.10, BJ 2.62 and BJ 1.74, and every three years at SC0 and L3 OF. Periphyton and benthic invertebrates are sampled in August annually, during low flow conditions. Periphyton biomass and taxonomy are measured as indicators of periphyton community characteristics at each station. Benthic invertebrates are sampled using a kick net following the Canadian Aquatic Biomonitoring Network (CABIN) protocol by CABIN-certified field personnel. Benthic invertebrate community characteristics are compared to reference station characteristics.

All periphyton biomass samples collected from Brucejack Creek during the 2015 through 2019 survey period were below the BC WQG of 10 µg/cm2 chlorophyll-a. There was high variability among replicates at each of the Brucejack Creek sites and high interannual variability. Brucejack Creek periphyton biomass and density increased moving downstream in 2021, with communities dominated by Cyanophyceae (blue-green algae), and Bacillariophyceae (diatoms). Both were dominant at BJ 2.62, with Bacillariophyceae largely represented by the genus *Achnanthidium* and Cyanophyceae by the genus *Calothrix*. At BJ 3.10, Cyanophyceae was represented by the genera *Pseudanabaena* and *Merismopedia*; and Chrysophyceae largely by the genus *Hydrurus*. Biomass and density in Brucejack Creek were generally elevated in 2021 compared to the historical range, in addition to increases in genus richness and diversity. Communities at BJ 3.10 have become increasingly diverse over the past two years after reaching low diversity in 2019. By contrast, richness and diversity have increased above the historical range over the past several years at BJ 2.62, largely attributable to more Cyanophyceae and Bacillariophyceae genera.

Benthic invertebrate community samples collected from Brucejack Creek during the 2015 through 2019 survey period exhibited large variability between stations and between years. There was also large year to year variability at reference site L3 OF. No relationship could be discerned between mine effects on water quality and benthic invertebrate communities over the five-year survey period. Benthic invertebrate abundance increased in Brucejack Creek moving downstream in 2021, dominated upstream by Diptera (true flies) and downstream by Plecoptera (stoneflies). Brucejack Creek in recent years has been dominated by Plecoptera, particularly the genus *Zapada* (family Nemouridae), representing a major shift in community composition. In 2021, however, upstream sites BJ 3.10 and BJ 2.62 returned to a historical composition with decreases in Plecoptera. Abundance was within the historical range at all sites. Family richness increased downstream and was within the historical range at upstream sites. Downstream at BJ1.74, richness was above the historical range yet had the lowest family diversity due to continuing dominance by Plecoptera (*Zapada*). Benthic invertebrate communities were compared to the Canadian Aquatic Biomonitoring Network (CABIN) BC central/north coast reference model. In 2021, benthic invertebrate communities at all three Brucejack Creek sites were classified as “Mildly Divergent” from the CABIN reference communities, having been classified as either “Mildly Divergent” or “Divergent” during baseline.

The interannual differences in periphyton biomass and community composition, and benthic invertebrate abundance and community composition over the monitoring period, which has included baseline, construction, and operation phases of the mine, appear unrelated to mining activities and can most likely be attributed to natural variability.

2.9.2 Fish and Fish Habitat

As described above in Section 2.5, the Brucejack Creek watershed is a small headwater sub-basin within the Sulphurets Creek watershed (drainage area 299 km^2). Brucejack Creek drains into Sulphurets Creek before reaching the Unuk River (Figure 1.4-3), which flows southwest, eventually discharging to the Pacific Ocean northeast of Ketchikan, Alaska.

Fish sampling programs in 2013 confirmed no fish presence in Brucejack Lake, Brucejack Creek, and Sulphurets Creek above a 200 m long cascade located approximately 1.3 km upstream of the Unuk River confluence (Rescan 2013g). Sampling was conducted immediately upstream of this barrier, in several large tributaries of Sulphurets Creek and in Brucejack Lake. Sampling effort above the cascade included 3,000 seconds of electrofishing sampling and 913 hours of minnow trapping. Therefore, the closest fish-bearing waters are more than 20 km downstream of the effluent discharge (refer to Figure 1.4-3).

Fisheries sampling conducted in 2013 (regional study area) included fish habitat surveys, and community surveys in streams (via electrofisher) and lakes (via minnow traps and gill nets). Biological characteristics of caught fish were recorded (i.e., species, weight, fecundity), and fish were sampled for genetics, tissue metals, and diet. Details of the fisheries program are available in the baseline report (Rescan 2013g).

The Unuk River within the region supports populations of Chinook Salmon (*Oncorhynchus tshawytscha*), Coho Salmon (*Oncorhynchus kisutch*), and Dolly Varden (*Salvelinus malma*), with historical data indicating the presence of Sockeye Salmon (*Oncorhynchus nerka*), Rainbow Trout (*Oncorhynchus mykiss*), Chum Salmon (*Oncorhynchus keta*), Pink Salmon (*Oncorhynchus gorbuscha*), and Cutthroat Trout (*Oncorhynchus clarkia*).

2.9.3 Tissue Residues

Fish tissues were collected in 2013 in the Unuk River downstream of the Sulphurets Creek confluence (Rescan 2013g). Unuk River Dolly Varden (eight samples) mean concentrations were 0.021 mg/kg wet weight for mercury, and 3.9 mg/kg dry weight for selenium. Coho Salmon (11 samples) mean concentrations were 0.020 mg/kg wet weight for mercury and 3.0 mg/kg dry weight for selenium. Baseline fish tissue concentrations were below the CCME tissue methylmercury guideline (0.033 mg/kg wet weight, assuming 100% of the total mercury in fish tissue was present as methylmercury) and the ENV selenium guideline for fish tissues (4 mg/kg dry weight).

3. MINE PLAN

3.1 Mine Plan Overview

As described in Chapter 1, Pretium Resources Inc., a member of the Newcrest Group of companies, is applying to increase the Brucejack Mine ore production rate authorized under *Mines Act* Permit M-243 from an annual average of 1.387 Mt to 1.807 Mt (equivalent to an increase from an average 3800 tpd to 4950 tpd). The 4950 tpd mine plan presented in this 4950 tpd Joint Application has been updated based on the mine plan presented in the 2019 National Instrument 43-101 Technical Report dated March 9th, 2020 (Tetra Tech 2020). The production rate increase from 3800 tpd to 4950 tpd would result in a shortened mine life from the 16 years spanning 2017 through 2032 presented in the 2020 mine plan, to 13 years spanning 2017 through 2029.

The Brucejack Mine produces gold and silver from the VOK and WZ deposits. The vertical and horizontal extents of the underground mine development for the 4950 tpd Joint Application mine plan remain similar to those presented in the 3800 tpd Amendment Application as per Permits M-243 and PE-107835 (Pretium 2018b) and the 2020 Mine Plan and Reclamation Program Update (Pretium 2020b). Mine plan changes in the 4950 tpd Joint Application compared to these previous submissions include updates to a subsection of the VOK called the North Block, and additional underground exploration development to the east, west and south.

Small portions of the updated exploration development extend beyond the current M-243 PMA boundary (Figure 3.2-1). In September 2022, Pretium submitted an M-243 permit amendment application to extend the mine's current PMA to the existing mining lease boundaries (M-243 Amendment #9). If approved, the exploration development currently outside of the PMA will be contained within it.

All waste rock at the mine is managed as PAG and is either deposited subaqueously at the mine's WRD within the WRTSF or backfilled in mined out areas of the underground mine below the predicted closure flooding elevation. Mine tailings are co-mingled with sludge from the mine's WTP and deposited subaqueously in the WRTSF. Total Life-of-Mine (LOM) waste rock deposition to the WRTSF remains within the 7.8 Mt currently authorized under M-243, and total tailings deposition to the WRTSF remains below the authorized 11.9 Mt. Total ore production does not exceed the 18.5 Mt authorized under EAC M#15-01.

The underground mine has been designed to extract ore through a combination of transverse long hole open stoping (LHOS) and longitudinal LHOS in a traditional primary/secondary sequence. Primary stopes are backfilled with cemented paste tailings and secondary stopes are backfilled with cemented paste tailings or waste rock. The mine utilizes a combination of conventional bulk sulphide flotation and gravity concentration to produce gold-silver floatation concentrate and doré from the on-site smelter. Both products are transported offsite for additional processing and refinement.

The increased mining rate from 3800 tpd to 4950 tpd will be sustained by expanding the battery electric vehicle (BEV) fleet and increased rates of drilling and development. No changes from the mining methods presented in the 2020 Mine Plan and Reclamation Program Update (Pretium 2020b) are required to achieve the production increase. Unrelated to the proposed production rate increase, Pretium is continuing to expand the Brucejack Mine battery electric vehicle fleet.

The following infrastructure upgrades and equipment changes have been identified to facilitate the production increase from 3800 tpd to 4950 tpd:

- Increasing the haul truck fleet size from eight to 11 (at minimum) 50 t BEVs and addition of an electric load-haul-dump (LHD) vehicle (Section 3.5.1.7);
- Additional Knelson concentrator within the mill, and upgrades to the gravity and floatation circuits (Sections 3.5.2.3.3 and 3.5.2.3.4);
- A fourth C75 domestic wastewater treatment unit (Section 3.5.4.6)
- Increasing the mine's power supply delivered by the existing 138 kV and 69 kV lines to 35 MVA, for which both lines are adequately rated (Section 3.5.7); and,
- Additional underground emulsion bay (Section 3.5.8.2).
- While no additional infrastructure is required to manage waste rock associated with a 4950 tpd production increase, Pretium is evaluating the development of a second waste rock dump (East WRD), temporary waste rock stockpile(s) (WP2) and supporting haul road east of the WRTSF. The potential upgrades to the existing waste rock management infrastructure are intended to improve the mine's waste rock management strategy, irrespective of the production rate increase. Therefore, the EWRD and WP2 stockpile(s) are contingency management options only. Should Pretium decide to advance development of this infrastructure, the required authorizations will to be pursued through separate authorization processes, outside of this amendment application.
- Similarly, a fifth vent raise (VR5) (Section 3.5.1.8) and four new tailings discharge lines to the WRTSF are being considered for installation between 2023 and 2026, regardless of production rate (Section 3.5.3.4 and Appendix 3-1). The new tailings lines are intended to replace existing and future tailings lines through LOM.

3.2 Existing Development

3.2.1 Mines Act Permit M-243 Authorized Infrastructure

Mines Act Permit M-243 authorizes infrastructure within Pretium's mining leases and the northernmost 19.5 km of the mine's 57 km-long high voltage transmission line connecting the mine to the BC Hydro grid near the Long Lake generating station (LNL) facility (Figure 3.2-1).

The following facilities are located within the mine site area as of January 2023 (Figure 3.2-1 and Figure 1.4-2):

- Four underground vent air raises.
- VOK and WZ underground mine portals.
- WZ pad, within which surface support infrastructure for the underground mine is located. This includes the old heavy shop, staging areas for waste rock, offices, covered storage, propane storage for mine air heater, and fuel storage and dispensing stations.
- Diesel power station (DPS) pad, including diesel generators and fuel storage serving as a back-up electrical generation facility.

- Mill building housing ore processing equipment, smelting furnace, WTP, paste backfill plant, assay laboratory, core processing area and related facilities.
- Lower and upper camps with kitchen, recreation, laundry, mine and mill dry facilities, medical clinic, fire hall, administration/offices, potable water well distribution and treatment system, STP, and solid waste management systems.
- Surface heavy duty shop to service surface vehicles and mobile equipment.
- Cement binder storage silo for pasting operations.
- Avalanche cap and powder magazines.
- Warehouse, coverall storage and equipment laydown areas.
- Heli-pad.
- Solid waste sorting and handling facilities, incinerator, waste oil burners, and burn pits.
- Contact and non-contact water management facilities, including mine dewatering, freshwater diversion channels, surface contact water collection system and a contact water storage pond (CWP).
- Overburden stockpile.
- The WRTSF containing five subaqueous tailings discharge pipelines, a treated WTP/STP effluent discharge pipeline, an emergency discharge pipeline from the CWP, and the WRD platform and associated temporary waste rock stockpile (WP1) that facilitates subaqueous waste rock deposition.
- A low-level weir (LLW) at the WRTSF outlet (site BJ 3.10) housing flow monitoring instrumentation and water reclaim equipment. The LLW facilitates continuous from the WRTSF to Brucejack Creek and houses a reclaim water pumping system that provides fresh water for to the mill.
- NPAG quarry (km 72 NPAG quarry) that provides NPAG material for surface and underground mine development and road maintenance.
- Site roads to connect mine area facilities, including the BJAR section between the km 72 NPAG quarry and the mine site.
- Communication, monitoring, and control systems, including wireless local area network receivers, underground fiber optic network, radio base stations, programmable logic controllers, and video cameras.

A new heavy-duty shop (truck shop) housing equipment and vehicle repair, washbays, and a warehouse will replace the existing shop and warehouse in 2023. Additional authorized surface infrastructure for which construction not yet initiated includes gravel borrow sources at the east end of the WRTSF, and future realignments of the upper BJAR ramp onto Knipple Glacier near BJAR km 72.

The M-243 approved surface disturbance area for the mine is 659.3 ha. This approved disturbance is categorized into disturbance types as per BC Ministry of Energy, Mines and Low Carbon Innovation (EMLI) guidance for reclamation reporting. The approved disturbance types include structures and their immediate surroundings: plant site (38 ha), roads (11 ha), lower and upper camps (5 ha), CWP

(0.7 ha), overburden stockpile (0.4 ha), seepage ponds (0.02 ha), transmission line (66 ha), historical exploration (66 ha), and WRTSF & NPAG quarry (90 ha) totaling 278 ha of actual disturbance.

3.2.2 Transmission Line

The Brucejack high voltage transmission line extends southeast from the mine site to a substation at Pretium's Knipple camp in the Bowser River Valley, and then south to a tap point on the 138 kV line between the Stewart substation (LNT) and LNL terminal generating station. Much of the 57 km transmission line is authorized under Statutory Right-of Way (ROW) #6408729. The boundary between the ROW and M-243 authorized portions of the transmission line is located approximately 5 km south of the Knipple transfer area at approximately km 37.1 of the transmission line. The transmission line segment authorized under ROW #6408729 is not described further in this amendment application.

Imagery: 2022 Lidar | Date: March 10, 2023

Figure 3.2-1 Mine Site General Arrangement and Detailed Infrastructure Plan - End of 2022

3.2.3 Waste Rock and Tailings Storage Facility

Brucejack Mine tailings and waste rock are subaqueously deposited into the WRTSF, and treated mine effluents (mine and wastewater from the WTP and STP respectively) are also discharged into this facility. Non-contact water runoff reports to the WRTSF from the facility perimeter and east non-contact water diversion channel (Johnson Creek). Contact water from the mine site is collected within the mine's contact water management system, and reports to the WTP before discharge. The WRTSF outlet, the LLW at BJ-3.10 (Section 3.5.4.5), allows for unobstructed outflow from the facility (no impoundment infrastructure), and serves as the mine's final effluent discharge point to Brucejack Creek.

Additional information, including descriptions of the site terrain, hydrogeological conditions, natural hazards, monitoring and emergency response are provided in the WRTSF – Operations, Maintenance and Surveillance (OMS) Manual (Appendix 9-1-17).

3.2.3.1 Tailings Storage

Brucejack Mine Tailings are classified as NPAG and are discharged to the WRTSF via pipelines for subaqueous storage. The discharge outfalls are located within 7.5 m off the tailings surface in accordance with PE-107835 Condition 1.3.2. Tailings Lines 1 and 2 are suspended in the WRTSF using an engineered cable system. Tailings Line 3 was installed in 2017 and Tailings Line 5 and 6 were both installed in 2021 and are anchored to the bottom of the WRTSF (Figure 3.2-1).

Prior to the commencement of tailings deposition in May 2017, the WRTSF had a maximum depth of approximately 85 m and a total volume of approximately 28.5 Mm^3. The 2018 3800 tpd Amendment Application for Permits M-243 and PE-107835 (Pretium 2018b) authorizes deposition of up to 11.9 Mt of tailings subaqueously in the WRTSF, with the remainder to be deposited as paste (consisting of thickened tailings and cement binder) backfill in the underground mine. The WRTSF storage capacity remains more than sufficient for placement of all tailings and waste rock requiring subaqueous deposition during the proposed 13-year mine life (Appendix 3-1).

The proposed 4950 tpd mine plan presented in this Joint Amendment Application allows for 11.3 Mt of tailings to be deposited into the WRTSF. Therefore, the proposed production increase to 4950 tpd does not result in an increase to the authorized total tailings deposition (11.9 Mt) to the WRTSF.

The 4950 tpd LOM tailings deposition plan is presented in Appendix 3-1. The mine's waste rock and tailings management operational procedures are described in the WRTSF – Operations, Maintenance and Surveillance (OMS) Manual (Appendix 9-1-17).

3.2.3.2 Waste Rock Storage

Most surface waste rock and all underground waste rock at the mine is managed as PAG, in accordance with M-243 Condition D.3. Waste rock is either deposited subaqueously within the WRTSF from the WRD or backfilled in the underground mine below the ultimate closure flooding elevation. The WRD and associated temporary waste rock stockpile (WP1) are located on the southern shore of the WRTSF near the outlet (Figure 3.2-1). Waste rock deposition into the WRTSF has been by remote operated dozer push since May 2021. Previous deposition methods included conventional dozer, telestacker and excavator bailing methods. These alternative deposition methods remain authorized and may be used again in future.

The 2018 3800 tpd Amendment Application for Permits M-243 and PE-107835 (Pretium 2018b) authorized subaqueous deposition of up to 7.8 Mt of surface and underground waste rock in the WRTSF, with the remainder to be backfilled in the underground mine. The 4950 tpd mine plan presented in this Joint Amendment Application allows for 6.4 Mt of underground waste rock to be deposited into the WRTSF. Therefore, total waste rock deposition to the WRTSF resulting from the proposed production increase is similar to the tonnage authorized in 2018.

The 4950 tpd LOM waste rock deposition plan is presented in Appendix 3-1-1, and incorporates the EWRD and associated WP2 stockpile(s) to demonstrate deposition with this contingency in place. Waste rock deposition at 4950 tpd without incorporating the EWRD is discussed in Section 3.5.3. The mine's operational procedures are described in the WRTSF – OMS Manual (Appendix 9-1-17). An updated geotechnical assessment that includes a summary of the subsurface conditions, design criteria, slope stability analyses, seismic hazard classification, and instrument monitoring recommendations for the WP1 temporary waste rock stockpile is provided in Appendix 3-2.

3.2.4 Underground Mine

Access and egress to the mine, including the transportation of waste rock out of the mine, is provided at the WZ portal and the VOK portal (Figure 3.2-1). A fleet of modern, diesel and battery powered, rubber-tired LHDs and trucks are used for ore and waste loading and transport from underground working areas through an internal ramp system that connects all levels to a centrally located crusher. Waste rock is primarily transferred from underground mine via the WZ portal and transported by haul truck to the WRD. Crushed ore is transferred from the underground mine to the mill concentrator/processing plant by conveyor via the VOK decline and VOK portal.

Permanent fans provide ventilation by forcing air down the declines, through the internal ramps, and exhausting to surface via four dedicated exhaust raises that connect the working levels to surface. The primary fans are located at each of the WZ and VOK portals. An electric mine air heating system is used, with a propane system available as a backup for supplemental heating.

Major underground infrastructure includes the primary jaw crusher, conveyors, ventilation raises, fans, heating system, pumping stations, electrical substations, explosives magazines, paste fill booster pump station, refuges, underground batch plant, mine communications, and other ancillary installations.

3.3 Life of Mine Plan

3.3.1 Mine Plan Summary

The 4950 tpd mine plan presented in this 4950 tpd Joint Application has a total LOM of 13 years spanning 2017 through 2029. Mining production is currently focused on the VOK zone (comprising the Main VOK, Fault Zone and North Block), with production also including the WZ beginning in 2025. The proportion of material mined in the WZ relative to the VOK will increase from 2025 over the remainder of mine life.

Initial development focus is on the VOK lower and middle blocks, with expansion into the Fault Zone area of the VOK. The Main VOK section is divided into four mining horizons separated by sill levels located at 960, 1080, 1200, and 1320 masl. Mining and development will progress over time, expanding out from the middle mining horizons.

The following development will occur in parallel with the VOK middle block development and mining:

- Advancement of the VOK decline to the 960 Level;
- Advancement of the VOK incline to the 1530 Level; and
- Development towards additional mining horizons such as the Fault Zone, North Block and WZ.

Development of the VOK ramp will advance continuously to the extents of the mine. Levels will continue to be developed and stoping will continue within the VOK and WZ deposits to a maximum of 18.5 Mt of total ore production (Table 3.3-1). Development of the WZ ramp is currently underway to allow production from the lower WZ blocks by 2025. Mining of the WZ deposit will begin in 2024/2025 but full production from this area does not begin until 2027. During this period of mine life, development requirements will decrease.

The 5th surface vent raise is planned to be completed by 2025. Internal raises will be developed within the mine as determined by scheduling requirements.

Figure 3.3-1 and Figure 3.3-2 are 3-dimensional views of the mine at EOM, showing mine development and the main stoping areas by year based on the 4950 tpd mine plan. Waste rock dump development, tailings deposition and km 72 NPAG quarry seasonal operations will continue until the mine closure period (2029-2031). No additional surface infrastructure related to the underground mine is planned for the period from 2025 to mine closure. Figure 3.3-3 shows the mine site area plan at EOM, with the horizontal extents of the mine.

As described in Section 3.1, the M-243 Amendment #9 application currently under review includes additional PMA that would address the boundaries authorization aspect of proposed exploration development in this amendment application that extends beyond the current PMA boundaries. Closure and reclamation planning is discussed in Chapter 4 and Appendix 4-1 of this 4950 tpd Joint Application.

Table 3.3-1. Projected Ore Schedule.

Year	Total Ore (kt)
2017	684
2018	952
2019	1,338
2020	1,252
2021	1,415
2022[1]	1,387
2023	1,418
2024	1,711
2025	1,807
2026	1,807
2027	1,807
2028	1,706
2029	1,213
Total	**18,498**

1. Planned ore schedule as per 4950 tpd mine plan starting in 2022.

Figure 3.3-3. Mine Site Area Plan, End of Mine (EOM)

3.3.2 Mine Waste Materials

3.3.2.1 Mine Waste Rock Inventory

All underground waste rock is managed as PAG and either deposited subaqueously in the WRTSF or backfilled in the underground mine below the predicted flooding elevation. As backfill, waste rock is placed either as a bulk fill in remote stopes or placed with paste tailings in secondary stopes. The 4950 tpd mine plan is expected to produce approximately 8.0 Mt of underground and surface waste rock over the entire LOM (i.e., from start of construction in 2015 through EOM in 2029). Approximately 1.6 Mt of the total waste rock tonnes generated will be used as backfill. The total quantity of underground waste rock reporting to the WRTSF is similar to the total tonnage authorized in 2018.

Beginning in 2022, the percentage of waste rock used as underground mine backfill increases to approximately 40%, due to reductions in the total quantity of waste generated, as opposed to a higher percentage of waste rock fill stopes. The 1.6 Mt of waste rock fill over LOM accounts for approximately 13% of the total volumetric fill for the underground mine, with the remaining void volume filled with paste. Table 3.3-2 lists the annual waste rock inventory from 2015 to 2029 based on the 4950 tpd mine plan.

Table 3.3-2. Underground Waste Rock Inventory (2015-2029)

Year	Underground Total Waste Tonnes (kt)	Underground Waste Fill (kt)	Underground Waste to WRTSF (kt)
2015	98	-	98
2016	712	-	712
2017	484	-	484
2018	728	28	700
2019	788	22	766
2020	915	66	849
2021	894	102	792
2022[1]	809	231	578
2023	812	241	571
2024	803	173	630
2025	408	225	183
2026	253	220	33
2027	191	172	19
2028	62	59	3
2029	59	57	2
Total	**8,016**	**1,596**	**6,420**

1. Planned waste rock inventory as per 4950 tpd mine plan starting in 2022.

3.3.2.2 Tailings Inventory

Tailings generated during milling are either discharged subaqueously into the WRTSF or placed underground as cemented paste backfill. Table 3.3-3 presents the actual tailings deposition up to 2021, and the planned tailings deposition schedule starting in 2022. A total of 11.2 Mt of tailings reports to the WRTSF over LOM in this 4950 tpd mine plan. Tailings sent underground account for 87% of the total backfill volume required over LOM. The total quantity of tailings reporting to the WRTSF is similar to the total tonnage authorized in 2018.

Table 3.3-3. Tailings Inventory (2017-2029)

Year	Total Tailings (kt)	Tailings Underground (kt)	Tailings to WRTSF (kt)
2017	628	105	523
2018	1,006	411	595
2019	1,303	480	823
2020	1,307	474	833
2021	1,383	409	974
2022[1]	1,317	467	850
2023	1,346	521	826

2026	1,715	572	1,144
2027	1,715	592	1,123
2028	1,619	679	940
2029	1,152	760	391
Total	**17,832**	**6,590**	**11,242**

2. Planned tailings inventory as per 4950 tpd mine plan starting in 2022.

3.3.2.3 Underground Backfill Inventory

Table 3.3-4 tabulates the projected tonnages of waste to be generated from milled ore and development headings, and the destination of these materials over time. Over the total LOM, approximately 20% of waste tonnes and 37% of tailings generated from milled ore is placed back underground. The remaining balance is disposed of subaqueously in the WRTSF.

Table 3.3-4. LOM Backfill Inventory - Waste Rock and Tailings

Year	Total Tailings (kt)	Paste Fill Tonnes (kt)	Tailings to Surface (kt)	Underground Waste Tonnes (kt)	Underground Waste Fill Tonnes (kt)	Underground Waste to Surface (kt)
2015	-	-	-	98	-	98
2016	-	-	-	712	-	712
2017	628	105	523	484	-	484

3. Planned backfill inventory as per 4950 tpd mine plan starting in 2022.

3.4 Detailed Five Year Mine Plan

3.4.1 Introduction

The Brucejack Mine has two main zones of mining: the VOK and the West Zone. The VOK is further divided into three subzones: the Main VOK, the Fault Zone, and the VOK North Block. Levels within the Brucejack Mine are identified in meters above sea level (masl) according to mucking elevation. There are four main sill levels where stoping panels are initiated and stopes proceed vertically upward to the next sill level above. The sills are located at 960, 1080, 1200, and 1320 masl in the VOK zone, which is currently the primary source of ore until 2027 when stoping in the WZ increases.

3.4.2 2022

Most mining during 2022 was completed between the VOK 1050 and 1440 Levels, with minor production outside these levels. Mining occurred primarily in the Main VOK deposit with the Fault Zone as the secondary source. Initial development was completed for the VOK North Block to allow for additional drilling and exploration. The VOK ramp reached the 990 Level and initial level development was initiated. Development will continue within established levels to allow for future mining sequences.

The WZ decline continued to be developed with priority on establishing the development to access VR5. Development of internal raises for escapeways and ventilation began in the West Zone.

A 3-dimensional view of the underground mine at the end of 2022 is shown as Figure 3.4-1. The horizontal extent of the underground mine at end of 2022 is shown as Figure 3.3-2.

Construction of the new surface truck shop was initiated in 2022 (Figure 3.4-2). WRTSF tailings deposition and WRD operations continued along with seasonal operations at the km 72 NPAG quarry to source NPAG rock for underground and road surfacing and other operational purposes as needed.

Figure 3.4-1. Three-dimensional Underground Mine View - End of 2022.

Figure 3.4-2. Mine Site Area Plan, End of 2022

3.4.3 2023

During 2023, mining focus will split relatively evenly between the Main VOK and the Fault Zone. Initial mining of the VOK North Block will begin but remain a minor contributor to the mill feed. The lower levels, 960-1050 masl, will begin to be mined at an increased rate.

In addition to development at the lower levels, level development will begin above the 1440 Level to target targeting upper VOK reserves. The WZ decline will continue to be developed with priority on establishing access to VR5. Internal raises for manways and ventilation will continue to be developed in the WZ. A 3-dimensional view of the underground mine at the end of 2023 is shown as Figure 3.4-3; the horizontal extent of the underground mine is shown on Figure 3.4-4.

Construction of the new truck shop will be completed in 2023 (Figure 3.4-4). Additional tailings management infrastructure to be installed in 2023 will include two new tailings discharge lines. Pending separate authorizations outside of this 4950 tpd amendment application, an access road will be constructed at the east end of the WRTSF to facilitate development of the EWRD and WP2 stockpiles, should Pretium determine to pursue development and authorization of this contingency infrastructure. WRTSF tailings deposition and WRD operations will continue as per the deposition plan (Appendix 3-1), along with seasonal operations of the km 72 NPAG quarry.

Figure 3.4-3. Three-Dimensional Underground Mine View - End of 2023.

Figure 3.4-4. Mine Site Area Plan, End of 2023

3.4.4 2024

Production of the Main VOK is expected to be mostly complete between the 1200 and 1440 levels in 2024, with production primarily coming from the 990 to 1170 levels and levels above 1440. Mining will also continue in the Fault Zone. The VOK North Block will continue to be established and mined at a lower rate than the Main VOK and Fault Zone. Standalone West Zone stopes will begin to be mined ahead of VR5's completion. Ramp up to average 4950 tpd is expected to be achieved by the second quarter of 2024.

VOK ramp development will have been completed, with the primary focus for development shifted to the Fault Zone and VOK North Block portions of the VOK, and to the West Zone. The WZ development is expected to reach VR5 and preparation for the vertical development of this raise is planned to begin. A 3-dimensional view of the underground mine at the end of 2024 is shown as Figure 3.4-5. The horizontal extent of the underground mine at the end of 2024 is shown on Figure 3.4-6.

During 2024, construction of surface infrastructure commenced in 2023 will be completed (Figure 3.4-6). Tailings to the WRTSF and waste rock deposition at WP1 will continue. Pending separate authorization outside of this 4950 tpd amendment application, and if Pretium pursues development of contingency waste rock management infrastructure, the East WRD will be established using waste rock material temporarily stored in WP2, as per the waste rock and tailings deposition plan (Appendix 3-1). WRTSF tailings deposition and operations at both waste dump locations will continue, along with seasonal operations of the km 72 NPAG quarry.

Figure 3.4-5. Three-Dimensional Underground Mine View - End of 2024.

Figure 3.4-6. Mine Site Area Plan, End of 2024

3.4.5 2025

Primary stope production during 2025 is expected to be from the lower VOK levels and the Fault Zone with the VOK North Block continuing to provide secondary feed and level development. Completion of the return air raise of the WZ (VR5) is expected with further development of the WZ ramp and levels to set up for mining. Mining in the West Zone is still minor but most infrastructure is now established. A 3-dimensional view of the underground mine at the end of 2025 is shown as Figure 3.4-7; a horizontal view showing the maximum horizontal extents is shown on Figure 3.4-8.

WRTSF tailings deposition and WRD operations will continue, along with seasonal operations at the km 72 NPAG quarry. Contingent on Pretium's decision to pursue additional authorization for the EWRD and WP2 stockpiles, and as described in the waste rock and tailings deposition plan (Appendix 3-1), waste rock deposition from WP2 to the East WRD is scheduled for completion, with WP2 and the EWRD remaining available for contingency use.

Figure 3.4-7. Three-Dimensional Underground Mine View - End of 2025.

Figure 3.4-8. Mine Site Area Plan, End of 2025

3.4.6 2026

The production profile from 2025 will continue during 2026, with focus on the upper and lower VOK areas. The Main VOK and Fault Zone are evenly split in terms of production weight, with the VOK North Block providing minor supplement to the feed. The WZ will begin to ramp up production following the completion of VR5. The WZ development will be focused on establishing the lower mining horizons and WZ ramp development will reach the 1040 Level. The VOK North Block level development will be mostly complete by 2024, with future development focusing primarily on crosscut development.

WRTSF tailings deposition and WRD operations will continue, along with seasonal operations at the km 72 NPAG quarry.

A 3-dimensional view of the underground mine at the end of 2026 is shown as Figure 3.4-9; a horizontal view showing the maximum horizontal extent is shown on Figure 3.4-10.

Figure 3.4-9. Three-dimensional Underground Mine View – End of 2026.

Figure 3.4-10. Mine Site Area Plan, End of 2026

3.4.7 2027

West Zone stoping will become a major contributor to the mine plan in 2027. The VOK North Block will also increase in proportion to compensate for the decrease in material being mined from the Main VOK. Development will be primarily focused in the WZ, with focus on crosscut development. A 3-dimensional view of the underground mine at the end of 2027 is shown as Figure 3.4-11; a horizontal view showing the maximum horizontal extent is shown on Figure 3.4-12.

WRTSF tailings deposition and WRD operations will continue, along with seasonal operations at the km 72 NPAG quarry.

Figure 3.4-11. Three-dimensional Underground Mine View – End of 2027.

Figure 3.4-12. Mine Site Area Plan, End of 2027

3.5 Mine Facility Designs and Development

3.5.1 Underground Workings

3.5.1.1 Overview

The proposed mine plan is designed to extract average 4,950 tpd of ore through a combination of transverse LHOS and longitudinal LHOS mining methods. A fleet of diesel and electric LHDs and trucks is used for material loading and transport from the various underground working areas through an internal ramp system that connects all mine levels to the centrally located crusher.

Permanent fans provide ventilation by forcing air down the declines, through the internal ramps, eventually exhausting to surface via dedicated raises that connect the working levels to surface in each zone. The primary fans are located at each of the two surface portals. An electric mine air heating system is used, with a propane system available as a backup.

Major underground mine infrastructure includes the primary jaw crusher, conveyors, ventilation raises, fans, heating system, pumping stations, electrical substations, explosives magazines, paste fill booster pump station, refuges, mine communications and other ancillary installations.

No changes to the underground mining methods are required to facilitate the proposed production increase.

3.5.1.2 Mine Design

3.5.1.2.1 Access and Ramp Infrastructure

Two independent internal ramps and surface portals, one for the VOK zone and one for the WZ, connect all levels of the mine to surface. The VOK decline and surface portal is located proximal to the mill and contains the conveyor that transports ore from the crusher to the mill, in addition to providing access/egress for the underground mine. The WZ portal is the second access/egress for the mine and is used to access the mechanical shops for underground equipment and to haul waste rock to surface. Figure 3.5-1 illustrates the general ramp development arrangement.

For ease of entry and exit, ramps are designed with a 25 m turning radius and a 15% gradient, levelling out to a 0% gradient in proximity to a level access intersection. Passing bays are incorporated where required. Figure 3.5-2 shows the ramp system for both zones in perspective view.

Figure 3.5-1. Underground Mine Access and Development Infrastructure.

Figure 3.5-2. Brucejack Declines and Ramp System.

3.5.1.2.2 Level Development

Sublevels are accessed from the ramps at a 30 m vertical interval as defined by the planned stoping heights. Footwall and hanging wall drives are typically set back a minimum of 22.5 m from the ore contact, whereas ramp development is set back a minimum 50 m from the ore contact. This arrangement promotes long-term geotechnical stability and provides space for the placement of ancillary services between the ramp and level development. Sublevels have ventilation raises on the east and west sides of the level access points.

Level development follows the general strike of the various lenses, providing access to the mineralized zones in a manner that promotes stope mining. Generally, level development is in the hanging wall, with hanging wall drives typically including excavations for sumps, refuges, transformers, remuck bays, paste fill line, and raise accesses.

Stope access crosscuts are on 15 m spacings, with the exception of those levels where sill extraction or near-surface weathered ore is recovered in smaller stopes as determined by the geotechnical requirements. The design shows extraction of fault zone ore in stopes that are retreated perpendicular to the axis of the fault. Figure 3.5-3 illustrates the typical mining approach and level development requirements in the 4950 tpd mine plan.

Lateral development design considered equipment size, services, and required activity. The design parameters are summarized in Table 3.5-1. Figure 3.5-4 and Figure 3.5-5 illustrate standard designs for hanging wall drives and the main decline, respectively.

Table 3.5-1. Development Design Parameters.

Development Type	Parameter		
	Width(m)	Height/Length(m)	Maximum Gradient (%)
Remuck	5.5	5.5	2
Footwall Drives	5.5	5.5	15

Figure 3.5-3. Typical Level Plan - 1200 Level in the VOK Zone.

Figure 3.5-4. Standard Designs - Hanging Wall Drive.

Figure 3.5-5. Standard Design - Main Decline.

3.5.1.2.3 Stope Design

The Brucejack Mine uses the Mineable Shape Optimizer (MSO) module from the Deswik mine planning software package to produce conceptual stope shapes. Table 3.5-2 summarizes the key design parameters used in the MSO. The conceptual stope shapes are refined as necessary to minimize planned dilution and to meet practical mining constraints. Individual areas meeting the cut-off grade are evaluated against access development costs to determine economic viability before including them in the mining plan.

For non-person entry excavations, such as long hole stopes, assessments of the stope dimensions presented in Table 3.5-3 are considered appropriate for the fair to good and poor to very poor rock mass classes (see Ground Control Management Plan, Appendix 9-2-4). Where stopes are planned within fault zones there is the potential for reduced stability and increased dilution. Further shortening of stope lengths is considered if adverse stope performance and dilution is unacceptable.

Table 3.5-2. Stope Design Parameters.

Parameter	Units	Valley of the Kings Zone			West Zone		
	Standard	Weathered[1]	Sill Pillar		Standard	Weathered[1]	Sill Pillar
NSR Cut-off	US$/t	185	185	185	180	180	180

Minimum Hanging Wall Dip	degrees	80	80	80	60	60	60

Note: [1]Refers to stoping in weathered material immediately below the surface crown pillar. Weathered material extends 10 to 50 m below surface.

Table 3.5-3. Maximum Stope Dimensions by Rock Mass Condition.

Rock Mass Condition	Maximum Stope Dimensions (m)
Fair to Good (RMR76 > 40)	15 w x 30 h x 15 to 40 l
Poor to Very Poor (RMR76 < 40)	15 w x 30 h x 15 l

3.5.1.3 Mining Method and Sequence

3.5.1.3.1 Block Definition

The orebody is divided into six blocks defined by elevation and zone, that facilitate production from multiple working areas. Mining progresses upward from the lowest elevation in each block. The general levels are defined in the long-term mine plan, but selection has been redefined for operational considerations. The current block sill levels for the VOK zone are located at the 960 masl, 1080 masl, 1200 masl, and 1320 masl elevation levels.

3.5.1.3.2 Stope Cycle

The primary mining method is transverse LHOS and is based on a standard primary/secondary sequence. No permanent pillars are required, and maximum ore extraction is targeted. The secondary mining method is lateral LHOS and stopes are mined this way when they are narrower in width and continuous in the direction perpendicular to the standard crosscut development.

When the footwall drives are completed, a through ventilation circuit is established before mining begins between any two levels. Crosscuts are driven from the footwall drive, through the centre of the stope, to the far ore contact on the undercut and overcut levels. Crosscuts on both levels are supported by long support-system cables and split sets from the central access to pre-support the roof prior to full-width slashing of the entire stope footprint. The secondary stopes are not slashed to full width for ground control considerations.

Long holes are drilled with parallel holes, or in fan configurations, depending on whether the stope can be safely slashed across the entire mineralized width. Once the stope footprint is planned, a 762 mm pilot hole is drilled in the slot raise location. Production drilling follows in the raise and slot area, followed by the production rings, as drilling progresses towards the end of the stope.

The raise and slot are generally opened in five shots or less. Production blasting and mucking proceed cyclically until the stope is depleted and all ore has been mucked out. Long hole open stoping is a non-entry method, with remote mucking of blasted ore required once the draw point brow is open to the extent where the operator may be exposed to uncontrolled sloughing from the stope cavity. The empty stope is remotely surveyed with cavity monitoring equipment. A barricade is constructed in the draw point and the stope backfilled to just below the floor elevation of the top level. Crushed aggregate or run-of-mine (ROM) waste is spread over the fill surface to reduce backfill dilution and increase trafficability of mucking equipment for the next lift of the stope.

In sills and other areas where top access is not available, mining proceeds in a similar manner; however, raise development and production drilling is performed via drilling up holes from the bottom level. Figure 3.5-6 illustrates the typical LHOS design for these areas.

Longitudinal LHOS is also employed at the mine. In contrast to transverse LHOS, mining progresses along the strike of the orebody to a common access point. Where applicable, the overcut and undercut are slashed to the footwall and hanging wall contacts, although in numerous longitudinal stopes no overcut is required, and ore is extracted via upwards drilling. In all other respects, the stope cycle is similar to transverse LHOS.

Figure 3.5-6. Typical LHOS Design.

3.5.1.3.3 Stope Sequence

The mining sequence in any area of a given block begins with extraction of the primary stopes on the first (lowest) level. Wherever feasible, the first primary stope is located near the middle of the lens to develop a pattern of stope extraction that moves outward to the extremities of the lens while progressing upward toward the top. This generally promotes a favorable redistribution of ground stress. When the adjacent primary stopes from the level above have been filled and cured, secondary stoping commences. Figure 3.5-7 illustrates typical sequencing for the more massive lenses at the mine.

Figure 3.5-7. Example of Primary / Secondary LHOS at Brucejack Mine.

3.5.1.4 Blasting Products

Several blasting products are used in the mining process, including emulsion, cartridge explosives, primers and boosters, detonators, and detonating cord, as described in Table 3.5-4.

Table 3.5-4. Blasting Products Used at Brucejack Mine.

Blasting Product	Description	Use at Brucejack Mine
Emulsion	Water resistant and produces lower levels of ammonium nitrate in mine water. Emulsion has reliable and consistent performance and can be left for a significant period of time in blastholes before firing.	Bulk emulsion is the primary explosive product used for both lateral development and stoping at the mine.
Cartridge Explosives	Prepackaged explosives that have either emulsion or nitroglycerine-based explosives in a paper, cardboard, or plastic wrapper.	Used in lateral development or alimak raise rounds. Sometimes used for main blast holes in a development round and/or in combination with smaller diameter trim products for perimeter holes.
Primers and Boosters	Basic solid cartridge explosive products. Size of the booster varies depending on hole size and blast type.	Used in conjunction with detonators to initiate blasting agents such as emulsion.
Detonators	Basic electric and non-electric (nonel) detonation systems.	Electric detonators are typically only used to initiate a blast using a central blasting system, while nonel are used for most blasthole initiation at the mine.
Electronic Detonators	Programmable detonator delays that allow for increased blast size, precision, and promotes better fragmentation by reducing delay scatter.	Generally used for longhole stoping.
Detonating Cord	Consist of a continuous high explosive core bound by textile yarns and finished with plastic and wax as waterproofing.	Various grain strengths of detonating cord are used at the Brucejack Mine, primarily to tie nonel detonators to an initiating electric cap. Detonating cord may also be used as a trim product in perimeter holes of development rounds.
Stemming	Non-explosive crushed rock (10 to 19 mm).	Used at times to confine the explosive energy at the collar of stope blast down holes, thereby improving blasting efficiency.

3.5.1.5 Backfilling

The primary means of backfilling is paste fill generated from unclassified tailings mixed with adequate cementitious binder to meet the strength requirements of re-exposure. Regular strength paste fill is commonly required where there will be re-exposure of vertical stope walls.

Stopes that will not be re-exposed by adjacent mining are backfilled with unconsolidated waste rock and/or by paste fill with sufficient binder to remove any risk of future liquefaction (low-strength paste fill). High-strength paste fill is used in the lower portion of all primary and secondary stopes that are undercut by sill extraction from below.

Disused headings in mined-out areas below the post-closure flooding elevation are used for development waste rock disposal. The disposal of waste rock in underground stopes reduces the total void volume requiring paste backfill, and therefore reduces the quantities of tailings that are backfilled underground.

3.5.1.5.1 Backfill Management Plan

A Backfill Management Plan (Appendix 3-3) has been developed and implemented for the Brucejack Mine in accordance with M-243 Condition C.2(f). The plan addresses paste and waste rock fill practices, including:

- Backfill preparation, pour, and monitoring safe work procedures;
- Paste bulkhead design;
- Tight fill procedures;
- Paste mix designs for various types of spills;
- Paste emergency procedures;
- Line flushing procedures;
- Paste pipeline pressure monitoring procedures; and
- Paste quality control procedures.

Standard operating procedures regarding the mine's backfill practices are provided as appendices to the Backfill Management Plan.

The general paste distribution principals required for long hole open stoping are not expected to change with the proposed increase in ore production rate; however, Pretium expects that higher through-put from the paste plant will be required to ensure timely filling of stope voids. The Backfill Management Plan and current paste pump and reticulation network will be reviewed by a qualified third party and updated as required to facilitate the proposed production increase.

3.5.1.5.2 Paste Backfill Distribution

The paste fill distribution system transports paste from the surface plant to the underground stopes via pipeline. The mine currently operates the system at a nominal flow rate of 100 m^3/h. Typically, the paste is pumped in the range of 63% to 67% solids, with cement ratios between 4.3% and 11% depending on stope strength requirements.

A positive displacement pump in the surface paste fill plant provides paste to the lower zones of the VOK zone below the 1380 Level. The paste plant pump also feeds a booster pump located at the 1345 elevation near the VOK zone. This booster pumps paste to the upper VOK zone (1380 Level and above). The underground booster pump station houses the positive displacement pump, the pump hopper, a water tank with a high-pressure pump for pipeline flushing and pump hydraulic packs.

The schedule of the pipe varies with the pressure rating of the area. Victaulic couplings are used as the connection method.

Instrumentation for controlled operation includes 10 permanent pressure gauges, three permanent cameras, automated diversion valves at the sumps, and integrated process control with the paste fill plant.

3.5.1.6 Ore Handling

3.5.1.6.1 Mucking

Once blasted from either stope development headings or long hole blasts, ore is trammed by conventional diesel or battery powered LHD from the muck pile to a haul truck or a remuck bay. The remuck bays allow for surge and grade blending capability near the crusher. The LHDs used in stope mucking are equipped with remote control capabilities to remove open stope hazards to the operator. Development and production LHDs are in the 14 to 18 t (8 to 10 yard) class. Haul trucks transporting ore to the crusher ROM bin or remuck bays are either 30 t diesel or 50 t battery powered.

3.5.1.6.2 Truck Dump and Crusher

At the scalping grizzly, material smaller than 600 mm falls through to the ore bin and larger material is broken down by a hydraulic rock breaker stationed above the grizzly screen. Figure 3.5-8 shows a sectional projection through the coarse ore bin with the rock breaker and scalping grizzly. The rock breaker has the capability to be operated from a sound attenuated operator's compartment or remotely from the crusher operating room via video link.

The ore bin feeds material down through a hopper at the bottom of the bin to an apron feeder. The jaw crusher reduces the larger material to 100 to 120 mm size and drops the product down the fines chute to the crusher belt conveyor. Figure 3.5-9 shows an isometric view of the crusher feed and crusher.

The crusher conveyor transports ore from the crushing area to the intermediate conveyor. During ore transport on the conveyor, tramp iron is collected by magnet and deposited into a steel waste bin. The first main conveyor transports the ore up the VOK decline to the transfer station and to the second main conveyor. The second main conveyor exits the decline into the portal structure, where the ore is dropped onto the mill feed conveyor. From the portal structure, the ore is carried to the mill through an elevated, heated and enclosed gallery to the top of the mill fine ore surge bin.

Figure 3.5-8. Truck Dump and Ore Bin Sectional Projection

Figure 3.5-9. Crusher Feed and Crusher Isometric View.

3.5.1.7 Operations Mobile Equipment

Table 3.5-5 summarizes the quantity and types of mobile equipment currently in use in the Brucejack underground mine. The optimal fleet capacity for the increased throughput is currently under evaluation. Pretium anticipates upgrading the haul truck fleet size from eight to a minimum of 11 for the proposed production increase and will operate predominantly 50 t BEVs. An additional electric LHD is also anticipated for the proposed production increase to 4950 tpd. Pretium is planning for all new haul trucks to be battery electrics vehicles.

Table 3.5-5. Underground Mobile Equipment.

Equipment	Total[1]	Description
Two Boom, Electric / Hydraulic Jumbo	4	Used to drill lateral face rounds for both ore and waste headings. Electric/hydraulic bolters are used to install primary ground support in the ribs and back of development headings.
Single Boom Jumbo	1	
10 YD diesel powered LDH	1	Used to muck, tram, dump, and load both ore and waste into haul trucks.
8 YD diesel powered LHD	9	
3.5 YD diesel powered LHD	1	
30 tonne diesel powered haul truck	9	Used to transport both ore and waste. Planned to replace diesel powered equipment.
50 tonne battery electric truck	3	
Top Hammer Long Hole Drill	3	Production drilling is primarily completed with top hammer drills and ITH hammer drills. Some of the ITH drills can be fitted with V30 heads to drill the slot drop raises. The ITH drills are also used for level-to-level raises and utility holes.
ITH Long Hole Drill	2	
ITH Longhole Drill RC	5	
Explosives loader, diesel, emulsion (development face charger)	2	Load both development and production blast holes with emulsion and detonators. The loaders are equipped with appropriately constructed and separated compartments for carrying the emulsion, detonators, detonating cord, and boosters. The loaders are equipped with auto-retracting loading hoses.
Explosives loader, diesel, emulsion (production blasting)	1	
Shotcrete sprayer	1	Used to apply wet-type shotcrete on an as needed basis.
Transmixer	2	Equipped with a cement mixing drum transport shotcrete from the batch plant to the sprayer.
Emulsion Hauler and carriers	3	Used to transport bulk emulsion from surface to storage tanks in the underground magazines. The truck transports up to its 17,000 kg capacity of emulsion in custom ISO tanks to the underground storage tanks. The emulsion is pumped from the ISO tanks to the 21,000-L storage tanks. The carriers are used to transport emulsion from the emulsion storage to the development faces and stopes for loading.
Scissor Lift	6	Used to allow miners to work safely at height while installing utilities such as pipe and power cables. Scissor lifts are equipped with levelling jacks to provide a stable platform.
Personnel transport	48	Include diesel powered Kubota rough terrain vehicles, tractors equipped with additional seating, and dedicated crew carriers.
Misc. Support Utility and Telehandlers	16	Mechanics' lube trucks equipped with lubricant/fuel storage, and onboard air compressors for servicing equipment. A motor grader equipped with a low-profile cab and 12-foot long mold board is used to maintain underground roads.
Boom Truck	7	Flat deck trucks with onboard boom cranes are used to transport mining supplies from surface to underground storage/working areas. The boom trucks are equipped with outrigger jacks for stability.
Electric/hydraulic Maclean Bolter	6	Used to install cable bolts in the stope backs and in development intersections, as required. Bolters are used to drill the holes, then cables are installed manually, and grout is pumped into the hole containing the cable. Cable bolts are 6 to 12 m lengths.
Tamrock Bolter	1	

1. *Numbers in use as of 2022 to support 3800 tpd production rate. Additional BEV mobile equipment is expected to support the production increase.*

3.5.1.8 Ventilation

The ventilation system is designed to meet requirements in the Health, Safety and Reclamation Code for Mines in British Columbia (the Code) (EMLI 2022). The total ventilation requirements for mine operations are based on the airflow required for the diesel-powered mobile equipment fleet, underground fixed facilities and a leakage and balancing factor. The current total airflow requirement for the Brucejack Mine is as follows:

- Diesel equipment: 345 m^3/s
- Fixed facilities: 55 m^3/s
- Leakage and balancing (10%): 40 m^3/s
- Total – 440 m^3/s

All diesel-powered equipment operating underground is fitted with Canada Center for Mineral and Energy Technology certified engines or cleaner tier 4 engines. Additional air is supplied for fixed facilities and a leakage and balancing factor.

The ventilation design is based on a “push” configuration, with permanent surface fans and air heaters located at the WZ and VOK portals. These two intake airways provide sufficient ventilation capacity to support steady state mining operations. The VOK production ramp is connected to the intake ramps to deliver fresh air to the active production levels. An escape-way ladder system is installed in fresh air raises in parallel with the production ramp.

Fresh air travels from the production ramp, along the footwall drives and is exhausted to return air raises located at the extremities of the level. There are four exhaust raises to surface, with VR5 scheduled for development in 2025. Regulators are installed at the raise connections to distribute the required volume of air to the level. An appropriately designed auxiliary fan and duct system forces fresh air to development headings and active stope faces.

The underground fixed facilities have a dedicated return air raise to eliminate the introduction of dust and other unwanted contaminants into the production areas. The volume of air flowing through the crusher area is controlled with a combination of fans and regulators. Figure 3.5-10 shows an isometric view of the Brucejack ventilation system. Additional details regarding the mine’s ventilation systems are provided in the Production Ventilation Plan (Appendix 9-2-10).

The additional mobile equipment required to accommodate the proposed production rate increase are planned to be BEVs (Section 3.5.1.7). Therefore, no further changes beyond the installation of VR5 are required for the proposed 4950 tpd mine plan.

Figure 3.5-10. Brucejack Mine Underground Ventilation System – Looking West

3.5.1.8.1 Primary Fans

For operational flexibility over LOM, the primary fans include a variable frequency drive and adjustable pitch blades. The fans and motors can deliver the required duty to meet the demands of the production and development activities over the current LOM. Summary specifications of the primary fans are provided in Table 3.5-6.

Table 3.5-6. Primary Fans – Summary Specifications

Description	Specification
Fan Diameter	2.4 m
Type	Horizontal mount axial mine fan. Adjustable pitch blades.
Configuration	Two forcing fans, each connected with ducting to the WZ decline and conveyor decline (VOK portal)
Voltage	600V
Fan Motor	600 kW to 900 revolutions per minute, variable frequency drive capability

3.5.1.8.2 Mine Air Heating

The heating system is designed and installed as per the Code requirements (EMLI 2022). All intake air entering the mine is heated above the freezing point for the following reasons:

- to protect the health and safety of personnel working or travelling in intake airways;
- to prevent the freezing of service water and discharge lines;
- to ensure reliable operation of conveying and other mechanical equipment in the decline;
- to maintain ice-free and safely trafficable roadways;

- to prevent rock surface (or shotcrete lining) expansion/contraction damage from freezing and thawing of rock joints in the upper parts of the intake airways; and
- to prevent ice build-up in airways that would potentially lead to unsafe conditions.

Mine air heaters are positioned in front of permanent primary fans. Four MWs (two MWs per fan) of electrical heaters are installed as the primary heating method. Propane heating is installed to augment the electrical heating in extreme cold conditions.

3.5.1.8.3 Auxiliary Ventilation

All work areas, such as development headings and drawpoints not supplied with a direct flow of fresh air using auxiliary systems. The auxiliary systems consist of axial fans and flexible ducting. The fan power and duct size are specified to provide the required amount of air for each activity. Figure 3.5-11 shows a ventilation configuration for a typical production level with auxiliary fans ventilating active areas.

Figure 3.5-11. Ventilation Configuration for Typical Production Level.

3.5.1.9 Geotechnical Assessment and Ground Control

3.5.1.9.1 Geotechnical Design Basis

Initial site investigations and geotechnical assessments that continue to inform mine planning and design were completed by BGC Engineering Inc. and Pretium personnel. These initial assessments included:

- Geological and geotechnical drilling and logging;
- Borehole televiewer surveys;
- Rock core and discontinuity laboratory testing;
- Groundwater pressure monitoring;
- Rock mass and mechanics characterization;
- Structural geology interpretation;
- Geotechnical mapping; and
- Excavation and pillar stability analyses.

A comprehensive presentation of the assessment data is presented in BGC (2013) and summarized in the Ground Control Management Plan (GCMP) (Appendix 9-2-4). The geotechnical performance of excavations in the existing mine are reviewed regularly, with updates to the GCMP completed annually by Pretium. No changes to the geotechnical design basis are anticipated to accommodate the proposed production increase.

3.5.1.9.2 Ground Control Management Plan

The Brucejack GCMP is the authoritative record of data, information, and systems used to manage ground control at the mine. The key objectives of the plan are to reduce and / or mitigate the risks of uncontrolled ground failure and contribute to the development and maintenance of a safe and productive mining environment.

These objectives are achieved through:

- Clear definitions of ground control roles and responsibilities for key individuals;
- Ongoing assessment of the mine's geotechnical conditions, and evaluation of ground control risks;
- Design and implementation of ground control management systems;
- Development of standard operating procedures that address ground control issues;
- Communication of ground control matters and hazards within the workforce;
- Ground monitoring systems, and ground support testing;
- Internal and external auditing; and
- GCMP review, and scheduled updating.

The Brucejack GCMP is provided in Appendix 9-2-4. No changes to the Ground Control Management Plan are anticipated to accommodate the proposed production increase.

3.5.1.10 Subsidence Potential

A preliminary assessment of subsidence potential was completed by BGC Engineering Inc. (BGC 2013). Site-specific conditions and factors affecting the potential for subsidence indicate a very low probability that noticeable subsidence will occur. The two potential subsidence mechanisms identified at the Brucejack Mine are crown pillar failure and plug failure, both of which are mitigated by tight placement of cemented pastefill in the mined-out stopes and the installation of cable bolts in the upper stopes to reinforce the crown pillar. The preliminary assessment (BGC 2013) is appended to the Subsidence Monitoring and Management Plan prepared by SRK Consulting Inc. in 2020 as per MA-243 Condition D.13 (Appendix 9-2-8).

3.5.2 Processing Plant (Mill Building) and Associated Facilities

3.5.2.1 Overview

The process plant produces a gold and silver bearing flotation concentrate, and gold and silver doré from melting the gravity concentrate produced from the gravity concentration circuits. The final flotation concentrate is dewatered and removed offsite by ground transport. The gravity concentrate is smelted in the gold room on site to produce gold-silver doré. The process plant is designed to operate two 12-hour shifts per day, 365 days per year. The gold room is scheduled to be operated during day shifts only.

A portion of the flotation tailings is used to produce paste for backfilling excavated stopes in the underground mine, with the remaining balance deposited subaqueously in the WRTSF. Tailings are thickened prior to deposition in the WRTSF or use in paste backfilling, and the water from the tailings thickener overflow is recycled within the mill building as process make-up water. Treated water from the WTP is used for mill cooling, gland seal service, reagent preparation, and make-up water.

3.5.2.2 Process Flowsheet

The process flowsheet developed for the Brucejack mineralization is a combination of conventional bulk sulphide flotation and gravity concentration to recover gold and silver, and consists of the following:

- Primary crushing underground;
- Conveying system for crushed ore;
- A surge bin with a live capacity of 3,300 t on surface;
- Grinding and gravity concentration;
- Rougher/scavenger flotation;
- Cleaner/scavenger flotation;
- Gravity concentrate smelting to produce doré;
- Flotation concentrate dewatering, and load out; and
- Tailings thickener and disposal to the WRTSF or to the underground mine for paste backfilling.

A simplified flowsheet for the operation at 4950 tpd is shown in Figure 3.5-12.

Figure 3.5-12. Simplified Process Flowsheet at 4950 tpd.

To facilitate the production increase from 3800 tpd to 4950 tpd, the following upgrades to the mill are anticipated:

- Grinding circuit: increasing cyclone feed capacity and associated piping; increasing belt conveyor capacity
- Gravity separation/concentration: upgrading gravity feed pump capacity, splitter box, , and an additional safety screen and Knelson concentrator
- Flotation: pre-flotation trash screen installation, rougher concentrate to cleaner flotation bypass, flotation circuit pump upgrades, and a new rougher cell
- Tailings circuit: thickener bypass to tailings disposal tank, and thickener underflow pump upgrade

These upgrades will be completed within the existing mill structure and will not require additional surface disturbance.

3.5.2.3 Process Plant Description

3.5.2.3.1 Primary Crusher (Underground)

The primary crushing facility is located underground. The major equipment and facilities for the underground primary crushing facility include a hydraulic rock breaker, a stationary grizzly, a jaw crusher (150 kW), an apron feeder, associated dump pocket and belt conveyor, belt scales, and a dust suppression system.

The particle size of the jaw crusher feed is typically less than 500 mm. The jaw crusher reduces the ROM material to 80% passing 100 to 120 mm. A rock breaker is installed to break any oversize rocks at the stationary grizzly prior to the jaw crusher.

The crushed product is transported by a conveyor system from the underground primary crushing facility to the semi-autogenous grinding (SAG) mill feed surge bin located on surface. The primary crushing and conveying facilities are equipped with dust suppression systems to control fugitive dust generated during crushing and conveyor loading. The crushing and conveying system are monitored by closed-circuit television and can be controlled from the process central control room located in the process plant.

3.5.2.3.2 Mill Feed Surge Bin

Crushed product from the underground primary crushing facility is conveyed to the transfer tower and then further transported to the SAG mill feed surge bin. The transfer tower, located within the portal building, receives crushed material from the underground primary crushing facility and transfers the ore onto the surge bin feed conveyor system.

Ore from the mill feed surge bin is reclaimed by two apron feeders onto the SAG mill feed conveyor. The stocking and material handling system for the crushed ore includes jaw crusher discharge belt conveyors, a transfer tower located in the portal building, a belt conveyor to feed the SAG mill feed surge bin, a mill feed surge bin, two apron feeders, and local dust collection systems. Each of the

crushed ore transfer points is equipped with a dust collection or suppression system to control fugitive dust that is generated while transporting the crushed material.

3.5.2.3.3 Primary Grinding, Classification, and Primary Gravity Concentration

A SAG mill/ball mill circuit is used for primary grinding. The circuit is equipped with two centrifugal gravity concentrators that recover gold/silver grains that are liberated or partially liberated from their host minerals. The grinding circuit consists of a SAG mill and a ball mill in a closed circuit with classifying hydrocyclones and a centrifugal gravity concentrator. Grinding is conducted as a wet process.

The grinding/gravity concentration circuit currently includes:

- One SAG mill driven by a variable frequency drive (VFD);
- One ball mill powered by a VFD;
- Two hydrocyclone feed slurry pumps;
- Six hydrocyclones;
- Two centrifugal gravity concentrators and ancillary screens;
- Pebble crusher, powered by a fixed drive;
- One particle size analyzer; and
- Five online samplers.

Crushed ore from the surge bin is reclaimed onto a set of belt conveyors that feeds ore to the SAG mill. The SAG mill is equipped with pebble ports to discharge oversize pebbles from the SAG mill, and the SAG mill discharge is screened by an external vibrating deck. Oversize material from the vibrating screen is transported by belt conveyors to a pebble crusher (or bypass) that discharges back onto the SAG mill feed belt, while undersize is discharged by gravity to the hydrocyclone feed pump box in the grinding circuit.

The ball mill operates in a closed circuit with hydrocyclones and two centrifugal gravity concentrators. The product from the ball mill is discharged into the gravity concentrator feed pump box. The entire ball mill discharge reports to the gravity concentration circuit. The stream is split in two and each stream feeds a safety screen with the undersize reporting to the centrifugal gravity concentrator. The gravity concentrator tailings reports to the hydrocyclone feed pump box, where it is pumped to the hydrocyclones. The gravity concentrator tailings are combined with the SAG mill vibrating screen undersize slurry. The blended slurry in the pump box is pumped to the hydrocyclones for classification. The hydrocyclone underflow returns by gravity to the ball mill. Steel balls are manually added into the mills on a batch basis as grinding media.

The gravity concentration process recovers gold particles from the ball mill discharge. Tailings from gravity concentration return to the hydrocyclone feed pump box for pumping. The gravity concentrate transfers by gravity to the gold room for further upgrading by tabling. Tailings from the tabling are further processed by a centrifugal concentrator in the gold room. The concentrate produced from the centrifugal concentrator is recycled back to the tabling circuit while the tailings transfer by gravity to the gravity concentrator feed pump box. The concentrate from the tabling circuit is further upgraded by smelting

using an electric induction furnace at site. The gravity concentration circuit has a security enclosure and CCTV cameras, and access is restricted to authorized personnel only.

Dilution water is added to the grinding circuit as required. A particle size analyzer monitors the particle size of the hydrocyclone overflow, in conjunction with an automatic sampling system and required instrumentation such as solid density, pressure, and flow rate meters.

To facilitate the increased production rate, a third centrifugal gravity concentrator and ancillary safety screen will be installed. Discharge from the ball mill be split between three stream feeds to the gravity concentration circuit.

3.5.2.3.4 Rougher and Scavenger Flotation

The pulp from the primary grinding circuit is subjected to conventional flotation to recover the free gold, silver, and their bearing minerals from the materials being processed. Flotation reagents are added to the flotation cells as defined through testing. The flotation reagents include potassium amyl xanthate as the collector and a proprietary frother blend. Concentrates produced from the rougher flotation circuit are pumped to the cleaner flotation circuit. The rougher flotation tailings are further processed by rougher scavenger flotation, along with the tailings from the cleaner scavenger flotation cells. The rougher scavenger concentrate is pumped with the rougher concentrate to the cleaner flotation circuit. Rougher and scavenger flotation is carried out at the natural pH level (without slurry pH adjustment). The rougher/scavenger flotation circuit consists of four 100 m^3 rougher flotation tank cells and two 100 m^3 scavenger flotation tank cells.

Tailings from the flotation circuit are transfered to the tailings thickener. Depending on the mining operation requirement, the thickener underflow is pumped to the paste backfill plant for excavated stope backfilling underground and/or to the WRTSF for subaqueous deposition. Automatic sampling systems collect samples required for process optimization and metallurgical accounting.

An additional rougher flotation cell will be added to accommodate the production increase.

3.5.2.3.5 Cleaner Flotation

The rougher and rougher scavenger flotation concentrates undergo three stages of cleaning by flotation to produce a final gold-silver bearing concentrate.

The major equipment in the cleaner flotation circuit includes:

- Four 15 m3 tank cells for the first cleaner flotation;
- Two 15 m3 tank cells for the first cleaner/scavenger flotation;
- Two 15 m3 tank cells running in parallel for the second cleaner flotation; and
- One 30 m3 tank cells for the third cleaner flotation.

The rougher and rougher scavenger concentrate is initially upgraded in the first cleaner tank cells. The resulting concentrate is pumped to the second cleaner circuit, while the tailings report to the cleaner scavenger flotation cells for further flotation. The cleaner scavenger flotation concentrate is recycled to the head of the first cleaner flotation cell bank together with the tailings from the second cleaner

flotation. The first cleaner scavenger flotation tailings are pumped to the rougher scavenger flotation feed box.

The concentrate from the second cleaner flotation stage is further upgraded by the third cleaner flotation, and the second cleaner tailings are pumped to the first cleaner flotation. The concentrate from the third cleaner flotation cells, which is the final concentrate, is pumped to the concentrate thickener. The third cleaner tailings are recycled back to the head of the second cleaner flotation circuit.

Reagents used in the primary bulk flotation circuits are added to first stage of cleaner flotation to float the target minerals. The cleaner flotation process is carried out at the natural slurry pH level.

3.5.2.3.6 Flotation Concentrate Handling

The concentrate from the third cleaner flotation is thickened, filtered, and loaded into bins prior to being transported to an off-site smelter(s). The concentrate handling facility has the following equipment:

- One high-rate thickener;
- Two peristaltic (hose) slurry pumps;
- One concentrate filter feed stock tank;
- One Larox pressure filter; and
- One bulk concentrate handling system.

The final flotation concentrate is pumped to the concentrate thickener. Flocculant is added to the thickener feed well to aid the settling process. The thickened concentrate is pumped to the concentrate stock tank. The concentrate stock tank is an agitated tank, which serves as the feed tank for the concentrate filter. A tower-type pressure filter is used for further concentrate dewatering. The filter press reduces the approximate moisture content of the thickener underflow to between 6 and 9%. The filter press solids are discharged through a surge bin and into a concentrate container. The concentrate containers are transported by ground to Stewart, BC for export.

The filtrate from the pressure filter is circulated back to the concentrate thickener feed as well as dilution water. The overflow from the concentrate thickener is pumped to the first rougher flotation cell.

3.5.2.3.7 Gravity Concentrate Upgrading and Smelting

The gravity concentrates produced from the primary grinding circuit are upgraded by conventional tabling followed by smelting to produce gold-silver doré.

Key equipment installed in the gold room includes:

- Two gravity concentration tables—one for the primary centrifugal gravity concentrate, and one for the secondary centrifugal gravity concentrate;
- Three concentrate storage bins;
- One secondary centrifugal gravity concentrator with concentration bowl;

- One table concentrate drying oven;
- Flux reagent storage;
- Flux mixer;
- Induction melting furnace;
- Off-gas and dust scrubbing system; and
- Ancillary equipment, including doré cleanup station.

The centrifugal gravity concentrate from the primary grinding circuit transfers by gravity to a holding bin. The holding bin collects gravity concentrate over a 24-hour period. After 24 hours, the stored concentrate is transferred by gravity to the primary shaking table. The concentrate from the table is dewatered, dried in a drying oven, weighed and stored in the vault prior to smelting. The tabling middling products are recycled back to their respective table feed stock bins. The table tailings are pumped to a secondary centrifugal gravity concentrator located in the gold room. The concentrate from the secondary centrifugal gravity concentrator reports to the secondary tabling storage bin. The secondary concentrator operates only while the shaking table is operating. The secondary storage bin is then transferred to the shaking table every three to five days. Tailings from the primary gravity concentrators is transferred by gravity to the hydrocyclone feed pump box. Tailings from the secondary gravity concentrator is transferred by gravity to the gravity concentrator feed pump box.

The dried tabling concentrate is mixed with flux, which consists of borax ($Na_2B_4O_2$), sodium nitrate ($NaNO_3$), silica sand (SiO_2), soda ash ($NaHCO_3$), and manganese dioxide (MnO_2). The concentrate and flux mixture is charged into an induction furnace and melted at approximately 1,300°C. The metal melt and slag is poured into bar molds in a cascade-casting arrangement. The doré bar is sampled while molten, cooled (with water), dried, cleaned (using hand power tools), weighed, stamped, and stored in the vault prior to being shipped to refiners.

The slag from the melting is crushed by a small jaw crusher and sampled. The remaining slag is stored at site for up to three months and transported off site to a precious metals recovery center.

A wet scrubbing system is used to ventilate and clean the off-gas generated during the flux mixing and melting operation. Sufficient ventilation is provided in the gold room to protect the operators. All clothes, gloves, and other safety equipment necessary for high-temperature protection is provided to the operators working in the secure area.

3.5.2.3.8 Flotation Tailings and Water Treatment Plant Sludge Management

The flotation tailings from the flotation circuit are dewatered using a high-compression-type thickener prior to being pumped either to the paste backfill plant for underground backfilling or to the WRTSF for subaqueous deposition. Sludge from the WTP is pumped to the tailings disposal stock tank where it is mixed with the thickened tailings prior to being pumped to the WRTSF for sub-aqueous deposition. Figure 3.5-13 shows the tailings and the sludge management flowsheet.

Flotation tailings from the flotation circuit are produced at a solids density of approximately 28% w/w. The flotation tailings are pumped to the tailings thickener feed well where an anionic flocculant is added to assist dewatering performance. Solid flocculant is prepared in a standard manner in a wetting and mixing system into a dilute solution prior to being dosed into the thickener feed well at a controlled rate. The thickening process currently dewaters the tailings to a solids density

at approximately 60 to 70% w/w. The overflow from the thickener is recycled to the mill process circuits as process water.

Depending on the backfill operating schedule, the thickened tailings are pumped either to the backfill plant to produce paste for underground mine backfilling or to the WRTSF for subaqueous deposition.

The intake water from the underground mine and the water from the CWP are pumped to the WTP. After treatment, the treated water is used as mill fresh water or discharged to the WRTSF. Approximately 65% of the process water used is recycled from the WTP. The WTP sludge is pumped to the tailings disposal surge tank, where it is mixed with thickened tailings prior to being pumped to the WRTSF for sub-aqueous disposal.

When the backfill plant is in operation, the tailings thickener underflow is pumped to a thickened tailings stock tank. The thickened tailings from the stock tank are blended with cement and water in a paste mixer to generate paste backfill. The paste is pumped to the excavated underground stopes for backfilling.

Figure 3.5-13. Flotation Tailings and Water Treatment Plant Sludge Management Flowsheet.

3.5.2.4 Tailings Disposal

The final tailings from the flotation circuit are thickened prior to being pumped either to the backfill plant for underground disposal or to the WRTSF for subaqueous deposition. The tailings handling equipment and facility components include a cone thickener with associated pumps, a mixing tank for tailings discharged to the WRTSF, a backfill plant to produce tailings paste for underground backfilling (including a tailings storage tank), and two paste slurry pumps and associated pipelines.

Control measures within the operation of the tailings system include on-line instrumentation coupled with technicians to oversee the operation and maintenance of the instrumentation and automation systems. Visual observation of operating conditions and manual checks to ensure instruments are functioning properly is closely aligned.

3.5.2.5 Assay and Metallurgical Laboratories

The assay laboratory, located within the mill building, is equipped with the necessary analytical instruments to provide all routine assays for the mine and process plant. The critical assay laboratory equipment and instruments include:

- Sample preparation equipment (e.g., jaw crushers, pulverizers, screens, splitters, weigh scales and drying ovens);
- Fire assay-related furnaces and devices;
- Wet chemistry lab for digestion of samples and rocks and associated equipment (e.g. hot plates, digestion blocks, fume hoods and balances;
- Analytical instruments (e.g., atomic absorption spectroscopy for Au and Ag, inductively coupled plasma OES for multi-element analysis and microbalances); and
- Two Leco sulphur and carbon analyzers.

The metallurgical laboratory monitors metallurgical performance, and its results are used to improve process flowsheet unit operations and efficiencies. The laboratory is equipped with a laboratory-sized rod mill, particle size analysis sieves, bench scale flotation cells, centrifugal gravity concentrators, filtering devices, sample splitting devices, balances, and pH meters.

3.5.2.6 Water Treatment Plant

The WTP is able to maintain effective treatment at influent flow rates between 1,400 m^3/d and 10,000 m^3/d. The nominal total suspended solids (TSS) concentration is 1,300 mg/L and the nominal treatment flow rate is 6,000 m^3/d. The WTP is designed to chemically precipitate targeted dissolved metals and remove influent TSS and the resultant chemical precipitates. A simplified WTP schematic is presented in Figure 3.5-14.

No significant changes to the water treatment plant design or process are required to facilitate the proposed production increase. A third disc filter may be installed to increase redundancy in the polishing filtration process. Additional details regarding water treatment are provided in Chapter 5, Section 5.6.1. A Best Achievable Technology report has been prepared and is provided in Appendix 5-4.

Figure 3.5-14. Simplified Water Treatment Plant Schematic.

3.5.2.6.1 Process Description

The WTP receives influent from the underground workings and the CWP via the 1350 Level mine sump pump and the CWP pumps, respectively. The mine sump pump includes four parallel pump trains consisting of two high pressure pumps in series operating on VFD, flowmeters, pressure, pH

and turbidity instrumentation. The CWP pumps include four submersible pumps with flowmeters on VFD, two 30 hp pumps, and two 75 hp pumps.

The WTP includes redundancy features and systems to maintain a robust process, including, but not limited to:

- Dual stage metal precipitation and Actiflo® units with downstream discfilter capacity. This full sequence of unit processes is not necessary to achieve water quality requirements during normal operations but adds additional water treatment capability in case one unit process is not operating optimally for mechanical, process or other reason.
- Two discfilters operated in parallel. A third discfilter is planned for future installation.
- Lab turbidity and pH meters are available to operators to verify the accuracy of automated instrumentation.
- Redundant duty/spare chemical dosing systems are installed in the WTP reagent area.
- The sulfuric acid dosing system is installed with duty/standby pumps.
- Duty/standby pumps are installed in all process applications to ensure continuous availability.

If for any reason the plant is unable to handle water requiring treatment, the influent is redirected to the CWP. Water already in the WTP is also directed to the CWP. CWP water levels are managed throughout the year to allow for storm surge or process upset containment.

3.5.2.6.1.1 Influent Water Clarifier

The influent water clarifier consists of a high rate settling clarifier with recirculation pumps. Influent water streams (underground water, CWP and process water) are introduced to the top of the clarifier, anionic flocculant is added and solid particles agglomerate and settle to the bottom of the clarifier. Underflow pumps withdraw the settled sludge, which either recirculates back to the top of clarifier to enhance thickening, or discharges to the tailings thickener in the mill.

The underground clarifier consists of a high rate settling clarifier; sludge recirculation /disposal pumps; and instrumentation, including overflow flowmeter, pH and turbidity probes.

3.5.2.6.1.2 Metal Precipitation

Combined influent water overflows the clarifier and enters the metal precipitation reactor. Ferric sulphate and hydrated lime are added to initiate coagulation and precipitation of heavy metals. Sludge removed from the downstream primary Actiflo® unit is recycled back to this reactor to assist with heavy metals precipitation and reduce chemical requirements. The pH of the metal reactor is maintained between 8.5 and 9.5 utilizing hydrated lime.

The metal precipitation reactor consists of a rectangular tank, high speed agitators, instrumentation including dual pH meters and discharge slurry pumps consisting of a pumpbox vessel and discharge pumps.

3.5.2.6.1.3 Primary Solids Removal (Primary Actiflo®)

Slurry from the metal precipitation reactor is pumped to the primary Actiflo® unit for removal of suspended solids. Functionally, Actiflo® is a sand-ballasted settling unit that employs a high-rate

coagulation/flocculation/sedimentation process. It utilizes microsand which provides a surface area that enhances flocculation and acts as a ballast or weight. Physically, Actflo® is a multi-chambered tank consisting of three agitated reaction chambers and a settling chamber.

Anionic flocculant is added to each of the first three agitated chambers. The coagulated solids combine with fine grained silica sand to form a high density, rapidly settling floc that separates in the final settling chamber equipped with lamella plate separators. Settled sand and sludge is removed from the bottom of the settling chamber, while solids free water overflows the settling chamber for further downstream processing. The sand and sludge mixture is pumped to a hydrocyclone, which separates the sand from the sludge. The sand returns to the agitated chambers of the Actiflo unit, while the sludge is transferred to a solid collection standpipe. The standpipe will allow some of the sludge to recirculate to the front of the WTP (metal precipitation reactor). The excess sludge reports to further dewatering and ultimately disposal with thickened tailings.

The primary Actiflo® unit includes one Actiflo® unit, high speed agitators, low speed scraper/rake system, sand recirculation pumps coupled with hydrocyclones and process instrumentation including turbidity and pH meters.

3.5.2.6.1.4 Polishing Solids Removal (Polishing Actiflo®)

Solids free water from the primary Actiflo® then flows into an agitated polishing reactor, where additional ferric sulphate and hydrated lime are added. The pH is maintained at approximately 7.5 to target different heavy metals that have lower solubilities at a circumneutral pH. Slurry from the polishing reactor is sent to the polishing Actiflo® unit for removal of suspended solids. The polishing Actiflo® behaves in an identical manner as the primary Actiflo®. Sludge from the polishing Actiflo® reports to sludge handling, while clarified overflow reports to polishing filtration.

The polishing reactor includes a tank, high speed agitators and process instrumentation including a pH meter.

3.5.2.6.1.5 Polishing Filtration

Polishing filtration removes fine suspended solids not previously captured by the Actiflo® units. Ten micron filters continuously remove residual solids from the water. The solids are discharged back to the front of the WTP and the filtered water continues downstream for final pH adjustment.

The discfilters are comprised of two 10 µm discfilters in parallel. Addition of a third 10 um discfilter is planned to provide added redundancy.

3.5.2.6.1.6 pH Adjustment

Treated water from polishing filtration, which has completed all solids and dissolved metals removal steps, is subjected to a final pH adjustment prior to controlled discharge. Sulphuric acid or hydrated lime is used to bring the pH of the water to a range between 6.5 to 8.5. Due to the operation of the polishing Actiflo® at a target pH of 7.5, very little pH adjustment is needed at the final stage.

The final pH correction tank includes a tank, high speed agitator and instrumentation including a pH sensor and a tank level indicator.

3.5.2.6.1.7 Treated Water Distribution

Treated water is monitored continuously for turbidity and pH levels, and sampled twice per month for metals and general parameters required by PE-107835, to ensure it meets the WTP discharge limits specified in PE-107835 Section 1.2. If the treated water meets the WTP discharge limits, it is allowed to discharge from the treated water tank to the WRTSF. If the treated water does not meet the discharge limits, discharge to the WRTSF is halted and the treated water tank discharges via controlled overflow to the CWP. A portion of the water discharged from the treated water tank is directed to the mill freshwater tank for use in the mill or underground mine. In all, the water distribution system includes four pumps in total.

The treated water tank includes a tank with process instrumentation that includes a turbidity and pH meter, and flow meters on each of the discharge pipes to the WRTSF and the CWP and an automated motorized valve for the discharge line leading to the WRTSF.

3.5.2.6.1.8 Sludge Handling

Metal precipitate sludges report to sludge handling where the fine precipitates are separated and recycled back to the metal precipitation reactor. Excess sludge not needed for the WTP process is sent for disposal with thickened tailings to the WRTSF in accordance with M-243 Condition D.3(c)(viii).

The sludge dewatering system includes the primary Actiflo® sludge tank, polishing Actiflo® sludge tank, and process instrumentation for each of the primary and polishing Actiflo® sludge tanks, including TSS analyzers and a flowmeter for the sludge wasting line.

3.5.2.6.1.9 Chemical Makeup and Dosing

The WTP includes reagent makeup and distribution systems for all chemicals required in the system. Hydrated lime slurry is prepared from bulk bags of hydrated lime. Ferric sulphate solution is prepared from bulk bags of ferric sulphate salt with a small quantity of sulfuric acid added to aid salt dissolution. Concentrated sulfuric acid is distributed directly from totes. The anionic polymeric flocculant solution is prepared from dry flocculant.

The reagent system includes:

- Lime preparation and dosing system including:
  - Dry lime hopper with screw feeder;
  - Lime mixing tank complete with agitator; and
  - Lime holding tank complete with agitator.
- Lime recirculation pumps and actuated proportional control valves for injection of lime into system.
- Ferric sulphate ($Fe_2(SO_4)_3$), preparation including:
  - Dry ferric sulphate hopper with screw feeder;
  - Mix tank with agitator;
  - Holding tank; and
  - Ferric sulphate dosing pumps;
- Sulphuric acid dosing system including;

  - Storage tote and transfer tote; and
  - Four electronic diaphragm dosing pumps;
- Anionic polymer preparation package including:
  - Polymer hopper with screw feeder and vacuum eductor;
  - Polymer mix tank with agitator; and
- Polymer holding tank;
- Six positive displacement dosing pumps.

3.5.2.6.1.10 Reagent Handling and Storage

Potassium amyl xanthate and frother is added to the flotation process slurry stream to modify the chemical and physical characteristics of mineral particle surfaces, and to enhance the floatability of the valuable mineral particles into the concentrate products. Flocculant is used as a settling aid for the flotation concentrate and tailings thickening. Anti-scalant is added as required to protect pipelines and process equipment. Liquid sodium hydroxide is used to prepare an alkaline solution for smelting furnace exhaust scrubbing.

Potassium amyl xanthate is shipped to the mine in solid form. The reagent is diluted to approximately 10% solution strength in a mixing tank and stored in a holding tank in the mill building. The solution is added to the various addition points by metering pumps. Freshwater is used to make up the required solution strength.

Frother is shipped to the plant as liquid in bulk intermodal containers. The reagent is stored in a holding tank in the mill building and pumped in undiluted form to the points of addition using metering pumps.

Solid flocculant is prepared in a wetting and mixing system to a diluted solution of less than 0.2% solution strength. The solution is stored in a holding tank in the mill building prior to being pumped by metering pumps to the thickener feed wells.

Anti-scalant chemicals are delivered in liquid form and added to the gravity concentrators and gland water system as required to minimize scale build-up in the water pipelines and process equipment. This reagent is added in undiluted form.

To ensure containment in the event of an accidental spill, each reagent preparation and storage facility is located within its own dedicated containment area in the mill building, designed to accommodate 110% of the content of the largest tank. The storage tanks are equipped with level indicators and instrumentation to prevent spills. Appropriate ventilation, fire and safety protection, and Safety Data Sheet stations are provided in these areas.

Each reagent line and addition point is labelled in accordance with Workplace Hazardous Materials Information Systems (WHMIS) standards. All operational personnel have WHMIS training, along with additional training for the safe handling and use of the reagents. Additional details regarding reagent handling and storage are found in the mine's Chemicals and Materials Storage and Handling Plan (Appendix 9-1-6).

3.5.3 Tailings Storage Facility and Associated Infrastructure

3.5.3.1 Facility Overview

Operation of the Brucejack Mine generates waste rock from mine development and tailings from ore processing. Waste rock is classified as PAG and is either directed to the WRTSF for subaqueous deposition or retained in underground mine secondary stopes as backfill. Thickened tailings are used to generate cemented paste backfill to fill/support voids in the underground workings and the remainder is deposited subaqueously to the WRTSF as tailings.

The maximum WRTSF water depth at the beginning of mine operations was approximately 85 m with an initial storage capacity of 28.5 Mm^3. The previously approved 3800 tpd mine plan (Pretium 2018b) allows for deposition of approximately 11.9 Mt of tailings and approximately 7.8 Mt of waste rock within the WRTSF during the LOM. The 4,950 tpd mine plan does not increase the overall tailings and similar waste rock deposition tonnages to the WRTSF. Actual deposition tonnages into the WRTSF at the end of 2021 are recorded to be 3.56 Mt of tailings and 5.74 Mt of waste rock. From 2022 until the EOM, the 4,950 tpd mine plan has 7.8 Mt of tailings and 2.0 Mt of waste reporting to the WRTSF, for a total LOM tonnage of 11.3 Mt and 7.9 Mt, respectively. The 19.2 Mt (or 12.2 Mm^3) combined total of waste rock and tailings planned for deposition in the WRTSF is less than the overall total storage available of 28.5 Mm^3.

All waste rock and tailings produced by the mine is contained within WRTSF without the need for any external containment structures. Within the footprint area of the WRTSF, lakebed sediments are dominated by sand, silt and clay particles and range in thickness between 5 m and 35 m, based on ground penetrating radar conducted in 2014. Geotechnical investigations conducted in 2022 generally confirmed the lakebed sediment thicknesses at the sample locations selected for cone penetration test-work. Tailings have a gradation where typically 80% of the particle sizes, by mass, are smaller than 162.4 µm. The milling strategy targets a maximum particle diameter of 0.3 mm.

Specific waste rock deposition procedures have been prepared to manage instability risks on the foundation of fine-grained sediments. These are discussed and documented in the Waste Rock and Tailings Storage Facility – OMS Manual (Appendix 9-1-17).

3.5.3.2 Waste Rock Deposition

Waste rock is transported from the underground mine to the WZ pad where it is transferred into surface haul trucks that deliver waste rock to the WRTSF. The waste rock is either temporarily stockpiled on the surface of the WRD (within the WP1 stockpile) or dumped 45 m from the crest, or at a safe setback distance designated by the Brucejack geotechnical site team, then pushed off the crest of the WRD by remote dozer.

The WRD is divided into nine zones, from Zone 1 (west side of WRTSF, adjacent to outlet) to Zone 9 with a design dump crest surface elevation of 1365 masl or approximately 0.5 m above the average water level in the WRTSF (Appendix 9-1-17). A temporary surface stockpile (WP1) is intended to be used for times when deposition into the WRTSF may not be possible, such as during periods of heavy ice cover in the WRTSF.

The waste rock deposition method has undergone several changes since the start of deposition in 2015. The current method used to deposit waste rock into the WRTSF is by remote operated dozer

push (as of May 2021 to date) which evolved from previous conventional dozer, telestacker and excavator bailing methods. The change to remote operated dozer was part of the response to the relatively lower deposition rates which could be achieved with the telestacker and excavator bailing methods. The previous waste rock deposition methods are still considered viable waste rock management options, and may be deployed as required, to maximize operational flexibility.

Waste rock deposition rates are determined primarily by the length of the active crest frontage. The design basis assumes daily deposition is approximately 7 m^3/d per meter of crest frontage. As described in Appendix 3-1-1, the design basis deposition rate conservatively accounts for equipment downtime. Assuming that waste rock deposition is suspended during winter months (December 15 to May 1), the average annual deposition rate is approximately 1,596 m^3/yr per m of crest frontage. This annual total (>1 Mt/yr at 2.06 t/m^3) exceeds the maximum waste rock to WRTSF tonnages (849 kt) presented in Table 3.3-2. Throughout the LOM, overall waste rock production will decrease, as will the required crest frontage to facilitate waste rock deposition. This principle would also apply with the EWRD should Pretium proceed with pursuing the contingency.

Pretium's geotechnical engineers prepare daily deposition plans that assign deposition activities in the WRD to the nine sequential zones. Deposition procedures are detailed in the WRTSF OMS Manual (Appendix 9-1-17). The primary considerations for waste rock deposition include the following:

- The deposition of waste rock leads to rapid undrained loading of the foundation sediments at the bottom of the WRTSF. Because characteristics of foundation sediment vary across the deposition area, the magnitude of settlement and preloading time are not consistent but require continuous monitoring and interpretation by the senior site geotechnical engineers with support from the WRTSF Engineer of Record as necessary.
- As deposition occurs, it is expected that minor surficial failures of the waste rock slope and outer foundation will occur. The deposition plan has been designed to allow for these to occur safely. The monitoring plan has been designed to monitor for the development of any larger failures that could affect the safety of those working on or around the WRTSF.
- Pretium's senior site geotechnical engineers oversee the preparation of the dump management plans to ensure appropriate foundation preloading times have elapsed, based on settlement rates and observational data before additional waste rock is deposited. Deposition planning is completed on a daily basis.
- Quantifiable performance objectives (QPOs) for settlement rates are followed to ensure stability of the WRD. QPOs and WRTSF deposition management practices are provided in detail in the WRTSF OMS Manual included in Appendix 9-1-17.

To facilitate depletion of WP1 and to control the rate of waste rock deposition due to pore pressure generation at the current WRD platform and mine operations, Pretium has adopted a GNSS (Global Navigation Satellite System that provides real time hourly settlement data. This eliminates downtime due to poor visibility and reliance on optical surveys. It also allows for identification of accelerated settlement much earlier and rapid response to mitigate overloading. This allows Pretium to adhere to the QPO for sustained periods of time and increase the crest line available for deposition with time. Additionally, Pretium commissioned a second remote dozer which provides redundancy and reduces delays associated with maintenance of the existing dozer.

As a contingency method for waste rock management, an additional waste rock dump site at the east end of the WRTSF (East WRD) is under evaluation. The East WRD would provide additional

deposition capacity via new deposition zones (increased crest frontage), thereby increasing the mine's flexibility to deposit waste rock into the WRTSF. The 4,950 tpd waste rock and tailings deposition plan (Appendix 3-1) takes this into consideration and incorporates the East WRD development. As the East WRD is intended improve the mine's waste rock deposition capabilities regardless of production rate, its authorization, if pursued by Pretium, would be sought via an M-243 amendment application separate from the 4950 tpd production uplift application.

3.5.3.3 Waste Rock Dump Management

Brucejack Mine operations personnel manage PAG waste rock exposure following M-243 Condition D.3(c)(iv) that requires that all PAG waste rock reporting to WRTSF be subaqueously deposited within two years of exposure, and Condition D.3(c)(v) that limits temporary waste rock storage on surface to two years.

The design basis for the active Brucejack Mine waste rock stockpile is the Updated Subaqueous Waste Rock Dump Design report (SRK 2018; Appendix 3-4) submitted to and approved by EMLI during the 2018 3800 tpd production increase application (Pretium 2018b). The approved design uses the observational method (Terzahghi and Peck 1967, Peck 1969), as the WRTSF is not a typical subaerial surface waste dump. The WRD design includes the temporary stockpile WP1, as it is located on and is integral to the WRD.

As the temporary surface waste rock stockpile WP1 has accumulated and grown over time, additional management considerations and design have been developed for continued safe operations of the WRD. A geotechnical assessment that includes a summary of the subsurface conditions, design criteria, slope stability analyses, seismic hazard classification, and instrument monitoring recommendations for WP1 is presented in Appendix 3-2.

Following the waste rock dump platform partial crest failure on 16 July 2022, a significant delay in depleting the temporary surface stockpile WP1 in 2022 occurred. This was taken into account and incorporated in the deposition plan for 4950 tpd as shown in Appendix 3-1. Further, the deposition plan in Appendix 3-1 incorporates a potential EWRD and additional WP2 stockpile(s) to demonstrate how this contingency infrastructure could be applied. The EWRD and WP2 stockpile(s) are not required to manage waste rock at the 4950 tpd production rate.

Temporarily stored PAG waste rock nearing the end of the allowable exposure period is managed through a combination of the following three methods:

- Sub-excavate PAG waste rock that is approaching an exposure time of two years, to a minimum depth of 1 m below water surface and replaced with NPAG waste rock.
- Sub-excavate PAG waste rock that is approaching an exposure time of two years, to a minimum depth of 1 m below water surface and replaced with PAG waste rock which has been immediately removed from mine development areas.
- Sub-excavate PAG waste rock that is approaching an exposure time of two years to a minimum depth of 1 m below water surface and retain a temporary pond in the excavated area.

Details of the waste rock dump management are provided in the WRTSF OMS manual Appendix 9-1-17.

3.5.3.4 Tailings Deposition

Tailings are produced during the process of milling the ore and are either placed back into the underground mine as a paste backfill, or deposited subaqueously in the WRTSF, dependent on operational needs. Tailings that report to WRTSF are conveyed through tailings pipelines that discharge subaqueously within 7.5 m of the WRTSF bottom in accordance with PE-107835 Section 1.3.

Deposition procedures are detailed in the Waste Rock and Tailings Storage Facility – OMS Manual (Appendix 9-1-17). The primary considerations for tailings deposition include the following:

- Sludge generated from the WTP is mixed in the tailings thickening tank with mine tailings and discharged to the WRTSF. WTP sludge is added to tailings in a mixing ratio that is less than 2% sludge by dry weight in accordance with PE-107835 Condition 1.4 and M-243 Condition D.3(c)(viii).
- The tailings conveyance system consists of two main heat-traced high-density polyethylene (HDPE) pipelines that enters a valve house structure where the slurry can either be distributed to the operational lines.
- The submerged elevations of the discharge pipes are adjusted or replaced as needed to maintain compliance with the 7.5 m distance above WRTSF bottom PE-107835 requirement.
- Digital bathymetric survey scans are completed annually to determine the elevation of the deposited tailings surface and depths of the pipeline outfalls. The beach slope varies at both the previous suspended cable supported pipelines and the perimeter discharge. The lakebed perimeter discharge pipeline beach slope varies from 10.5% to 3% and is effectively flat with distance.
- Ongoing monitoring of operations and TSS levels in the WRTSF during operation provides input for adjusting and optimizing the slurry densities throughout the LOM.
- It is anticipated that the subaqueous tailings deposition footprint will overlap with the subaqueous waste rock deposition footprint, resulting in waste rock being partially deposited onto a foundation of tailings beginning in 2022 on the easternmost side of the WRD.

Four additional tailings lines are planned for phased installation to replace the existing tailings pipelines as deposition progresses (Table 3.5-7; Appendix 3-1). The planned pipelines will be located according to the existing requirements in Section 1.3.2 of PE-107835.

Table 3.5-7. Planned Tailings Pipeline Discharge Locations and Recommended Installation Timing.

Tailings Line ID	Coordinates (Northing)	Coordinates (Easting)	Discharge Elevation (m)	Earliest Recommended Construction Year	Active Discharge Years
Line #5	427712.87	6258838.04	1318.21	Constructed	2022-2023
Line #6	427791.05	6258801.20	1322.26	Constructed	2022-2023
Line A	427730.45	6258818.47	1329.49	2023	2023-2025
Line B	427833.56	6258786.00	1334.95	2023	2025-2027
Line C	427723.47	6258807.98	1341.95	2024	2026-2029
Line D	427834.13	6258767.00	1345.60	2026	Standby

Emergency shut down procedures for the tailings discharge pipelines are provided in the Waste Rock and Tailings Storage Facility – OMS Manual (Appendix 9-1-17).

3.5.4 Water Management Structures

3.5.4.1 Overview

The mine's water management system consists of a network of diversion channels, collection ditches, weirs, sumps, and HDPE piping designed to divert non-contact water away from the mine site area and collect contact water for treatment and use in the mill process. Contact water in the CWP is pumped to the WTP, located in the mill building. The effluent from the WTP is either used as process water or discharged to the WRTSF.

Details of the mine's water management system and operations, including design drawings of the water collection systems, CWP, and LLW, are provided in Pretium's OMS Manual – Water Management Plan (Appendix 9-1-18). In accordance with *MA* Permit M-243 Condition C.4(e), the OMS Manual – Water Management Plan is reviewed annually at minimum. Updates to the manual are completed during the annual review, as required.

With the exception of the addition of a fourth Filterboxx C75 wastewater treatment unit (Section 3.5.4.6), no design or effluent monitoring changes to mine's water management systems are required to facilitate the proposed production increase.

3.5.4.2 Non-Contact Water Diversion Channels

Non-contact water from up-gradient of the mine site is intercepted by two diversion channels: Camp Creek (West) diversion and Johnson Creek (East) diversion. The Camp Creek diversion directs Camp Creek into Brucejack Creek. The Johnson Creek diversion drains the creek into the WRTSF.

3.5.4.3 Contact Water Management System

Contact water within the core infrastructure area of the mine site, where the main excavations of surface bedrock occurred during construction to create building pads, is directed to the CWP via weirs, ditches, sumps, and HDPE piping. A catchment area of approximately 15 ha currently reports to the CWP.

The CWP has been designed with sufficient storage capacity (approximately 50,000 m^3) to contain a 24-hour, 200-year return period rain-on-snow event (Q_{200}). Water within the CWP is pumped to the WTP at a maximum rate of 200 m^3/h, which is sufficient to prevent the pond from overtopping for the 200-year return period for rainfall events up to 10 days in duration. The CWP is managed such that sufficient storage is maintained for Q_{200}. An emergency spillway with an inlet at 1376.5 masl allows for controlled releases from the CWP to the WRTSF.

Influent from the CWP to the WTP is continuously monitored in-line at the mill for turbidity, pH, and flow rate, as per *EMA* Effluent Permit PE-107835. Water quality samples of the CWP influent are collected bi-weekly. In the event of a direct discharge event to the WRTSF, additional monitoring and water quality sampling is implemented, as described in Appendix A of PE-107835. Additional details on monitoring programs are provided in Chapter 7.

3.5.4.4 Underground Mine

Water pumped from the underground mine workings is directed to the WTP, where it is treated prior to use in the process plant or discharged to the WRTSF when there is an excess of process water available.

As per *EMA* Effluent Permit PE-107835, underground dewatering rates, including turbidity and pH, are monitored continuously as mine water influent at the WTP. Influent water quality samples are collected bi-weekly. Additional details on monitoring programs are provided in Chapter 7.

3.5.4.5 WRTSF Outlet Weir (LLW)

The LLW is located within Brucejack Creek at the outlet of the WRTSF. The facility houses effluent flow monitoring instrumentation and water reclaim equipment that supplies fresh water to the mill. The compound cross-section consists of a concrete, broad-crested structure with a low-level opening to pass average annual flows and an overflow crest to pass peak flows (up to Q_{200}). The LLW is enclosed in a concrete chamber founded on bedrock with a grating floor and heated superstructure above it. This configuration keeps the weir ice free during the winter period.

Conceptual drawings of the weir design are provided in Figure 3.5-15 and Figure 3.5-16. Water enters the upstream chamber through an underflow baffle, passes over the weir, and exits the downstream chamber through another underflow baffle. The reclaim water pumps are mounted on the floor above the upstream chamber. The water passes through a dividing wall into a secondary chamber through two openings, which are offset to either side of the pump intakes to minimize turbulence upstream of the weir. The weir and flow monitoring instrumentation are located in a secondary chamber.

Flow mixing is promoted by the inlet and outlet underflow baffles and by turbulence caused by water flowing over the weir crest. This design feature helps ensure that the effluent is well mixed prior to water quality sampling at the downstream end of the weir chamber. Automated instrumentation is in operation to continuously measure water level, which is converted to a flow rate using an equation for a rectangular broad-crested weir. Effluent discharge quality samples are collected weekly, and continuous flow monitoring is supplemented with quarterly manual flow measurements as per EMA Effluent Permit PE-107835. Additional details on monitoring programs are provided in Chapter 7.

Figure 3.5-15*. Conceptual LLW facing upstream (looking east)*

Figure 3.5-16*. Conceptual LLW cross section (looking north)*

3.5.4.6 Domestic Wastewater Treatment

Domestic wastewater at the mine site is treated using three Filterboxx C75 self-contained units with a total permitted effluent discharge rate of 175 m^3/day, 365 days/year (Condition 1.5.1 of PE-107835). Effluent from the STP is directed to the WTP discharge tank where the two effluents are combined and discharged through a single line to the WRTSF. Domestic wastewater sludge is dewatered to reduce the moisture content (minimum of 25% to 30% solid content, as per Condition 1.7.6 of *EMA* Air Permit PA-107025) and then discarded into the general waste stream or incinerated on site.

The addition of a fourth Filterboxx C75 unit is proposed as part of this production increase amendment. While there is capacity for an approximately 25% increase to the camp population within the existing permitting discharge limits, this amendment application is conservatively requesting the additional C75 unit to maintain redundancy of 1 full treatment unit in the event that capacity beyond 150 m^3/d treatment is utilized.

3.5.4.7 Freshwater Supply System

Water is supplied to a fresh/fire water storage tank in the mill from the LLW reclaim and WTP treated water. Aside from emergency and fire water, the freshwater from this tank is primarily used in the mill for slurry pump gland water, reagent and process water make-up, mine supply water, gravity concentrator fluidization water, and the gold room scrubber.

3.5.4.8 Potable Water Supply

Potable water is supplied from a groundwater well authorized under the BC *Water Sustainability Act* Conditional Water Licence #116102. Groundwater is pumped from the well to the potable water treatment plant where it undergoes filtration and disinfection prior to distribution. The potable water treatment and distribution system is authorized by a Permit to Operate issued under BC Northern Health.

3.5.5 Ore, Overburden, Soil and Construction Stockpiles

Approximately 30,000 m^3 of overburden is stockpiled at the mine site for reclamation purposes, in one stockpile. The overburden stockpile material is discussed further in Chapter 4. As there is no new surface construction/development for the proposed production rate increase, there will be no additional stockpiling or soil or construction materials.

3.5.6 Mine Access and Mine Haulage Roads

As per the mine's ML/ARD Management Plan (Appendix 9-1-11), only material classified as NPAG is excavated for use in road construction and/or road maintenance. Geohazard risks and mitigation measures related to access and haul roads within the mine site area are described in the mine's Geohazards Management Plan (Appendix 9-2-3) and Avalanche Safety Plan (Appendix 9-1-5).

If Pretium pursues authorization for the East WRD, a haul road will be required to transport waste rock to the WP2 stockpile(s) and dump site. As described in Section 3.1, the haul road design for East WRD and WP2 access road will be provided through a separate application for authorization.

No additional mine access or mine haulage roads are required to facilitate the production rate increase.

3.5.7 Power Supply and Distribution

3.5.7.1 Transmission Line

The Brucejack Mine's power is supplied by BC Hydro via a 138 kV transmission line (1L403) originating at LNT substation in Stewart and terminating at the independent power producer LNL station. The mine taps into 1L403 approximately 10 km from LNT and 1 km from LNL. The tap line runs approximately 1.5 km to the Brucejack terminal station (BJT). From the BJT, the 138 kV overhead line runs approximately 44 km to the Knipple substation where the voltage is stepped down to 69 kV. A 69 kV transmission line runs 13 km from the Knipple substation to the Brucejack substation. The northernmost 19.5 km of the transmission line, including the Knipple substation, is within the M-243 authorization area.

The 69 kV overhead line to the mine site terminates at a manual disconnect switch on the terminal gantry located outside of the mill pad at the 6020 tower. On the load side of the switches the 69 kV circuit transitions to single conductor insulated cables that are routed below-grade through a cable trench to the Brucejack substation located within the mill building.

The existing electricity supply agreement with BC Hydro for Brucejack demand is for 19.4 MW at 0.97pf (20 MVA). An application has been submitted to BC Hydro to increase the supply delivered through the 138 kV line to 35.5 MVA. The 138 kV line is adequately rated for an increase up to 35.5 MVA, and the 69 kV overhead line from the Knipple Substation to Brucejack mine is of sufficient capacity to increase to 35.5 MVA. Therefore, no changes or upgrades to the existing transmission line infrastructure are required for the proposed production rate increase.

3.5.7.2 Knipple Substation

The Knipple substation has two transformers rated 20/26.6 MVA that operate in an n+1 configuration allowing continued operation up to 26.6 MVA on one transformer. The Knipple substation is regularly operated on a single transformer in the winter for snow clearing.

For redundancy, installation of a third transformer installed in parallel at the Knipple substation is being evaluated, though not required. The existing transformers are adequate to accommodate the proposed production rate increase.

3.5.7.3 Brucejack Substation

The Brucejack substation is located inside the mill building and is comprised of two transformers rated 15/20/25 MVA, 69 kV-4.16 kV. The substation is a two-level design with a transformer vault on the ground floor and a switchgear room (69 kV and 4160 V) on the floor above to facilitate bottom entry equipment.

For redundancy, installation of a third transformer installed in parallel at the Brucejack substation is being evaluated, though not required. The existing transformers are adequate to accommodate the proposed production rate increase.

3.5.7.4 Backup Power Generation

The backup power system is comprised of 15 diesel reciprocating generators (four 0.5 MW, two 1.45 MW and nine 1.825 MW) connected to the 4160 V system at the DPS. In total, the back-up generators can produce approximately 21.3 MW of power when running at 100% load and running n+0. In a backup power scenario, the main power system is routed through the DPS electrical room to the central mill, portal building, and main camp electrical rooms, as well as the underground VOK substation.

No changes to the backup power system are anticipated to facilitate the proposed production rate increase.

3.5.7.5 Mine Site Surface Power Distribution

The 69 kV circuits feeds two circuit breakers which feed two parallel 69 kV to 4.16 kV transformers. The secondary of the transformers is connected via cable bus to the plant's main 4160 V switchgear which serves as the main switching point for the plant distribution system. Radial feeds from the 4160 V switch gear distribute power to the central mill, portal building, and main camp electrical rooms, as well as the DPS and underground VOK substations. The system is designed as secondary selective scheme with a tie-breaker such that the entire plant load can be carried by a single transformer in the event of failure or scheduled maintenance.

No changes to surface power distribution are anticipated to facilitate the proposed production rate increase.

3.5.7.5.1 Underground Electrical Demand and Distribution

3.5.7.5.1.1 Power Requirements

Ventilation, mining equipment, dewatering, paste backfill and underground crushing/conveying are the main consumers of power for the underground mine. The current peak underground load is approximately 8.0 MVA, and a typical mining level can have up to 1345 kVA of connected load. As development advances deeper into the mine, the dewatering power demand will increase due to a higher lifting head and increased inflows. A second underground paste backfill pump is under evaluation and may be added in 2023 depending on stope sequencing.

As described in Section 3.5.7.1, an application has been submitted to BC Hydro to increase the supply delivered through the 138 kV line to 35.5 MVA. Both the 138 kV and 69 kV transmission lines are adequately rated for 35 MW.

3.5.7.5.1.2 Underground Electrical Distribution

The underground mine distribution system is at 4160 V. Power is supplied by 4160 V circuits through the WZ portal, the VOK portal and a surface to underground borehole, to ensure the availability of an alternate and physically independent power source in cases of emergency. In the event of a loss of normal utility power to the Brucejack substation on the surface, the plant standby diesel power system can energize any underground 4160 V circuit to power critical loads (Section 3.5.7.4). The VOK underground substation has permanent distribution equipment at both 4160 V and 600 V to feed crushing, ore conveying, dust collection, paste backfill, and mine dewatering activities. Portable mining equipment in the form of mine load centers are located at each mining level and other key load locations. MLC ratings range from 500 kVA to 1500 kVA.

A transition to 13.8 kV was initiated as part of the 5-year plan in 2020. To that end, dual primary (5/15 kV) mining substations and 15 kV trunk cable have been installed and are energized temporarily at 5 kV. The cables run from the underground distribution center at the 1290 Level to the 1080 Level. As described in the 2020 Mine Plan Update (Pretium 2020b), all MLCs from the 1080 Level and below will be changed over to 13.8 kV primaries or replaced entirely. After the 15 kV system has been implemented, the upper areas of the mine (1140 Level and up) will remain powered by the 4160 V system.

No changes to underground electrical distribution are anticipated to facilitate the proposed production rate increase.

3.5.8 Explosives Storage Facilities

3.5.8.1 Surface Magazines

Explosives are stored on surface in two magazines located at km 73.3, approximately 20 m north of the road, with a combined total storage capacity of 5000 kg and up to 2000 detonators. The surface magazines supply explosives required for the mine's avalanche control program.

No additional surface magazines are required to facilitate the proposed production rate increase.

3.5.8.2 Underground Emulsion Storage

Bulk emulsion is stored in two underground storage tanks (21,000 L and 17,000 L) in two emulsion storage bays, each with roll-up fire door access (Figure 3.5-17). Bulk emulsion is delivered from the WZ to the underground storage bays via a custom-built underground emulsion hauler. Bulk emulsion is then transferred into the storage tanks with a pneumatic emulsion pump.

It is expected that a third underground emulsion bay will be required to facilitate the additional emulsion storage that is anticipate proposed production rate increase. The emulsion bay will be positioned to optimize distance and clearance based on the mine sequence, and the design will be consistent with the existing emulsion storage bays described in Figure 3.5-17.

Figure 3.5-17*. Bulk Emulsion Storage - Plan and Sections.*

3.5.8.3 Underground Magazine

All other explosive products (excluding bulk emulsion and detonators) are stored on wooden shelving in an underground powder bay (Figure 3.5-18). A fourth bay is designated for the storage of detonators on wooden shelves.

No additional underground magazines are required to facilitate the production increase.

Figure 3.5-18*. Cap and Powder Storage - Plan and Section.*

3.5.9 Ancillary Facilities and Support Infrastructure

No additional changes to the mine's ancillary facilities and support infrastructure, beyond that which is described in the preceding sections, is anticipated to facilitate the proposed production rate increase.

4. RECLAMATION AND CLOSURE PLAN

4.1 Introduction

This chapter summarizes key content of the Brucejack Mine Reclamation and Closure Plan, provided as Appendix 4-1. The Reclamation and Closure Plan addresses mine infrastructure components and site disturbance authorized under M-243, including mine development within the PMA portion of the mining leases (Figure 1.4-4) and the portion of the mine's transmission line extending south from the mining leases to Pretium's Mineral Claim #1026976 (Figure 1.4-5). Permit M-243 authorizes the northernmost 19.5 km of the transmission line, whereas the 37.5 km segment located south of that is authorized under Statutory ROW #6408729 (Figure 1.4-1).

Based on the 4950 tpd mine plan (refer to Chapter 3), the remaining mine life is approximately 7 years, with operations ceasing at the end of 2029. This will be followed by a closure phase estimated at three years that includes two years of closure and reclamation within the M-243 area, and a third year of reclaiming off-site mine related infrastructure (i.e., the BJAR and adjacent infrastructure below Knipple Glacier and extending to the Highway 37 intersection, and the Statutory ROW authorized portion of the transmission line). A post-closure monitoring period of ten years is planned for the M-243 area following mine closure.

Brucejack Mine surface disturbance areas are limited in extent due primarily to it being an underground mine. The M-243 approved PMA is 659.3 ha (Figure 1.4-4 and Figure 1.4-5), with approximately 195 ha covering a 100 m corridor along the northernmost 19.5 km of the transmission line, and the remaining approximately 464 ha being located within the mining leases. Actual disturbance at end of 2022 was calculated at 278 ha (terrestrial disturbance area total for mine site 55 ha, buffer from historical exploration 66 ha, transmission line 66 ha, WRTSF and Waste Rock Platform 76 ha, and km 72 NPAG quarry 14 ha), however the historical exploration buffer areas are minimally disturbed and have been partially reclaimed. The terrestrial disturbance area total for the mine site primary infrastructure area is 55 ha (lower and upper camps 5 ha, plant site 38 ha, pond 0.02 ha, roads 11 ha, overburden stockpile 0.4 ha, CWP 0.7 ha), which includes mine site infrastructure and related disturbance areas. The transmission line calculated surface disturbance is primarily within the 6.7 km southernmost segment that is below the tree line. Most of the northernmost 12.8 km of the transmission line is comprised of clear spans over bedrock and ice; towers in this section are anchored in bedrock.

There is no new surface disturbance associated with the proposed production rate increase, and therefore the Reclamation and Closure Plan does not include changes specific to the 4950 tpd Joint Application with the exception of infrastructure timing shown on the reclamation progression figures (e.g. WRTSF related mine wastes extents and mine closure in 2029). The Reclamation and Closure Plan has however, been updated to reflect surface infrastructure changes since the 2020 update (Pretium, 2020b) and for planned or proposed changes that are required for the existing mine operation irrespective of increasing the production rate from the present average 3800 tpd.

Key content changes in the updated Reclamation and Closure Plan compared to the 2020 Update (Pretium, 2020b) are as follows:

- Updated areas of disturbance, including based on 2022 orthophotography. This includes all disturbance within the mining leases extents, including within the PMA (both mining and

surface exploration related) and surface exploration outside of the PMA but within the mining leases.

- Maps and figures updated to include camp infrastructure changes completed in 2021, new truck shop planned for completion in 2023, and updated PMA (Amendment #8, approved November 2022).
- Five Year Mine Reclamation Plan updated to reflect mine closure in 2029, and mine progression figures changed to reflect waste rock and tailings extents based on the 4950 tpd mine plan. Areas of disturbance within the WRTSF remain the same (no change to the PMA).
- Addition of a proposed east WRD in a location similar to that included as an option in the Tailings and Waste Rock Subaqueous Deposition Management Plan included as Appendix 6-O of the 2015 MA/EMA Permits Application (Pretium, 2015), along with preliminary information on three proposed associated temporary surface PAG rock stockpiles and access road connection through and from the km 72 NPAG Quarry area. This infrastructure is required for and proposed outside of the 4950 tpd Joint Application. Arrangements of this proposed infrastructure depicted in the Reclamation and Closure Plan are at a design concept level.
- Updated information on the reclamation research program in progress.
- Content provided in response to updated joint application information requirements (MEMPR & ENV 2019), including with respect to ecohydrological modeling for the mine site; landforms and drainage pre-mine, during operations, and post-mine; and temporary closure content.
- Changes to some aspects of closure approaches, including increased commitment to remove some types of waste materials (e.g. HDPE and PVC) and dispose of these off-site at licensed facilities.

4.2 End Land Use and Capability Objectives

End land use and capability objectives for Brucejack Mine components have been integrated with mine planning and design to promote successful reclamation and closure. The mine and its operations have been planned and designed to minimize the terrestrial development footprint and to prevent significant adverse effects on the downstream aquatic receiving environment, including both water quality and aquatic biota.

M-243 Condition E-3 requires Pretium to “reclaim the land with the intent of re-establishing average pre-mining capability to the following end land use objective: wildlife habitat, particularly matrix habitat for mountain goat, grizzly bear and hoary marmot on the mine site and high elevation sections of the transmission line, and moose and grizzly bear habitat at lower elevations of the transmission line. Achieving land capability objectives and habitat enhancement shall guide the reclamation program.” Part E of M-243 contains additional reclamation related requirements.

4.2.1 Mine Site

The Brucejack Mine site primary surface infrastructure area is located along the southwest shore of the WRTSF in an area dominated by gossanous (mineralized materials to surface) bedrock outcropping with some slightly weathered parent materials occurring as pockets with alpine vegetation (Figure 4.2-1). Matrix habitat at the mine site is a rocky area with limited vegetation cover that does

not provide life requisites for wildlife species (e.g., forage, cover, or other key habitat values), but which provides connectivity for animals to access adjacent habitat. It differs from a movement corridor in that it does not provide foraging value. As such, a central objective of reclamation planning for the mine site is to prevent the creation of obstructions or hazards to post-closure movement of wildlife.

Pre-mine, the Brucejack Mine site was characterized as dominantly exposed bedrock, with approximately 80% of the mine site described as non-vegetated or sparsely vegetated (Figure 4.2-2), and with limited extent and poor quality of soils (ERM Rescan 2014a). The mine site is located above the tree line in the CMAun BEC zone. This zone has the harshest climate of any biogeoclimatic zone in BC. Temperatures are low for most of the year, with much wind and snow. Temperatures remain low even during the growing season, which has an exceptionally short frost-free period. Mean annual temperatures range from 0°C to 4°C. Patches of snow, névé, and firn persist late into the year.

Figure 4.2-1. Brucejack Advanced Exploration 2013, Showing Mine Site Bedrock Outcrops and Pockets of Weathered Parent Materials.

Figure 4.2-2. Brucejack Mine Site 2012, Showing Bedrock Exposures and Limited Vegetation Extent.

Vegetation community development within the mine site and its vicinity was limited by the poor quality and limited availability of growth media, high snow pack, high winds and low temperatures.

Pre-mine habitat assessments of the mine site classified the habitat as matrix habitat for wildlife species resident in the general vicinity: hoary marmot, grizzly bear, and, to a more limited extent, mountain goat (ERM Rescan 2013i). Aerial and ground surveys in 2012 and 2022 found hoary marmot colonies northwest and west of the mine site, along and near Brucejack Creek. Beginning during Pretium's advanced exploration activities in 2011, grizzly and/or black bears have been occasionally observed passing through the area north of Brucejack Creek and the (now) WRTSF, or south and high above the mine site along the winter access that traverses the upper VOK area.

An additional consideration pertinent to end land use is that growth media (unconsolidated overburden and soils) at the mine site have naturally elevated metals concentrations, including arsenic, due to being located on gossanous material.

At closure, the mine site will be reclaimed to matrix habitat for mountain goat, grizzly bear and hoary marmot to facilitate movement by these target species and others, into better habitats. This will be achieved by reclamation measures that result in terrain that is free of mine related obstacles or hazards, thereby allowing free movement through the area by wildlife. The post-closure mine site will have low vegetation cover, consistent with its pre-mine condition and with surrounding areas, as most of the adjacent landscape is comprised of unvegetated bedrock exposures.

4.2.2 Transmission Line

Most of the M-243 portion of the transmission line route is located either above the tree line or in high subalpine areas. Transmission line construction was helicopter supported, with road-based support within the M-243 section limited to a few towers near the BJAR. Transmission line tower base sizes vary with the tower type, with most being approximately 3 m in diameter. Towers were sited on bedrock as much as possible (Figure 4.2-3). Due to all of these factors, surface disturbance and effects on vegetation as a result of the transmission line are relatively limited.

At closure, the transmission line will be reclaimed to wildlife habitat, particularly matrix habitat for mountain goat, grizzly bear and hoary marmot in the high elevation sections, and moose and grizzly bear habitat at lower elevations of the transmission line. Transmission line development has not altered terrain except to a very limited extent (approximately 200 m length) at Knipple transfer area.

Transmission line infrastructure will be removed during final reclamation. Removal of the towers, conductors and Knipple substation will remove whatever limited obstacles to wildlife movement are posed by the transmission line. Due to the lack of soil disturbance between tower sites in the southern vegetated portion of the M-243 transmission line extent, the limited extent of tower sites on materials other than bedrock, and because where present, disturbed soils around tower bases have already been seeded and additional reclamation will be conducted as feasible once towers are removed, the end land use objectives for the transmission line are expected to be achieved.

Figure 4.2-3. Transmission Tower on Bedrock in M-243 Vegetated Section (Photo August 2019).

4.3 Reclamation Approaches

4.3.1 Background

The Brucejack Mine site area has multiple unique or unusual characteristics that present substantial challenges for vegetation establishment and are not typical of mines in BC. These characteristics include the high elevation and harsh climatic conditions of the mine site area, the ubiquity of geochemically reactive gossanous materials throughout the mine site, and the pre-mine lack of soils and ecosystem development.

Because of these challenges, the general approach to reclamation planning for the mine has been to minimize surface disturbance through mine design and construction, and to then create post-mine topography and conditions that will achieve the matrix habitat end land use and support passive natural revegetation to the extent feasible. Key reclamation methods include recontouring to prevent barriers to movement of the target wildlife species and to create stable drainage features, and decompaction/scarification of potential growth media. Some limited additional measures are being investigated through the reclamation research program, discussed in Section 3.6 of Appendix 4-1.

Pre-development conditions and the approach to surficial materials use for reclamation within the Brucejack Mine site area and the M-243 portion of the transmission line are described in Appendix 4-1, Section 3. A key issue informing this approach is that overburden available as growth media within the mine site is predominantly PAG, with elevated element concentrations, particularly arsenic (Shaw and Simpson 2016) (Pretium 2020b, Appendix 3.3-1). This overburden is presently considered not suitable for use in reclamation and is instead recommended for handling in ways that will minimize potential for incremental acid rock drainage and metal leaching. It is not presently known if there are any areas within the mine site in which surficial materials may be amenable to active revegetation – this question is being investigated as part of reclamation research described in 2020 Mine Plan and Reclamation Program Update (Pretium 2020b) and initiated in 2021.

Until the reclamation research program is sufficiently advanced to resolve active revegetation areas and methodologies, the reclamation plan and associated reclamation liability costing assume that mine site disturbances will generally be recontoured, de-compacted as feasible, seeded with the Brucejack high elevation native species seed mix, and fertilized (i.e. to supplement passive natural revegetation).

4.3.2 Surficial Materials

Survey data indicate that soils and other surficial materials at the Brucejack Mine site are not suitable for use as reclamation growth media, and that overburden should not be spread as a reclamation cover but should be treated in a manner to minimize generation of acid rock drainage (Shaw and Simpson 2016). Although approximately 30,000 m^3 of this material was salvaged and stockpiled as required by EMLI, there is currently no plan to use these materials as reclamation covers pending results from ongoing reclamation research. Amendment of these materials, such as attempting to add neutralizing compounds, is not a feasible option. Vegetation cover pre-mine was limited and implementing measures such as enhancing soil size materials to promote plant growth is currently considered to pose a risk to local wildlife in that it may attract wildlife to consume vegetation with potential to contain elevated metals concentrations.

Shallow ripping will be conducted in areas of the mine site disturbance footprint as appropriate following decommissioning of structures to decompact surficial materials and facilitate any natural regeneration by native vegetation communities that may occur.

The northernmost 12.8 km of the Brucejack transmission line is comprised of clear spans over bedrock and ice dominated alpine terrain. Towers and lines were installed by helicopter. Towers are anchored in bedrock. Reclamation of this section of the transmission line at closure will entail removal of towers and conductor line.

The southern 6.7 km of the M-243 transmission line section was mostly forested pre-construction, however even here there are extensive areas of bedrock exposure or shallow growth media over bedrock, and most towers in this section are also anchored in bedrock. Trees were hand felled, and soils and surficial materials were not disturbed except at the tower sites due to tower construction using helicopter support. The small disturbed areas around tower sites with potential to support plant growth were seeded following transmission line construction. Following the removal of conductor and towers during mine closure, tower sites will be recontoured as feasible, including covering concrete foundations to the extent feasible. Any available growth media will be seeded with Pretium's elevation-specific native species seed mixture and fertilized to promote growth.

4.3.3 Landforms and Drainage

4.3.3.1 Pre-Mine Landforms and Drainage

The Brucejack Mine site is located in a bedrock controlled, high elevation area. Pre-mine, and in remaining undisturbed or minimally disturbed areas, the bedrock surface was/is irregular with rounded surfaces broken by crevices and depressions where snow accumulates. There were localized areas with shallow, slightly weathered overburden and limited areas with developed soil cover. Most of what is now the mine site drained to Brucejack Lake (now the WRTSF), with some areas draining to Camp Creek or directly to Brucejack Creek. Bedrock and shallow overburden extended to the lake shoreline, with few level areas.

4.3.3.2 Mine Operations Landforms, Water Management and Erosion Control

Mine construction required development of level pads (Figure 4.3-1**)** for surface infrastructure such as the mill and lower camp buildings. Parts of the pads were created by bedrock excavation; the remainder of the leveling was achieved by filling and compaction using excavated crushed rock sourced from the km 72 NPAG quarry. The pads are designed to be stable, and resulted in approximately 20 ha of level area being created on the site.

A contact water collection system was constructed to collect runoff from the mine site pads bedrock excavations as had been planned and permitted pre-mine because this bedrock is or is assumed PAG, and in accordance with the ML/ARD requirements of M-243 and the Brucejack ML/ARD Management Plan (Appendix 9-1-11).

Figure 4.3-1. Constructed Pads and Infrastructure Areas

4.3.3.3 Post-Mine Landforms and Drainage

Following the removal of the active portions of the contact water collection system, the camp pad will drain passively to Camp Creek and the slopes below the mill, along with a portion of the mill pad, will drain to lower Camp Creek or to Brucejack Creek. The remainder of the mill pad and the areas passively draining to the CWP during operations will drain to the CWP and from there to the WRTSF. The CWP will remain in place, with the spillway remaining intact, and allowed to spill passively via the current emergency spillway, to the WRTSF. All areas east of the operations contact water collection system that drained passively to the WRTSF during operations will continue to do so post-closure. Post-closure, much of the mine site will continue to drain to the WRTSF, which will continue to passively collect and settle sediment. The West Zone Pad area will continue to drain to Brucejack Creek post-closure.

4.3.3.4 Transmission Line

Transmission line construction entailed very minimal surface disturbance and no significant effects on landforms. Removal of the transmission line infrastructure at closure (towers, conductor and Knipple substation) will result in the post- transmission line landforms being almost identical to the pre-mining landscape. There will be very minor and localized terrain changes compared to pre-development at some tower sites, but these are mainly limited to the vegetated southern portion of the line and are expected to become obscured by vegetation over time. The Knipple substation pad will be left level, in approximately the same topographical condition as existed prior to Pretium's use of this site.

4.4 Reclamation and Closure Prescriptions

4.4.1 Sequence and Schedule

Brucejack Mine closure activities are planned for implementation in a sequential manner such that infrastructure needed to the end of mine closure remains in place and all other reclamation activities occur in a logical progression. Key infrastructure to remain in place until confirmed to no longer be necessary are the WTP and infrastructure required to support it, including power supply, emergency generators, housing for WTP operators and support personnel and transportation infrastructure.

Final closure is expected to take approximately three years, including approximately two years of closure and reclamation activities within the M-243 disturbance area (primarily the mine site area), and an additional year of closing and reclaiming off-site ancillary infrastructure outside of the M-243 permitted area (Table 4.4-1). The latter includes the southern Statutory ROW portion of the transmission line and closing and reclaiming the BJAR and adjacent camps and infrastructure from km 59 to the intersection of the BJAR and Highway 37.

Reclamation activities within this period are planned and designed to provide for long term stable landforms and site conditions, and acceptable post-closure water quality in the Brucejack Creek aquatic receiving environment downstream of the mine. Underground mine reclamation, including removal of underground mobile equipment and completion of other pre-flooding preparatory measures, and flooding will begin immediately following closure (Table 4.4-2). Removal of surface equipment, buildings and infrastructure not required for water treatment and ongoing reclamation activities will occur during the first summer season of the closure phase. Surface reclamation will then be conducted as described below, including recontouring to prevent barriers or hazards to wildlife, establishment of stable post-closure surface drainage, and decompaction as appropriate.

Table 4.4-1. Brucejack Mine Reclamation and Closure Schedule

	2029	2030	2031	2032	2033	2034	2035	2036	2037	2038	2039	2040	2041

Buildings & Equipment Removal																																																
Surface Reclamation																																																
Monitoring & Reporting																																																

**UG = underground mine*
**WT = water treatment

Mine flooding is estimated to be complete within seven months based on accelerated flooding accomplished by water withdrawal from the WRTSF; the withdrawal rate will be to the current licensed rate during the winter low flow period, and at accelerated rates during the freshet high flow period. Water treatment of the underground mine pool will continue throughout the active flooding period, predicted to be an additional eight months (total 15 months) [refer also to the Closure Underground Water Quality Adaptive Management Plan (Appendix 9-2-2)]. Watertight plugs will be installed in the WZ and VOK portals, and in the raise planned north of Brucejack Creek, during the first year of the closure phase to allow underground mine flooding to its ultimate flooding elevation. The mine equilibrium flooding elevation is predicted to be approximately 1404 masl (seasonal variation from 1394 to 1412 masl).

The WTP and related facilities will be removed when water treatment is no longer required. Mine openings to surface (portals and raises) will be sealed within the first two summer seasons of the closure phase, when access is no longer required. Remaining surface reclamation will be completed by the end of the second summer, along with removal of remaining surface infrastructure and equipment, including the transmission line. Monitoring and reporting will continue throughout the closure phase and for ten years following completion of site reclamation.

The Brucejack Mine site roads and the BJAR will be closed during the closure phase, therefore access for post-closure monitoring will be by helicopter. Post-closure monitoring will be carried out for site stability, surface and groundwater quality, aquatic resources, and reclamation success (including natural encroachment into facility areas by endemic vegetation). Geotechnical inspections will be conducted as required.

4.4.2 Mine Site Surface Reclamation

Mine reclamation at closure will begin with orderly and methodical removal of structures and equipment, except that required to support mine flooding and water treatment.

Most buildings and other infrastructure at the Brucejack Mine site are located on constructed pads (Table 4.4-3; Figure 4.3-1). The pads are stable, constructed with a combination of bedrock cuts (with excavated PAG surface material deposited into the WRTSF) and fill methods using NPAG quarried rock, or through placement of fill only. Off-pad facilities at the mine site include the upper camp area (including various offices and other, mostly modular, structures) CWP, site roads, contact water management infrastructure, overburden stockpile, WRTSF outlet weir, WRD, and the electrical services building and other structures located in the low lying area between the surface heavy shop and the Johnson Creek (East) diversion channel. Infrastructure within the upper camp area and warehouse and vicinity areas is mainly constructed on in-situ overburden, with several of these structures having been placed or constructed during advanced exploration or mine construction.

Table 4.4-3. Mine Site Constructed Pads and Infrastructure Areas.

Surface Infrastructure Pad	Area (ha)
Mill (including STPs) pad*	3.17
Lower camp pad*	2.39
VOK portal pad and storage *	1.01
Old heavy shop pad	0.60
Upper camp area (non-pad)	3.90
Upper camp bunk 6 pad*	1.04
Helipad and storage pads**	0.38
Main warehouse, electrical and waste sorting area	1.83
Diesel power station pad*	0.66
WZ portal pad**	2.31
Incinerator pad**	0.37
CWP	1.43
Truck shop pad	1.08
Total	**20.17**

*Combination cut and fill
**Fill only

Facilities pads within the mine site will be left in place at mine closure following removal of structures and equipment, with some recontouring of NPAG rock fill materials to reduce any potential for slumping and erosion and to support achievement of the end land use objective. In preparation for final reclamation, the mine site road surfaces, NPAG crushed rock cover on the pads, and low gradient areas near the Johnson Creek Diversion will be shallow ripped to reduce surface compaction, minimize surface erosion, allow for downward water infiltration, and create the conditions for such passive natural revegetation as may occur. Concrete pads will be covered with overburden and/or crushed rock from adjacent portions of infrastructure pads as feasible, dependent on materials availability. Culverts will be removed from the roads and cross-drains and water bars will be established to create stable drainage. Figure 4.4-1 summarizes mine site area surface reclamation treatments at closure.

Recontouring and decompaction work during closure will be aimed primarily at preventing hazards or barriers to wildlife movement to achieve the end land use objective of wildlife matrix habitat (movement areas) particularly for mountain goat, grizzly bear, and hoary marmot (M-243, Condition E.3). These animals will be able to move across the mine site post-closure to access foraging areas or other habitat that provides life requisites. Reclamation work during closure will be secondarily aimed, to the extent feasible and suitable, at creating conditions for passive revegetation via propagules from local endemic vegetation species in adjacent areas. The Brucejack reclamation liability costing includes seeding much of the mine site using Pretium's high elevation native seed mixture, however a passive reclamation approach is preferred.

Contact water management infrastructure will remain in place until surface water collection and treatment is no longer required, at which time ditches not required for post-closure water management will be backfilled, pipeline and pumping infrastructure will be removed, and manholes will either be removed or rendered inactive. The seepage collection weirs below the lower camp pad will be breached or removed. The CWP, which is constructed in bedrock, will remain in place and be allowed to spill passively via its spillway. The non-contact diversion channels will remain in place.

Name	Reclamation Treatment	Area (Ha)
Snow Dump	Very minor recontouring (<10% of area), decompact as feasible 5 to 10 cm max.	5.13
Incinerator Pad	Dozer (Excavator) recontouring, decompaction to 15cm as feasible.	0.37
Mine Site	Dozer (Excavator) recontouring, decompaction to 15cm as feasible.	26.50
Mine Site	Shallow (5 to 10 cm max) decompaction as feasible, minor pad edge recontouring.	2.74
VOK	Dozer (Excavator) recontouring, decompaction to 15cm as feasible.	4.44
Gossan Hill Exploration	Dozer (Excavator) recontouring, decompaction to 15cm as feasible.	2.29
BJAR	Dozer (Excavator) recontouring, decompaction to 15cm as feasible.	2.31
Proposed East WRD Access	Dozer (Excavator) recontouring, decompaction to 15cm as feasible.	1.12
Proposed Stockpile Sites	Dozer (Excavator) recontouring, decompaction to 15cm as feasible.	6.86

Legend

Reclamation Treatments

- Dozer (Excavator) recontouring, decompaction to 15cm as feasible.
- Shallow (5 to 10 cm max) decompaction as feasible, minor pad edge recontouring.
- Very minor recontouring (<10% of area), decompact as feasible 5 to 10 cm max.

Figure 4.4-1. Mine Site Surface Reclamation Treatments

Waste rock dump development is planned such that most PAG rock will be placed subaqueously in the WRTSF during mine operations. At mine closure, remaining sections of exposed PAG rock on the dump pad will be placed subaqueously in a retreat manner, such that there are shallow ponded areas over much of the pad and exposed NPAG rock on surface near the shore of the WRTSF.

4.4.3 Underground Mine

At closure, all underground tanks and their contents will be removed and their contents shipped off site for re-use or shipment to licensed facilities. Hydrocarbons and hazardous materials from fixed equipment that is not being removed will also removed for off site shipment to licensed facilities. Fixed underground equipment suitable for re-use will be removed and transported off site. All mobile equipment and supplies will be removed from the underground mine and shipped off site for re-use or disposal as appropriate.

Most stopes will be backfilled with waste rock and paste tailings during operations. Flooding and water treatment during mine closure will occur as described in the Closure Underground Water Quality Adaptive Management Plan (Appendix 9-2-2). At closure, the underground mine workings will be flooded over a period of approximately seven months. Water treatment of the underground mine pool is planned to continue for an additional eight months, for a total treatment duration of 15 months.

Both portals and the raise planned north of Brucejack Creek will be sealed with watertight plugs to enable the mine to flood to the predicted elevations. The portals and all raises will be sealed when no longer required for access. Any seepage from the plugs will be allowed to drain to Brucejack Creek / WRTSF.

4.4.4 Transmission Line

The Brucejack transmission line will remain in operation until this power supply is no longer required at the mine site; this is expected to follow the scheduled 15 months of closure phase water treatment. When no longer required, the Brucejack transmission line towers and conductor will be removed using helicopter support as necessary. Substation equipment and components will be removed using ground access. Transmission line and substation components will be transported off site for recycling or disposal as appropriate.

Within the southernmost 6.7 km section of the M-243 portion transmission line that is below the tree line, there may be some disturbance of surficial materials in the areas around the tower bases during the dismantling of the towers. Tower sites will be recontoured and concrete bases covered as feasible, and any growth media will be seeded with either the high or low elevation seed mixture, as appropriate. Removal of transmission line structures over most of the M-243 transmission line section is not expected to result in significant ground disturbance nor effects on landforms, as these are anchored in rock. Post- transmission line and tower removal, all portions of the transmission line are expected to meet the wildlife matrix habitat end land use objective.

4.5 Five Year Mine Reclamation Plan

Design of the Brucejack mine site has focused on efficient and essential use of surface disturbances. Due to the small, intensively used operations footprint, revegetation has not been possible to date within the mine's primary infrastructure area and there are no foreseeable opportunities for progressive

reclamation in the next five years beyond the small areas being used to support reclamation research. Almost all reclamation within the PMA will be completed during mine closure.

Outside of the primary infrastructure area, progressive reclamation of areas disturbed through surface exploration will continue. The surface exploration disturbance is much less intensive than within the primary facilities area, and extents within the PMA are very small as most exploration proximal to the mine is conducted underground.

4.6 Post-Closure Monitoring and Maintenance

4.6.1 Overview

Monitoring is required under Section 10.7.21 of the Code to demonstrate that reclamation and environmental protection objectives including land use, productivity, water quality, and stability of structures are being achieved (EMLI 2022). Mine closure is estimated to be completed within three years, followed by post-closure monitoring over the following ten years. The results of the monitoring program are to be included in the Annual Reclamation Report (per Section 10.4.4 of the Code).

The following is a description of conceptual post-closure monitoring plans planned for the Brucejack Mine. The length of time required for monitoring may be extended if the early results of the program indicate further monitoring is required. All facilities will be dismantled and/or removed from site during closure with site drainage and landforms contoured to a final closed state. As such, regular maintenance is not anticipated. Maintenance needs will be identified on an as-needed basis based on the monitoring and inspection programs described below.

Monitoring programs will be designed to address evolving needs and are anticipated to decrease in scope through the closure and post-closure periods. During the closure period, monitoring programs will focus on monitoring and management of reclamation activities. During the post-closure period, monitoring programs will focus on demonstrating reclamation success. The general scope of monitoring programs will include:

- Surface water quality and quantity, sediments, and aquatic biological resources;
- Groundwater quality and levels, including water chemistry and level in the underground mine as feasible;
- Structural integrity of portals and raise watertight plugs;
- Geotechnical assessment of post-mine landform and watercourse stability, including for the surface above the underground mine (subsidence); and
- Assessments of reclamation program success in meeting the end land use objectives.

Additional details are provided in the subsections below.

4.6.2 Surface Water Quality and Quantity, Sediments, and Aquatic Biological Resources

Surface water quality and quantity, sediments and aquatic biological resources monitoring and sampling will continue to follow the requirements of PE-107835 through the closure period, with the exception of the reference site (L3) and effluent discharges as these cease (first tailings, then mine water and CWP influents and WTP effluent once water treatment has concluded, and finally treated

domestic wastewater once the site has been fully closed). Once there is no longer a presence at the Brucejack site, surface water quality and quantity (flow) monitoring will continue twice per year (spring/fall) and sediments and aquatic biological sampling will be conducted once per year (fall) until the end of the first ten years of the post-closure period.

4.6.3 Groundwater

Monitoring of select groundwater wells pertinent to closure and post-closure monitoring will continue quarterly through the active closure period. The program will be reviewed prior to the end of closure and adjusted as appropriate with ENV and EMLI approval. It is expected that groundwater monitoring of a reduced number of groundwater wells will continue twice per year for the first ten years of the post-closure period.

The underground mine water level will be monitored as feasible during the course of flooding, and post-closure via the groundwater well monitoring program.

Post-closure groundwater monitoring will comprise both water level and water quality monitoring. Selected monitoring wells and the mine pool itself will be targeted for water quality monitoring. Biannual groundwater and mine pool sampling events are recommended in early June and late September, bookending the open water season. Dedicated dataloggers deployed at groundwater monitoring installations and in the mine pool will be downloaded during sampling events to provide a continuous record of water level data. In the case of the mine pool, loggers will also record electrical conductivity.

4.6.4 Mine Openings

The structural integrity of the watertight plugs in the WZ and VOK portals and the raise north of Brucejack Creek will be checked prior to placement of exterior seals at the end of the closure period to ensure these are performing as required and designed. Repairs will be carried out if and as needed.

4.6.5 Geotechnical

Geotechnical monitoring, inspection and assessment of post-mine landforms will continue annually during closure and the first ten years of post-closure. Implementation of the Subsidence Monitoring and Management Plan (Appendix 9-2-8) will continue through closure, and with a modified program appropriate to post-closure, and as approved by MEMPR, implemented during the first ten years of post-closure. The CWP and its spillway, and post-mine watercourses (particularly the two diversion channels) will continue to be inspected annually for structural integrity and performance. Post-mine, pads, decommissioned roads (including drainage crossings), the km 72 NPAG quarry, the WRD pad, and other post-mine landscape features will be inspected for stability and performance. Repairs will be carried out if and as needed.

4.6.6 Reclamation Program

Monitoring and assessments of the reclamation program success in meeting the end land use objectives will be conducted annually during the first ten years of post-closure. This will include monitoring for erosion, particularly any determined to affect surface water quality downstream of the WRTSF discharge, and remediation as appropriate. The mine site area will be inspected to confirm that closure measures implemented to achieve the end land use objective of matrix habitat remain

intact, with remedial measures implemented as appropriate as necessary. Natural locally endemic vegetation species encroachment onto the mine site will be monitored and documented.

4.6.7 Post-Closure Personnel Requirements and Access

Since regular maintenance is not anticipated post-closure, limited personnel are required. During the first-year post-closure, there will be 2 full time environmental project management leads. For subsequent years, the environmental project management leads time allocation will be reduced to 25%. During the ten years post-closure, additional support will be received from consultants. The environmental project management leads will be based offsite and helicopter transportation will be used for post-closure site access.

Post-closure monitoring will require personnel and access to site twice per year for surface water quality monitoring, twice during first ten years for sediment and aquatics Monitoring, quarterly for groundwater monitoring, and annually for mine openings, geotechnical, and reclamation Monitoring.

4.7 Reclamation Cost Estimate

The Reclamation Cost Estimate has been updated to the Newcrest cost model and to reflect all relevant changes described above (e.g. infrastructure and disturbance area changes since 2020 and maximum liability in the next five years). It is being submitted to the Chief Permitting Officer under separate cover as per Code Section 10.1.3(i).

5. MODELLING, MITIGATION, AND DISCHARGES

5.1 Summary

The proposed increase to Brucejack Mine's ore production rate will result in increased rates of underground waste rock excavation, waste rock deposition, and tailings discharged to the WRTSF. The influence of these increased rates and the associated chemical loadings on water quality discharged from the WRTSF to Brucejack Creek have been evaluated.

The following sections and the associated appendices present updated groundwater model results, water balance model results, and water quality model predictions which incorporate changes associated with Pretium's application to increase the authorized average ore production rate. Parameters of potential concern (POPC) were identified from the water quality model predictions. While some POPCs are expected to be mitigated by natural processes that are not accounted for in the water quality model, others are predicted to exceed the mine's current discharge limits or go above a water quality guideline. For these parameters of concern (POCs), a best achievable technology (BAT) assessment was carried out to evaluate treatment options, associated costs, and feasibility of implementation. The results of this assessment are presented in Section 5.6, and in the associated appendix. Potential risk to aquatic life from the modelled POCs was assessed in the water quality model report (Appendix 5-3) and is summarized in Chapter 6.

Taking into consideration the results of the BAT assessment and the effects assessment, Pretium is proposing to amend effluent permit 107835 to increase current discharge limits for nitrate and total arsenic (T-As), and to request the addition of discharge limits for dissolved copper (D-Cu) and total selenium (T-Se). Section 5.7 presents the requested discharge limits and the rationale for these proposed amendments.

5.2 Conceptual Site Model

The conceptual models used for Brucejack Mine are described in the groundwater model report (Appendix 5-1 – Section 2.9), the water balance model report (Appendix 5-2 – Section 3.1) and the water quality model report (Appendix 5-3 – Section 2 and Section 5.2).

5.3 Groundwater Model

The Brucejack mine groundwater model was updated to identify how the proposed increased production rate and associated mine plan would impact the groundwater system during operations and at closure. The groundwater model results are presented in Appendix 5-1, entitled *Brucejack Mine: 4950 tpd Groundwater Model Report.*

As compared to prior models based on the 3800 tpd production rate, the updated 4590 tpd groundwater model predicts increased inflow rates over LOM, but less overall groundwater extraction. The increased flows to the underground mine will be managed effectively by the mine's current water collection and treatment system. Predicted changes in baseflow reporting to Brucejack Creek for the 4950 tpd production rate are similar to those predicted for the 3800 tpd production rate. Contact groundwater flows to Brucejack Creek at closure are predicted to be higher than those predicted for the 3800 tpd mine plan on account of the slightly deeper and broader mine development. Groundwater

modeling results predicted for the 4950 tpd production rate have been incorporated into the site wide water balance and water quality models.

5.4 Water Balance Model

An updated water balance model based on the proposed increased production rate and associated mine plan was developed. The results of this model are presented in Appendix 5-2, entitled *Brucejack Mine: 4950 tpd Water Balance Model Report.* The water balance model forms the basis for the updated water quality predictions.

The water balance report highlights anticipated changes to mine site and receiving stream flows based on the increased mining rate for a Base Case scenario, representing average climate conditions. The report also considers water balance model sensitivities related to tailings solids content, variable climate conditions and climate change.

5.5 Water Quality Model

The Brucejack Mine water quality model has been updated to account for the increased ore production rate and the associated mine plan. Revisions to the model include the incorporation of revised flows from the updated water balance model, changes to the mine waste schedules, and updates to geochemical source terms based on new data and trends observed in the monitoring data sets. Base Case and Upper Case water quality predictions are presented for two stations: BJ 3.10, the mine's regulated discharge point, located at the outlet to the WRTSF; and BJ 2.62, a downstream monitoring location in Brucejack Creek. The Base Case is considered to represent a conservative expected case; whereas the Upper Case incorporates the combined effects of upper case geochemical source terms for all mine-related inputs.

The water quality model report, entitled Brucejack Mine: 4950 tpd Water Quality Model Report, is presented in Appendix 5-3. Water quality model predictions and the associated effects assessment presented in the report form the basis for the mitigation options presented in Section 5.6 and the requested revisions to the WRTSF discharge concentration limits described in Section 5.7.

Summaries of the maximum Base Case predicted concentrations for BJ 3.10 and BJ 2.62 are presented in Table 5.5-1 and Table 5.5-2, respectively, as compared to BC FWAL guidelines, current PE-107835 effluent discharge limits and previous model results under a 3800 tpd scenario. Parameters of potential concern were identified as parameters having Base Case predictions within 80% of a water quality benchmark (discharge limit or BC FWAL guideline). These are ammonia, nitrite, nitrate, sulfate, total arsenic, dissolved aluminum, dissolved copper, and total selenium. Additional consideration of these POPCs determined that biochemical reactions of ammonia, and chemical reactions of D-Al, and that occur in the WRTSF and are not captured by the mass balance water quality model, will maintain these parameters below the ammonia discharge limit and the D-Al FWAL guidelines. As well, additional consideration of modelled sulfate determined that sulfate is expected to remain below the FWAL guideline throughout the life of mine. An effects assessment was conducted on the model results for the remaining five parameters (nitrite, nitrate, total arsenic, dissolved copper and total selenium). The water quality model report presents an effects assessment for these parameters, which is summarized in Chapter 6. The effects assessment concludes that there is low risk of adverse effects to aquatic life in Brucejack Creek from modelled concentrations of these POCs, except for Upper Case T-Se during closure phase which had a moderate risk rating.

Table 5.5-1. Maximum Concentrations from the BJ 3.10 Base Case Water Quality Model, for All Mine Phases, Compared to the Maximum from Previous Model Updates, BC Water Quality Guidelines, PE-107835 Effluent Discharge Limits, and POPC Benchmarks.

Parameter	Units	Maximum Modelled			POPC benchmark	BC FWAL Guidelines		Effluent Discharge Limit

Notes: 2020 water quality model presented in the 2020 Update (Lorax 2020b)
2018 water quality model presented in the 3800 tpd Permit Amendment Application (Lorax 2018).
BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
POPC benchmark is equal to 80% of a discharge limit or 80% of a BC FWAL for parameters without discharge limits.
Bold font indicates parameters and concentrations that are greater than their POPC benchmark.
Concentrations that are higher in the current model than in both previous models are underlined.
Hardness dependent guidelines calculated using the baseline median hardness of 28 mg/L as $CaCO_3$.
Ammonia guidelines calculated using a pH of 8.0 and temperature of 15°C.
Copper guidelines calculated using the BC biotic ligand model. Inputs to the model were the 2019 annual averages measured at BJ 3.10 of pH 7.9, DOC 0.5 mg/L, Alkalinity 52 mg/L, Ca 24 mg/L, Mg 1.2 mg/L, Na 22 mg/L, K 7.7 mg/L, SO_4 46.5 mg/L, and Cl 1.6 mg/L. A summer temperature of 10 °C was used. The default of 10% of DOC present as humic acid was used.
Chromium guideline is for Cr(VI).
NP=none proposed.
NA=not applicable because the WQG is superseded by the discharge limit.

Table 5.5-2. Maximum Concentrations from the BJ 2.62 Base Case Water Quality Model, for All Mine Phases, Compared to the Maximum from Previous Model Updates, BC Water Quality Guidelines, PE-107835 Effluent Discharge Limits, and POPC Benchmarks.

Parameter	Units	Maximum Modelled			POPC benchmark	BC FWAL Guidelines		Effluent Discharge Limit

Notes: 2020 water quality model presented in the 2020 Update (Lorax 2020b)
2018 water quality model presented in the 3800 tpd Permit Amendment Application (Lorax 2018).
BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
POPC benchmark is equal to 80% of a discharge limit or 80% of a BC FWAL for parameters without discharge limits.
Bold font indicates parameters and concentrations that are greater than their POPC benchmark.
Concentrations that are higher in the current model than in both previous models are underlined.
Hardness dependent guidelines calculated using the baseline median hardness of 28 mg/L as $CaCO_3$.
Ammonia guidelines calculated using a pH of 8.0 and temperature of 15°C.
Copper guidelines calculated using the BC biotic ligand model. Inputs to the model were the 2019 annual averages measured at BJ 3.10 of pH 7.9, DOC 0.5 mg/L, Alkalinity 52 mg/L, Ca 24 mg/L, Mg 1.2 mg/L, Na 22 mg/L, K 7.7 mg/L, SO_4 46.5 mg/L, and Cl 1.6 mg/L. A summer temperature of 10 °C was used. The default of 10% of DOC present as humic acid was used.
Chromium guideline is for Cr(VI).
NP=none proposed.
NA=not applicable because the WQG is superseded by the discharge limit.

5.6 Mitigation Methods

Source control is the primary method that is used to maintain acceptable effluent quality at the Brucejack Mine's regulated discharge locations (the outlet of the WRTSF (BJ 3.10) as well as WTP and CWP effluent). Source control procedures developed for the mine are outlined in various environmental management plans (i.e., ML/ARD Management Plan (Appendix 9-1-11), Nitrogen Management Plan (Appendix 9-2-6), Chromium Management Plan (Appendix 9-2-1), as well as the WRTSF and WMP OMS documents (Appendices 9-1-17 and 9-1-18, respectively)). These management plans include sampling recommendations, management triggers, and corrective actions that are designed to minimize potential adverse effects to water quality. Monitoring of the various sources of contaminant loadings to the WRTSF, and monitoring of WRTSF effluent at BJ 3.10, show that the source control measures implemented have been effective in maintaining acceptable discharge quality. It is anticipated that these measures will continue to be effective for a production rate of 4950 tpd.

The section below (Section 5.6.1) describes the mine's current water treatment plant and its ability to manage the predicted flows and influent water quality associated with the increased production rate. Certain POPCs will be mitigated through natural processes occurring in the WRTSF (e.g., precipitation reactions, adsorption reactions, biologically mediated nitrification) or through different water management strategies as outlined in the Closure Underground Water Quality Adaptive Management Plan (Appendix 9-2-2). However, four parameters are predicted to go above current discharge limits or BC FWAL guidelines. A BAT assessment was carried out to evaluate additional treatment options. The results of this study are summarized in Section 5.6.2.

5.6.1 The Brucejack Mine Water Treatment Plant

5.6.1.1 Description

The WTP, located in the mill building, receives and treats underground mine water from mine dewatering, CWP water, and recycled process water from the mill. The WTP is designed to chemically precipitate targeted dissolved metals and remove influent TSS and the resultant chemical precipitates at influent flow rates of 3,120 to 10,000 m^3/day. Key components of the WTP treatment process include a pre-treatment clarifier (for coarse TSS removal), primary metal precipitation stage (dissolved metal and TSS removal), secondary metal precipitation stage (for dissolved metal oxy-anion and TSS removal), final metal polishing by filtration (for small particulate TSS removal) and final pH adjustment. A simplified schematic of the WTP process is shown in Figure 5.6-1.

Figure 5.6-1. Schematic of the Brucejack Mine clarifier and WTP treatment process (green boxes represent the WTP components)

The WTP generates a solid waste product (sludge) that requires management and disposal. The mass of the sludge produced depends on the TSS content of the influent, the chemical composition of the influent, the flow rate and the nature of the solid particles. Sludge is currently deposited in the WRTSF at a sludge to tailings mixing ratio not exceeding 2% sludge (dry weight) in accordance with PE-107835 and permit M-243.

The current WTP began operating in mid-2017 and ferric sulfate has been successfully used for metal removal in both metal precipitation stages since that time. The combined influent water quality has been monitored in the clarifier overflow since May 2018. Influent concentrations of most dissolved parameters targeted by treatment are below WTP effluent limits (*i.e*., Ag, Cd, Co, Cu, Fe, Pb, Mn and Zn), or are effectively treated with ferric sulfate (*i.e*., Al, As); therefore, sodium sulfide treatment has not been activated. The sulfide circuit can be commissioned for use if needed to meet PE-107835 discharge requirements. The WTP will continue operating into the closure phase, until active water treatment is no longer required.

5.6.1.2 Changes to Influent and Effluent Quality

The concentration of parameters targeted for treatment are predicted to increase through operations (Appendix 5-3), as are the WTP influent flows (Appendix 5-1). The WTP flows are modelled to increase as the mine void expands, stabilizing in 2025 at approximately 7,500 m^3/day (median value). The daily influent flows are modelled to peak at levels above the WTP design flow (10,000 m^3/day) for a few days in June of each year (up to 12,566 m^3/day) (Appendix 5-3). However, it is assumed that influent flows will be managed to remain within the WTP design specifications through the implementation of various water management strategies, including reduction of WTP influent flows from the underground or the CWP, and temporary storage of water in these facilities (the CWP is drawn down each spring prior to freshet). Additional measures could include allowing the CWP to discharge to the WRTSF if the water quality meets CWP effluent limits, or reducing inflows of recycled mill process water to the WTP.

Modelled WTP effluent quality is based on predicted influent quality and treatment removal rates derived from operational or proxy data sets. Parameter specific treatment removal rates, expressed as % removal are applied to the following parameters: D-Al (90% removal), D-As (90% removal), D-Cd (25% removal), D-Cu (95% removal), D-Mo (25% removal), D-Pb (75% removal), D-P (75% removal), D-Sb (50% removal), D-Se (25% removal), D-U (50% removal), D-V (75% removal), and D-Zn (25% removal). The same treatment removal rates are applied for the Base Case and Upper Case scenarios and are generally set at, or below, the operational removal efficiencies (as described in Section 3.5.2 of Appendix 5-3).

Treatment removal rates are unchanged from the previous 3800 tpd model (Lorax 2020b), with the exception of D-Cu. The calculated removal efficiency for D-Cu (73%) is bounded by low Cu concentrations in the influent (i.e., the maximum observed influent D-Cu concentration from 2018-2022 is 0.0031 mg/L). Observations of Cu removal at the Britannia Mine treatment plant, using a precipitation process that is comparable to the one used at Brucejack Mine, indicate removal efficiencies of 99.9% for Cu (Madsen, 2007). Therefore, based on operational and proxy data, the removal efficiency for Cu is conservatively modelled at 95% in the 4950 tpd model.

The predicted WTP influent concentrations are generally below the WTP design basis (Table 5.6-1), with the exception of Upper Case D-Pb, D-P and D-Ag. As compared to the 2018 and 2020 3800 tpd

models, the predicted WTP influent and effluent water quality for the 4950 tpd water quality model are generally comparable (Table 5.6-2). However, the 4950 tpd model predicts fewer parameters (n=3) exceeding WTP effluent discharge limits, and of those predicted to exceed, the concentrations are lower than the 2020 3800 tpd model.

The model conservatively assumes the iron precipitation process will be used throughout operations and closure. The sulfide precipitation process can achieve lower treatment levels and higher removal efficiencies for Cd, Cu, Ag and Zn, and will be activated by Pretium as needed to meet WTP effluent limits.

Table 5.6-1. Maximum Concentrations Predicted by the 2023 (4950 tpd) Water Quality Model for WTP Influent (Operations and Closure) Compared to the WTP Design Basis Concentrations

Parameter	Units	WTP Design Basis [1]	Maximum Modelled – WTP Influent (2023 Model)

* = parameter of potential concern at BJ 3.10.

5.6.2 Best Achievable Technology Assessment

A best achievable technology (BAT) assessment was conducted for water treatment at Brucejack Mine (Appendix 5-4). A BAT assessment is a site-specific evaluation of waste control technologies that have been proven in commercial application and whose risks are known, that accounts for site-specific operational, environmental, or geographic conditions and economic viability. Water quality modelling based on the mine plan for the proposed increased production rate predicts that concentrations of certain parameters will go above the current water quality discharge limits or BC FWAL guidelines at monitoring station BJ 3.10 during the operations phase. Therefore, the purpose of the BAT assessment is to evaluate options for water treatment at the outlet of the WRTSF to meet current discharge limits and applicable water quality guidelines at BJ 3.10 during the operations phase, under the proposed increased production rate scenario.

The WRTSF outlet is characterized by high volumes and relatively low concentrations, which poses a challenge for treatment. In general, it would be preferable to treat lower volumes of more concentrated sources upstream of the WRTSF outlet; however, the primary sources of POCs during operations at BJ 3.10 (i.e., NO_3, T-Se, D-Cu and T-As) are tailings and waste rock deposited in the WRTSF. Therefore, opportunities to treat the sources of POCs upstream of the WRTSF outlet are limited.

The BAT assessment has been conducted in accordance with the step-by-step process described in the ENV guidance document titled *Best Achievable Technology Assessment to Inform Waste Discharge Standards Handout*, published in October 2021. Treatment technologies for POCs were identified and evaluated for feasibility, reliability, control-effectiveness, and cost-effectiveness. The BAT assessment concluded that the low effluent limits for T-Se and D-Cu require the use of reverse osmosis (RO) technology, and RO is a robust treatment solution for NO_3 and T-As as well. Therefore, RO is considered best achievable technology to meet the current discharge criteria for all POCs during operations, based on the flows and water quality predicted for WRTSF discharge under the proposed increased production scenario. Based on treatment vendor engagement, the capital cost for a prefabricated RO-based system is expected to be approximately $73,000,000 CAD, assuming a design flow rate of 5,760 m^3/hr. The annual operating cost for the system is expected to be approximately $27,500,000 CAD per year.

While not addressed directly in the BAT assessment, it is preferable to limit the use of hazardous chemicals/reagents where possible. Health and safety considerations will be required in any subsequent feasibility assessment, including potential impacts to the mine's operational health and safety program, per the Health, Safety and Reclamation Code for Mines in British Columbia (EMLI, 2022). These considerations may include, but not be limited to:

- Chemical/reagent types and quantities required;
- Chemical/reagent transport and storage requirements for protection of human health and the environment;
- Risk management and mitigation measures associated with chemical/reagents, such as spill response, engineered and personal protective equipment, and dose delivery mechanisms; and
- Safe access to treatment facilities through operations and closure, given the geohazards and remote location of the Brucejack Mine site.

Based on the selected BAT (i.e., an RO-based system), treatment of the high flow rates expected at the WRTSF outlet would require an impractically large footprint and high energy demand. Further, the RO process generates a waste stream highly concentrated in contaminants (among other residuals, such as filter backwash), which will require management and additional treatment, resulting in additional operational complexity and cost. The estimated capital and operating costs of a WRTSF treatment system (with the capacity to treat approximately 50% of predicted peak flows) are approximately $73,000,000 CAD and $27,500,000 CAD/year, respectively. Therefore, treatment of the WRTSF is considered impractical and uneconomical. In lieu of treatment at the WRTSF outlet, new or increased BJ 3.10 discharge limits for POCs are proposed in the following section.

5.7 Proposed Effluent Permit 107835 Amendments

5.7.1 Introduction

Condition 1.1.1 of PE-107835, last amended June 16, 2022, specifies discharge limits applicable at the outlet to the WRTSF (station BJ 3.10) (Table 5.7-1). Because most of the flow in Brucejack Creek comes from the WRTSF, the discharge limits that Pretium has applied for are intended to be protective of aquatic life in Brucejack Creek without dilution. Discharge limits for T-Fe and T-Ag were applied for as part of the original application for *Mines Act* and *Environmental Management Act* permits (see Appendix 5.5-1 which is a copy of Appendix 7-Z of the 2015 MA/EMA application). The rationale for the T-Fe and T-Ag limits was that baseline monitoring showed that these parameters were occasionally naturally elevated in Brucejack Creek to concentrations greater than BC FWAL guidelines. The discharge limits for T-Fe and T-Ag in PE-107835 are the 95th percentiles of baseline monitoring results at BJ 2.62 from 2009 to 2013. Discharge limits for nitrate, nitrite, ammonia, T-Sb, and T-As were based on water quality model results and an effects assessment that concluded that the maximum modelled concentrations at BJ 3.10 have low risk of causing adverse effects to aquatic life in Brucejack Creek (Appendix 5.5-2 is PE-107835 Amendment Application #4 which includes the derivation of the nitrate and nitrite discharge limits; Appendix 5.5-3 is the Water Quality Model Report for the 3800 tpd Amendment Application which includes the derivation of the ammonia, T-Sb, and T-As discharge limits). The discharge limits for TSS and pH were not applied for by Pretium. Presumably these limits are standard conditions in mine effluent permits. The TSS limits are equal to limits specified by federal Metal and Diamond Mine Effluent Regulations.

Pretium is applying to increase the discharge limits for nitrate and arsenic, and to add new discharge limits for copper and selenium. The rationale for these amendments is described in the following sections and the application forms for these proposed amendments are provided in Appendix 5-6. Pretium is also applying to amend the Authorized Works in PE-107835 from three to four sewage treatment plant units to allow for redundancy, but no change to the permitted daily rate of discharge of treated STP effluent is being requested (Appendix 5.6).

Table 5.7-1. Current BJ 3.10 PE-107835 discharge limits and their associated derivation method, and application

Parameter	Maximum	Units	Derivation Method	Application
Total Suspended Solids	30 (maximum) 15 (monthly average)	mg-/L	Included in original permit issued in 2015	Pretium did not apply for TSS discharge limit
pH	6.5-8.5	pH	Included in original permit issued in 2015	Pretium did not apply for pH discharge limit
Nitrite	0.24	mg-N/L	Upper Case model	Effluent permit amendment #4 Nov 14, 2016
Nitrate	11.5	mg-N/L	Upper Case model	Effluent permit amendment #4 Nov 14, 2016
Ammonia	4.0	mg-N/L	Upper Case model	3800 tpd permit amendment March 2018
T-Sb	28	µg/L	Upper Case model	3800 tpd permit amendment March 2018

5.7.2 Proposed Amendment to Nitrate Discharge Limit

A change to Condition 1.1.1 of PE-107835 is being applied for to increase the maximum authorized nitrate concentration in discharge from the WRTSF from 11.5 mg-N/L to 20 mg-N/L (Table 5.7-2).

Table 5.7-2. Proposed Amendment: Condition 1.1.1 – Cumulative Compliance Requirements (Nitrate)

Parameter	Units	Current Maximum	Requested Amended Maximum
Nitrate	mg-N/L	11.5	20

Water quality model results for the 4950 tpd mine plan indicate that nitrate concentration at BJ 3.10 will exceed the current discharge limit of 11.5 mg-N/L. The Base Case model has monthly average nitrate predictions of up to 15 mg-N/L. The Upper Case model has monthly average nitrate predictions of up to 28 mg-N/L (Appendix 5.3). An ecological effects assessment concluded that 28 mg-N/L nitrate will have a low risk of causing adverse effects to aquatic life in Brucejack Creek. This conclusion was supported by site-specific toxicity testing using species representative of aquatic life in Brucejack Creek which found that the maximum modelled concentration was half of the lowest chronic endpoint (IC20 of 54.1 mg-N/L for *Ceriodaphnia dubia*). The effects assessment also concluded that risk of eutrophication from higher nitrate levels in Brucejack Creek is low because algal growth will continue to be limited by the low phosphorus levels in the stream. A discharge limit of 20 mg/L is being applied for, even though WRTSF nitrate levels have the potential to increase to 28 mg-N/L, because 20 mg-N/L will ensure that discharge from the WRTSF does not cause nitrate levels in upper Sulphurets Creek to increase above the long-term BC FWAL guideline of 3 mg-N/L, even during low flow months with minimal mixing of Brucejack Creek with Sulphurets Creek water.

5.7.3 Proposed Amendment to Arsenic Discharge Limit

A change to Condition 1.1.1 of PE-107835 is being applied for to increase the maximum authorized T-As concentration in discharge from the WRTSF from 10 µg/L to 26 µg/L (Table 5.7-3).

Table 5.7-3. Proposed Amendment: Condition 1.1.1 – Cumulative Compliance Requirements (Arsenic)

Parameter	Units	Current Maximum	Requested Amended Maximum
T-As	µg/L	10	26

Water quality model results for the 4950 tpd mine plan indicate that T-As concentration at BJ 3.10 will exceed the current discharge limit of 10 µg/L. The Base Case model has monthly average T-As predictions of up to 14 µg/L. The Upper Case model has monthly average T-As predictions of up to 26 µg/L (Appendix 5-3). An ecological effects assessment concluded that 26 µg/L T-As will have a low risk of causing adverse effects to aquatic life in Brucejack Creek. This conclusion was supported by site-specific toxicity testing of an algae species (*Pseudokirchneriella subcapitata*) that is known to be sensitive to chronic toxicity from arsenic and is representative of aquatic life present in Brucejack Creek. The proposed discharge limit is less than half the IC20 for growth (70 µg/L) from three *P. subcapitata* toxicity tests conducted using BJ 3.10 water. A discharge limit of 26 µg/L will not cause T-As levels in upper Sulphurets Creek to increase above the long-term BC FWAL guideline of 5 µg/L during low flow months. During high flow months, T-As concentration in upper Sulphurets Creek is naturally greater than the BC FWAL guideline due to the effects of glacial melt on water quality in upper Sulphurets Creek.

5.7.4 Proposed Amendment to Add a Copper Discharge Limit

A change to Condition 1.1.1 of PE-107835 is being applied for to add a maximum discharge limit of 0.9 µg/L dissolved copper in the discharge from the WRTSF (Table 5.7-4).

Table 5.7-4. Proposed Amendment: Condition 1.1.1 – Cumulative Compliance Requirements (Copper)

Parameter	Units	Current Maximum	Requested Amended Maximum
D-Cu	µg/L	There is currently no discharge limit for dissolved copper	0.9

Water quality model results for the 4950 tpd mine plan indicate that D-Cu concentrations at the WRTSF outlet during the operations phase will be higher than the typical long-term BC FWAL guideline of 0.3 µg/L (based on typical hardness, pH, and dissolved organic carbon at BJ 3.10). The Base Case model predicts D-Cu will increase to 0.42 µg/L at the end of operations (Appendix 5-3). The Upper-Case model results are up to 0.87 µg/L. An ecological effects assessment concluded that 0.9 µg/L D-Cu will have a low risk of causing adverse effects to aquatic life in Brucejack Creek. This conclusion was supported by site-specific toxicity testing. The proposed discharge limit is less than half the lowest IC20 (2.3 µg/L) from four toxicity tests conducted using BJ 3.10 water. The geographic extent of changes to D-Cu concentration from a discharge limit of 0.9 µg/L are considered localized to Brucejack

Creek, because D-Cu concentrations are typically greater than 0.9 µg/L at site SC0 in upper Sulphurets Creek (average of 4.2 µg/L from quarterly monitoring conducted from 2015 through 2021).

5.7.5 Proposed Amendment to Add a Selenium Discharge Limit

A change to Condition 1.1.1 of PE-107835 is being applied for to add a maximum discharge limit of 6.2 µg/L total selenium in the discharge from the WRTSF (Table 5.7-5).

Table 5.7-5. Proposed Amendment: Condition 1.1.1 – Cumulative Compliance Requirements (Selenium)

Parameter	Units	Current Maximum	Requested Amended Maximum
T-Se	µg/L	There is currently no discharge limit for total selenium	6.2

Water quality model results for the 4950 tpd mine plan indicate that T-Se concentrations at the WRTSF outlet during the operations phase will be higher than the BC FWAL guideline of 2 µg/L. The Base Case model predicts T-Se will increase to 2.1 µg/L towards the end of operations (Appendix 5-3). The Upper-Case model predictions are up to 6.2 µg/L. An ecological effects assessment concluded that 6.2 µg/L T-Se will have a low risk of causing adverse effects to aquatic life in Brucejack Creek. A discharge limit of 6.2 µg/L will not cause concentrations at SC0 to increase to greater than the BC FWAL guideline.

5.8 Initial Dilution Zone

The Brucejack Mine WRTSF is the headwater to Brucejack Creek (i.e., the receiving environment) and thus an initial dilution zone is not defined for WRTSF discharge. The current discharge limits and the proposed discharge limits were developed to be protective of aquatic life in Brucejack Creek without dilution (see Section 5.7.1).

5.9 Discharge Management

Discharge quality from the WRTSF is managed through source control and through treatment of contact water by the WTP and treatment of sewage by the STPs. Mine site water management has effectively maintained WRTSF effluent quality, measured at site BJ 3.10, below discharge limits in PE-107835 or below FWAL guidelines for parameters without discharge limits.

BJ 3.10 water quality is sampled weekly, in accordance with PE-107835. Results are typically received from the analytical laboratory (ALS Environmental) within 2 weeks of the sample date. Pretium staff review BJ 3.10 water quality results when received from the analytical laboratory and if any results are above discharge limits, notifications are provided in accordance with condition 5.3 of PE-107835. A result that is above a discharge limit is investigated to determine the probable cause, and to determine and implement remedial actions, if necessary, to prevent similar non-compliance in the future.

BJ 3.10 water quality results are evaluated by Pretium staff to identify POPCs, and to determine if additional measures are required to manage POPCs, using a trigger response plan (TRP) (Figure 5.9-1).

Step 1 of the TRP is to identify parameters that have concentrations greater than a trigger value. Trigger values at BJ 3.10 are set using criteria for defining POPCs (ENV, 2019). Trigger concentrations are equal to 80% of an applicable threshold, either the discharge limit in PE-107835 or

BC FWAL guidelines for parameters without discharge limits. Each weekly effluent sample is compared to trigger values based on discharge limits or short-term FWAL guidelines. Trigger values based on long-term FWAL guidelines are compared to the average concentration from the previous five weekly samples. If a BJ 3.10 result is less than a trigger value, routine monitoring is continued. If a result is greater than a trigger value, Step 2 is carried out.

Step 2 of the TRP is to assess whether a concentration is consistently greater than a trigger value. This is done by collecting a new BJ 3.10 sample as soon as possible and requesting rush analysis from the analytical laboratory. If a subsequent sample has already been collected, since BJ 3.10 is sampled weekly and ALS can take more than a week to issue reports, then ALS will be requested to rush the analyses of the most recent BJ 3.10 sample. If the follow-up sample concentration is below the trigger level, routine monitoring resumes. If the follow up sample is also greater than the trigger value, Step 3 is carried out.

Step 3 of the TRP involves examining recent BJ 3.10 monitoring results in comparison to historic levels and to expected concentrations based on the Brucejack water quality model. Also, recent concentrations and flows from the various sources to the WRTSF are assessed relative to the long-term monitoring datasets to identify if any sources have unusually high loadings to the WRTSF. If it is determined that the monitoring results are in line with expected water quality and are unlikely to increase to concentrations that are above a FWAL guideline or exceed a discharge limit, then routine monitoring is resumed. If the review of water quality trends at BJ 3.10 and of source loadings determines that a POPC concentration could increase to a value greater than a FWAL guideline or discharge limit, then Step 4 is carried out.

Step 4 of the TRP involves the design and implementation of actions to prevent concentrations reaching levels that are potentially harmful to the receiving environment. This will typically involve additional monitoring at BJ 3.10 and sources to the WRTSF to better understand the cause of the unanticipated water quality trend. If the monitoring results indicate that additional source control measures could reduce concentrations at BJ 3.10, they will be implemented if achievable. An effects assessment will be conducted to determine the risk to aquatic life in Brucejack Creek if concentrations increase to greater than the FWAL guideline or discharge limit. The results of the effects assessment will be used to determine whether management actions and/or regulatory tools will be needed. An example of a management action would be a process implemented to reduce loadings to the WRTSF or to reduce the concentration in the WRTSF discharge. An example of a regulatory tool is an application for a discharge limit that is greater than the FWAL guideline or existing discharge limit and is protective of aquatic life in Brucejack Creek.

Figure 5.9-1. Trigger Response Plan flowchart for water quality at BJ 3.10

6. ENVIRONMENTAL ASSESSMENT PREDICTIONS

6.1 Introduction

The Brucejack Mine water quality model has been updated to account for the proposed increased ore production rate and the associated mine plan, as described in Section 5.3. Water quality was modelled at two sites in Brucejack Creek: site BJ 3.10, located at the outlet of the WRTSF, and at site BJ 2.62, located approximately 500 m downstream of BJ 3.10. BJ 2.62 represents the maximum modelled concentrations during closure and post-closure because all loadings from the flooded underground mine are modelled to flow to site BJ 2.62. The Base Case water quality model is considered an expected case; whereas the Upper Case incorporates the combined effects of upper-case geochemical source terms for all inputs and is considered a potential but unlikely scenario.

Water quality model results were screened to identify parameters of potential concern to aquatic life in the receiving environment. POPCs were identified as parameters that had a Base Case model result that was greater than 80% of a water quality benchmark (either a discharge limit or a BC FWAL guideline for parameters that do not have discharge limits) during any mine phase, as described in the BC Ministry of Environment and Climate Change Strategy's fact sheet on parameters of concern (ENV, 2019b). Concentrations that are below these benchmarks are considered protective of aquatic life in the receiving environment because discharge limits were developed to be protective of aquatic life without dilution in the receiving environment.

The screening of water quality model results identified eight POPCs: ammonia, nitrite, nitrate, sulfate, total arsenic, dissolved aluminum, dissolved copper, and total selenium. These POPCs were then evaluated to determine if there are reasons to exclude them from further assessment. Ammonia was excluded from further assessment because it was determined that denitrification in the WRTSF will convert ammonia to nitrate resulting in ammonia levels well below its discharge limit. Denitrification is a biochemical process that was not included in the mass balance water quality model. Dissolved aluminum was excluded from further assessment because it was determined that solubility constraints result in the precipitation of D-Al in the WRTSF, which reduces the concentration of D-Al at the WRTSF outlet to below its POPC benchmark. Sulfate was excluded from further assessment because the Base Case model results are less than the long-term BC FWAL guideline during all mine phases, when the sulfate guideline is calculated using the modelled hardness, instead of the baseline hardness of 28 mg/L used for calculating the POPC screening benchmark for sulfate.

A residual effects assessment was conducted on the remaining five parameters of concern (POCs). Details of water quality modelling and the effects assessment are presented in Appendix 5-3. Results of the residual effects assessment are summarized below.

6.2 Contaminant Transport

Contaminants transport from mine sources to aquatic life, terrestrial life, and to humans was considered as part of the residual effects assessment (Figure 6.2-1). Brucejack Creek is not used as a drinking water source for people working at the mine, and it is very unlikely that it will be used as a drinking water source in the future due to its remote location. Terrestrial wildlife have the opportunity to use Brucejack Creek as a source of drinking water from approximately July through October, when the stream is ice free. Observations of terrestrial wildlife during baseline studies (Rescan, 2013b;

Rescan, 2013i) and during mine construction and operation periods (incidental wildlife observations are recorded by mine staff and reported in Annual Reports for Permits M-243, PE-107835, and PA-107025) indicate that wildlife will infrequently use Brucejack Creek as a drinking water source: therefore, the effects assessment focused on aquatic life as the most likely receptor for potential adverse effects from changes to water quality. Brucejack Creek is non-fish-bearing and is not considered fish habitat because the closest fish-bearing waterbody is the mouth of Sulphurets Creek, more than 20 km downstream of Brucejack Creek. Therefore, the assessment endpoint of the effects assessment was the potential for modelled water quality in Brucejack Creek to cause toxicity to benthic invertebrates and periphyton inhabiting the stream. The potential for modelled nutrient concentrations (nitrogen and phosphorus) to cause eutrophication was also assessed. The potential for modelled selenium concentrations to cause adverse effects to waterbirds was also assessed.

Figure 6.2-1. Conceptual site model of contaminant transport to receptors.

6.3 Effects Assessment Results

The residual effects assessment considered the ecological context of the receiving environment; the geographic extent over which the modelled concentrations of POCs could be above a water quality benchmark; the magnitude, duration, and frequency of model results that are above water quality benchmarks; the reversibility of changes to water quality after mine closure; and the resiliency of the aquatic community if changes to water quality caused adverse effects. These components of the effects assessment were used to derive a determination of risk to aquatic life from the modelled concentrations of POCs.

The risk to aquatic life from the maximum Base Case model result was determined to be low for all five POCs during all mine phases (Table 6.3-1). The risk to aquatic life from the maximum Upper

Case model result was determined to be low for all five POCs during all mine phases except for selenium during the closure phase which was rated as moderate (Table 6.3-1).

Table 6.3-1. Summary of Risk Ratings for Base Case and Upper Case Modelled Concentrations of Parameters of Concern.

	Base Case			Upper Case		
	Operations	Closure	Post-closure	Operations	Closure	Post-closure
Nitrate (eutrophication)	low	low	low	low	low	low
Nitrate (toxicity)	low	low	low	low	low	low
Nitrite	low	low	low	low	low	low
Total arsenic	low	low	low	low	low	low
Dissolved copper	low	low	low	low	low	low
Total selenium	low	low	low	low	moderate	low

Selenium was the only parameter with a risk rating that wasn't low, and only for the Upper-Case model during the closure phase. The Upper-Case model uses the upper case loadings of Se from all mine sources, and is considered unlikely to occur. Monitoring results from BJ 3.10 and BJ 2.62 support the conclusion that selenium concentrations in Brucejack Creek are best represented by the Base Case model and that the Upper-Case model is an overestimate of potential selenium levels (Figure 6.3-1). This indicates that Se concentrations in Brucejack Creek are likely to remain below, or slightly above, the BC FWAL guideline during operations. As well, water management strategies described in the Brucejack Closure Underground Water Quality Adaptive Management Plan (Appendix 9-2-2), which weren't modelled in the Base Case and Upper-Case water quality model scenarios, can be implemented to reduce Se concentrations during closure.

Figure 6.3-1. Modelled total selenium concentrations at BJ 3.10 (top) and BJ 2.62 (bottom) compared to the BC FWAL guideline and to measured concentrations.

The selenium effects assessment (section 5.13 of Appendix 5.3) also shows that there are few receptors in the Brucejack Creek catchment that are potentially sensitive to elevated Se levels. It is generally thought that algae and invertebrates are tolerant of elevated Se concentrations, and the more important role of these organisms is the transfer of Se to egg-laying vertebrates (fish, amphibians, or waterbirds). Potential adverse effects to egg-laying vertebrates feeding on a high Se diet include reduced hatchability of eggs and defects in hatchlings. There are no fish or amphibians present in the Brucejack Creek catchment; therefore, potential receptors are the few waterbirds which have been observed around Brucejack Creek. Aquatic bird species that have been recorded that may feed on invertebrates in Brucejack Creek are a sandpiper species and semipalmated plover (ERM, 2022a included as Appendix F to Appendix 5-3, the water quality model report), which are not listed by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC) or the British Columbia Conservation Data Centre.

In summary, the maximum modelled concentrations of parameters of concern were evaluated to have low risk of causing adverse effects to aquatic life in Brucejack Creek, with the exception of Upper-Case modelled selenium concentrations during closure, which were evaluated to have a moderate risk of causing adverse effects to nesting birds that primarily feed on insects in Brucejack Creek, if any occur. It is likely that water can be managed during closure to reduce the peak concentrations that occur in the model when water from the flooded underground mine flows to Brucejack Creek.

Adverse effects to human health are not expected because Brucejack Creek water is not used as a drinking water source for humans. Brucejack Creek flows into Sulphurets Creek. There is a minimum mixing ratio of 6:1 (part Sulphurets Creek to Brucejack Creek) at upper Sulphurets Creek sites, and typically higher mixing ratios (ERM, 2017; included as Appendix B to the Appendix 5-3 (the water quality model report)). This level of mixing will produce concentrations in upper Sulphurets Creek at SC0 that are below BC drinking water guidelines, except for parameters that are naturally elevated at SC0 to concentrations that are above drinking water guidelines.

7. ENVIRONMENTAL MONITORING

7.1 Environmental Monitoring Program Design

Pretium implements an extensive environmental monitoring program at and in the vicinity of the Brucejack Mine site in accordance with the monitoring requirements of the mine's authorizations (e.g. EAC M15-01, CEAA 2012 Decision Statement, M-243, PE-107836, PA-107025, various *Water Sustainability Act* (*WSA*) and Northern Health authorizations) and component management plans of its EMS. The Brucejack Mine EMS includes 21 component management plans required under Schedule B of EAC #M15-01 and the 10 additional management plans required through other Provincial authorizations (mainly M-243, PE-107835 and PA-107025). These management plans are discussed in Chapter 9 and provided in Appendices 9-1 and 9-2. The proposed production rate increase is not expected to require changes to existing environmental monitoring programs.

Brucejack Mine effluent quality related monitoring programs have been designed and are implemented for all deposits and effluents to the WRTSF, as well as for the downstream aquatic receiving environment in accordance with the conditions of Permit M-243 and PE-107835 (Appendix 1-1). Key objectives of these effluent quality specific monitoring programs relate to the implementation and effectiveness of the mine's source control measures. Source control is the primary means by which acceptable effluent quality is maintained at the Brucejack Mine's regulated discharge locations [i.e. the outlet to the WRTSF (monitoring site BJ 3.10) and WTP and CWP effluent]. Source control measures include both mine infrastructure design (e.g. water management and water treatment infrastructure) and management procedures.

Specifically, the Brucejack Mine effluent quality environmental monitoring program is designed to:

- Verify that source control measures are being implemented as planned;
- Confirm the effectiveness of the source control measures, including that if monitoring of effluent management performance (e.g. effluent quality compared to PE-107835 effluent discharge limits) and/or receiving environment condition (results of aquatic effects monitoring in aquatic receiving environment) identifies measures are insufficiently effective, follow-up is initiated to address this;
- Specifically for ML/ARD, provide early warning of the potential onset of ML/ARD and the magnitude of any environmental effects, and verify source terms used in the water quality model, and associated water quality predictions;
- Provide monitoring data for inputs to the water quality model that is used to update predictions of BJ 3.10 discharge water quality (e.g. data for geochemical source terms, such as contact water from the underground mine which represents the cumulative geochemical load of wall rock, groundwater, paste backfill and rockfill in the underground mine workings as described in Appendix 5-3 Section 3.4.3) (refer to Section 5.5);
- Monitor flows and water quality at specified locations upstream, at and downstream of the regulated discharges (WTP and site BJ 3.10) to verify compliance with PE-107835; and
- Monitor sediments and aquatic biological indicators at and downstream of site BJ 3.10, and a reference site location to provide a basis for assessing potential aquatic biological effects of the mine's effluent discharge on the aquatic receiving environment.

Source control procedures developed for the Brucejack Mine are outlined in the following environmental management plans: ML/ARD Management Plan, Nitrogen Management Plan, Chromium Management Plan, WRTSF OMS Manual, and Water Management Plan OMS Manual). These plans, which are summarized in Chapter 9 and provided in Appendices 9-1 and 9-2, include sampling programs, management triggers, and corrective actions that are designed to minimize potential adverse effects to water quality.

As described in Section 5.6, monitoring of the various sources of contaminant loadings to the WRTSF, and monitoring of WRTSF effluent at BJ 3.10, shows that the source control measures implemented have been effective in maintaining acceptable discharge quality. It is anticipated that these measures will continue to be effective for a production rate of 4950 tpd.

7.2 Mine Site and Discharge Water Monitoring Program

7.2.1 Overview

The Brucejack Mine site water monitoring program, including the mine's regulated final effluent discharge point site BJ 3.10, is specified by M-243 and PE-107835 (Appendix 1-1) and associated management plans specific to the mine site. The associated management plans, including management plans to provide water quality management via mine waste management and other source control measures, are the ML/ARD Management Plan (Appendix 9-1-11), Nitrogen Management Plan (Appendix 9-2-6), Chromium Management Plan (Appendix 9-2-1), Water Management Plan – OMS Manual (Appendix 9-1-18) and Waste Rock and Tailings Storage Facility – OMS Manual (Appendix 9-1-17). These permits and management plans have established/confirmed monitoring site locations, sampling frequency, parameters for assessment, sampling and analytical laboratory methodologies, QA/QC programs, and reporting requirements. Monitoring programs are based on and conform to methods and requirements of the following relevant published ENV and EMLI guidance/requirements documents:

- Water and Air Baseline Monitoring Guidance Document
- British Columbia Field Sampling Manual
- Environmental Data Quality Assurance Regulation (EMA)
- British Columbia Environmental Laboratory Manual

7.2.2 Groundwater

The Brucejack Mine groundwater system has been characterized through several hydrogeological field investigations which have established a broad monitoring well network within and proximal to the mine. The current monitoring network is comprised of 31 monitoring wells as prescribed by Appendix B of Effluent Permit PE-107835 (Appendix 1-1) [BJ-GW18-22A was destroyed in 2022, and was replaced with a vibrating wire piezometer in 2023 (New Well @P2)]. Four additional monitoring wells are monitored outside of permit requirements. Permit-required monitoring well locations are shown in Figure 2.6-6 and monitoring intervals and frequency are listed in Table 7.2-1. Monitoring wells are situated broadly about the mine and located within the M-243 PMA boundary, with exception of one well pair. The groundwater monitoring network characterizes groundwater system response to mining of the VOK and West Zone and operation of the CWP and WRTSF. The one well pair located outside

of the M-243 PMA boundary, BJ-GW14-14A/B, was constructed during a 2014 potable water source investigation (BGC 2014c).

Hydraulic head and groundwater quality sampling are undertaken on a shifted quarter (sQ) or biannual basis, as specified by PE-107835. Shifted quarters are off-set from calendar quarters by one month. This offset allows for evaluation of groundwater quality that coincides with seasonal controls (*e.g.,* freshet, first snowfall). Continuous groundwater level data is collected using dataloggers programmed on a six-hour frequency. The data are compensated for barometric pressure changes and georeferenced to manual water level readings collected on a quarterly basis.

Samples are collected, preserved, stored, transported and tested in accordance with the requirements set forth in the British Columbia Environmental Laboratory Manual (Austin 2015) and the British Columbia Field Sampling Manual (Clark 2013). Groundwater quality samples are collected using low flow sampling methods whereby samples are collected when the well water level and field parameters (measured via flow-through cell and multi-parameter probe) stabilize while the well is purged. Monitoring wells are occasionally sampled with bailers when there is a limited water column, and the well is particularly slow to recharge. The site groundwater sampling protocol includes detailed SOPs for all low-flow sampling methods deployed at the mine and is included as an appendix to the annual groundwater monitoring report included with each *MA/EMA* Annual Report submission.

Groundwater quality QA/QC comprises collection and analysis of field blanks, equipment blanks, and field duplicates with each sampling campaign. Travel blanks are also analyzed. Groundwater samples are analyzed for physical parameters, anions and nutrients, and total and dissolved metals in accordance with permit requirements. The annual groundwater monitoring report includes a discussion of QA/QC results.

Inflows to the underground mine (and pumped to the water treatment plant) are also recorded daily per the Water Management Plan – OMS Manual (Appendix 9-1-18). Underground dewatering rates attributed to groundwater inflows are computed using the daily data record and are discussed in the annual groundwater monitoring report.

Table 7.2-1. Summary information PE-107385 groundwater monitoring sites

Notes:
1. GWL = groundwater level; GWQ = groundwater quality; C = continuously recorded (logger); sQ = shifted quarter, B = biannual, NR = not required
2. Monitoring well top of pipe coordinates determined by RTK GPS, horizontal datum UTM Zone 9N NAD 83, Project vertical datum.
3. Coordinates of BJ-GW14-14B are from a handheld GPS in UTM NAD 83 Zone 9N. Vertical datum is unknown.

7.2.3 Surface Water Quantity and Water Management Infrastructure

The Brucejack Mine hydrometric monitoring program is designed to collect and analyze hydrometric data required under the monitoring provisions of PE-107835 and the MDMER of the federal *Fisheries Act*. As described in Section 2.6.1 and Section 2.4 of Appendix 5-2, the active hydrometric monitoring program consists of three streamflow monitoring stations and a level monitoring station (Figures 2.6-2 and 2.6-3; Table 2.6-1): hydrometric gauges at water monitoring sites BJ 3.10 and BJ 1.74, located along Brucejack Creek; a hydrometric gauge at SC-1 located along Sulphurets Creek; and the BJ WRTSF level monitoring station. Record periods for the three hydrometric stations are as follows: BJ 1.74 (2008 – present), BJ 3.10 (2014 – present), and SC-1 (2016 – present). The BJ WRTSF monitoring site is located upstream of the final effluent discharge location, monitoring site BJ 3.10. Water monitoring site BJ 1.74 is located along Brucejack Creek 1.36 km downstream of site BJ 3.10. The most-downstream node considered in the site-wide WBM coincides with the location of the BJ 1.74 monitoring station. Water monitoring site SC-1 is also an aquatic receiver monitoring location, situated on Sulphurets Creek downstream of Sulphurets Lake (Brucejack Creek drains to Sulphurets Creek).

Hydrometric monitoring standards adopted by Pretium are based on standards published by ENV (2018), the United States Geological Survey (Turnipseed and Sauer 2010), and the International Organization for Standardization (ISO 2007). Standard discharge measurement techniques (ENV 2018) are employed at stations BJ 3.10, BJ 1.74, and SC-1 (*e.g.*, 20-panel waded measurements with a current meter) whereas methods used in the development of stage-discharge rating curves follow as close as possible guidelines by ENV (2018) and ISO (2010). A stage-discharge rating curve is an empirical relation used to calculate streamflow (discharge) from continuously recorded water level data.

Rating curves for Brucejack monitoring stations are constructed using the Rating Development Toolbox within Aquarius Time-Series (AQTS). In concept, discharges and water levels are manually measured over a range of flow conditions (*i.e.*, low to high) to generate the curve. Typically, a minimum of ten discharge measurements across a range of stage and streamflow conditions are recommended to develop a robust stage discharge relationship (ENV 2018), a threshold that is well exceeded for the Brucejack hydrometric stations. Rating curves for monitoring stations are updated annually as new data becomes available and/or stream channel conditions change.

Continuous flow monitoring instrumentation, specifically magnetic flow meters, is also installed in-pipe to measure flow rates for the mine water influent at the WTP, CWP influent at the WTP, and WTP effluent. Continuous flow monitoring (flow meter) and continuous density monitoring (nuclear density gauge) is also in place for the tailings discharge lines going to the WRTSF which is used to determine the continuous flow of tailings supernatant. Cumulative flow per day is monitored for treated domestic effluent. There has never been direct discharge from the CWP to the WRTSF, however instrumentation is in place to measure daily volume of any diverted mine water, direct discharge volume and staff gauge levels if direct discharge is necessary.

The Water Management Plan - OMS Manual (Appendix 9-1-18) prescribes operations and monitoring of primary mine site surface water management infrastructure through the operations and closure phases at Brucejack. This infrastructure includes:

- CWP and spillway;

- Contact water management system of ditches, sumps, pumps, weirs and pipelines;
- Non-contact diversion channels; and
- LLW and reclaim system at the outflow of Brucejack Lake.

Surveillance of the water management facilities is conducted to determine if the facilities are operating within expected parameters. Deviations from expected performance may require adjustments to operation, maintenance or design to facilitate ongoing safe and efficient operation of the facilities. Surveillance is undertaken by two primary methods – visual inspection and reading of instruments. Results of these qualitative and quantitative observations are compared to the expected performance of the facilities. If observations are within the expected range or performance, the results of the surveillance are simply recorded. If observations are outside the expected range, the results of the surveillance are recorded, and further evaluation is completed to determine if remedial action is necessary. If remedial action is needed it may range from a minor adjustment to operational procedures to initiation of emergency response, depending on the severity and nature of the deviation from expected performance.

Routine visual surveillance includes:

- Visual inspections of mill-associated water management structures, CWP (crest, cut slopes, and spillway), all pumping system and pipelines from CWP to WTP and the direct WRTSF discharge system conducted once per shift by Mill Operators;
    - Staff Environmental Scientists accompany these inspections at least twice annually;
- Visual inspections of non-contact water diversion channels and all aspects of the contact water management system upstream of the CWP conducted by Waste Management and De-Watering Coordinators once per shift during non-frozen conditions;
    - Environmental Scientists accompany these inspections at least twice annually;
- Visual inspections of CWP crest, cut slopes, and spillway conducted by Environmental Scientists pre- and post-freshet and pre-freeze in the fall;
- Visual inspections of CWP and LLW each time water quality samples are collected by Environmental Scientists; and
- Annual inspection of CWP, all contact water management infrastructure and non-contact water diversion channels conducted by CWP/Water Management Consultant (Technical Lead or Senior Engineer). This inspection is to address the requirement for M-243 Condition C4(e) for a Professional Engineer to perform an annual inspection of water management facilities on site including surface water ponds, ditches and diversion channels.

Additional monitoring of the CWP is required to check for any seepage that could warrant geotechnical assessment since the CWP was constructed without a liner, as it has been excavated entirely within bedrock. This includes:

- Quarterly monitoring of groundwater levels (including datalogger downloads of water level) and groundwater quality in BJ-GW16-5A/B, installed northwest of the CWP, and BJ-GW18-23A/B, installed northeast of the CWP, following the methodologies and parameters of the permitted (PE-107835 and M-243) groundwater monitoring network; and
- Recording water volumes in the CWP on at least a daily frequency.

7.2.4 Surface Water Quality

The Brucejack Mine surface water quality monitoring program is designed to generate data that enable determination of discharge quality compliance and evaluation of mine-related effects on the aquatic receiving environment. Surface water quality is monitored at the Brucejack Mine as required by Condition 4 and Appendix A of PE-107835 (Appendix 1-1), and in accordance with applicable Brucejack Mine management plans, including the Aquatic Effects Monitoring Plan (Appendix 9-1-4), ML/ARD Management Plan (Appendix 9-1-11), Chromium Management Plan (Appendix 9-2-1), and Nitrogen Management Plan (Appendix 9-2-6). Mine surface water quality monitoring is also a requirement of Condition D.4(d) of *Mines Act* Permit M-234.

Surface water quality is monitored at the mine site locations shown in Figure 7.2-1 upstream of and including the mine final discharge location site BJ 3.10, at the frequencies listed in Table 7.2-2. Locations include WTP influent and all effluent discharges to the WRTSF as described in Section 7.1. Samples are analyzed for general parameters, major ions and nutrients, total and dissolved metals, and total organic carbon (refer to Table 7.2-2 notes and footnotes for additional details).

Figure 7.2-1. Mine site locations for surface water quality monitoring.

Table 7.2-2. Brucejack Mine Site and Discharge Water Monitoring Program

Station ID (EMS#) (lat., long.)	Description	Field Turbidity pH	Metals[1] & General[2]	Flow Rate / Staff Gauge	Toxicity
BJ 3.10 (E298312) (56.4696, 130.1878)	WRTSF outlet	-	Weekly	Continuous flow rate monitoring with manual checks quarterly	Quarterly
Mine Water Influent at WTP (E303052)	In plant prior to treatment	Continuous Monitoring	Two Times per Month	Continuous Monitoring	-
CWP Influent at WTP (E303053)	In plant prior to treatment	Continuous Monitoring	Two Times per Month (when discharging to the WTP)	Continuous Monitoring	-
WTP Effluent (E302957)	After treatment prior to WRTSF discharge	Continuous Monitoring	Two Times per Month	Continuous Monitoring	-
Tailings Supernatant (E302910)	After thickening prior to outfall	-	Monthly	Daily (cumulative flow per day)	-
Treated Domestic Effluent (E302911)	After treatment prior to outfall	-	Quarterly (BOD and TSS only)	Daily (cumulative flow per day)	-
CWP Direct Discharge to WRTSF (E306114)	In CWP or direct discharge line	Two Times per Day	Once for each direct discharge event	-Daily volume of any diverted mine water -Direct discharge volume and 2 times daily staff gauge levels -May through October (sQ 2&3) 2 times weekly staff gauge levels	-

[1] Metals refers to Low level ICP or equivalent analysis of Total and Dissolved Metals including Aluminum, Antimony, Arsenic, Barium, Beryllium, Bismuth, Cadmium, Chromium, Cobalt, Copper, Iron, lead, Lithium, Manganese, Molybdenum, Nickel, Selenium, Silver, Strontium, Thallium, Tin, Uranium, Vanadium and Zinc, and Mercury analysis which are to be included at the WRTSF outlet (BJ 3.10), the WTP effluent, the tailings supernatant on a s Quarterly basis.

[2] General Parameters are defined as:

- Laboratory analysis: pH, Specific Conductivity, Hardness, Alkalinity, Sulphate, Chloride, Fluoride, Calcium, Magnesium, Sodium, Ammonia, Nitrate, Nitrite, Total & Ortho Phosphorous, Total Organic Carbon, Total Suspended & Total Dissolved Solids, and Turbidity;
- Field measurements: Turbidity, pH, Conductivity and Temperature;
- Dissolved Phosphorous and Dissolved Organic Carbon which are to be included as part of the General Parameters at Site BJ 3.10 at a frequency of 3x/ ice free period, and 1x mid-winter; and
- Total Extractable Hydrocarbon analysis which is to be included at the CWP prior to direct discharge to Brucejack Lake and prior to treatment at the WTP; at a frequency of once for each event that DPS pond effluent is pumped to the CWP.

Aquatic receiving environment surface water quality monitoring locations in Brucejack Creek are shown in Figure 7.2-2 and Figure 7.2-3 shows monitoring location in upper Sulphurets Creek. Monitoring frequencies are listed in Table 7.2-3. Aquatic receiving environment monitoring locations are BJ 2.62, BJ 1.74, and SC0; the reference monitoring location is site L3-OF. Samples are analyzed for general parameters, major ions and nutrients, total and dissolved metals, and total organic carbon (refer to Table 7.2-3 notes and footnotes for additional details).

Figure 7.2-2. Aquatic receiving environment surface water quality monitoring locations (BJ 2.62 and BJ 1.74).

Figure 7.2-3. Aquatic receiving environment surface water quality monitoring locations (SC0).

Table 7.2-3. Brucejack Mine Surface Environmental Water Monitoring Program

Station ID (EMS#) (lat., long.)	Description	Metals[1] & General[2]	Flow Rate	5 in 30 days[3]
BJ 2.62 (E298332) (56.4697, 130.1978)	Brucejack Creek upstream of VOK Ck & downstream of Camp Creek	Monthly	-	-
BJ 1.74 (E298333) (56.4699, 130.2048)	Brucejack Creek downstream of VOK Creek	Monthly (May through October (sQ 2&3)) Quarterly (sQ 1&4)	Four times per summer (manually at low flow and no recent precipitation)	-
CC 0.87 (E298331) (56.4636, 130.1852)	Camp Creek 0.87 km upstream of confluence with Brucejack Creek	Monthly	-	-
CC 0.01 (E298334) (56.4686, 130.1914)	Mouth of Camp Creek	Monthly	-	-
SC0 (E303050) (56.4929, 130.2662)	Sulphurets Creek approximately 6.5 km downstream of the WRTSF	sQuarterly[4]	-	Once every 3 years
L3 OF (E303051) (56.5703, 130.2662)	Reference creek ~20 km north-west of mine site; outflow of L3 Lake	sQuarterly[4]	-	Once every 3 years

[1] Metals refers to Low level ICP or equivalent analysis of Total and Dissolved Metals including: Aluminum, Antimony, Arsenic, Barium, Beryllium, Bismuth, Cadmium, Chromium, Cobalt, Copper, Iron, lead, Lithium, Manganese, Molybdenum, Nickel, Selenium, Silver, Strontium, Thallium, Tin, Uranium, Vanadium and Zinc; and Mercury analysis which are to be included at Site BJ 2.62, SCO, BJ 1.74, on a sQuarterly basis. The mercury sampling frequency at Site L3 outflow must be during freshet and fall.

[2] General Parameters are defined as:

- Laboratory analysis: pH, Specific Conductivity, Hardness, Alkalinity, Sulphate, Chloride, Fluoride, Calcium, Magnesium, Sodium, Ammonia, Nitrate, Nitrite, Total & Ortho Phosphorous, Total Organic Carbon, Total Suspended & Total Dissolved Solids, and Turbidity;
- Field measurements: Turbidity, pH, Conductivity and Temperature; and
- Dissolved Phosphorous and Dissolved Organic Carbon which are to be included as part of the General Parameters at Site BJ 2.62 at a frequency of 3x/ ice free period, and 1x mid-winter.

[3] 5 in 30 days refers to 5 samples collected within 30 days, required at freshet and fall.

[4] sQuarterly refers to the following quarters: sQtr 1 (February, March, & April), sQtr 2 (May, June & July), sQtr 3 (August, September & October), and sQtr 4 (November, December & January).

WTP effluent quality is compared to discharge limits specified in PE-107835 and to long-term trends to ensure that treatment efficiency is maintained. BJ 3.10 monitoring results are compared to discharge limits specified in PE-107835 and to BC WQG for the protection of FWAL for parameters without discharge limits and reported according to Condition 5 of PE-107855.BJ 3.10 and BJ 2.62 monitoring results are evaluated in the *MA/EMA* Annual Reports in comparison to modelled water quality to determine if observed water quality is in-line with expected water quality. Where differences are observed, discussion of potential mine-related effects to surface water quality is presented. Monitoring of the various inputs to the WRTSF (Table 7.2-2) aid in the assessment of potential causes of differences between measures and modelled water quality, and in the development of remedial actions, if necessary. Monitoring results from reference station L3-OF and tributaries to Brucejack Creek, such as Camp Creek, aid in distinguishing changes to water quality in Brucejack Creek that are mine-related from natural changes.

7.2.5 Geochemical Source Terms and Solid Mine Wastes

The Brucejack Mine maintains a comprehensive monitoring program to verify geochemical source terms related to solid waste generated during mine production and development (Table 7.2-4). These source terms are incorporated into the mine's water quality model (Appendix 5-3) and are reviewed annually and updated as required. The geochemical and solid mine waste monitoring program includes:

- Material generated on surface within the mine site area, such as the NPAG quarry rock currently used for surface and underground construction material
- Lithology specific characterization of underground mine waste rock intended for deposition in the WRTSF or backfill within the mine, below the closure flooding elevation
- Characterization of thickened tailings and paste backfill cement, prior to deposition in the WRTSF or underground placement
- Water treatment plant sludge prior to co-mingled deposition with tailings into the WRTSF

Source terms are further developed from water quality samples associated with solid mine waste runoff and leachate, including:

- Mine site surface contact water reporting to the CWP and runoff from the NPAG quarry
- Leachate from saturated column, humidity cell, and field bin kinetic testwork for mine site surface (including the NPAG quarry) and underground waste rock
- Leachate from saturated column and humidity cell testwork for paste backfill and thickened tailings co-mingled with WTP sludge
- Thickened tailings supernatant and paste backfill bleed water
- Underground sumps reporting to the WTP and groundwater seeps reporting to the underground mine pool

Further description of the mine's geochemical source terms and solid mine waste monitoring programs are found in the ML/ARD Management Plan (Appendix 9-1-11), Chromium Management Plan (Appendix 9-2-1), and Nitrogen Management Plan (Appendix 9-2-6). Source term development is described in the Brucejack Mine: 4950 tpd Water Quality Model Report (Appendix 5-3).

Table 7.2-4. Brucejack Mine Geochemical and Solid Mine-waste Monitoring Program.

Station ID / Sample Type (EMS#	Description	Static Testwork[1] (Frequency)	Kinetic Testwork (Frequency)	Water Quality[2] (Frequency)	Flow Rate
MINE SITE					
NPAG Quarry (-)	Drill cuttings collected prior to blasting; quarry runoff water quality, and field bin water quality	ABA, Metals, SFE (per 10,000 m^3)	Field bin leachate (seasonal – summer)	Quarry runoff (bi-annual – spring and fall)	Manually collected at time of sampling
Surface Waste Rock (-)	Surface waste rock excavated during construction, prior to subaqueous deposition in the WRTSF and contact water diversions	ABA, Metals, SFE (per 10,000 m^3)	Saturated column leachate; Field bins (seasonal – summer)	Contact water (bi-annual – spring and fall)	Manually collected at time of sampling
PROCESS PLANT					
Thickened Tailings Slurry (E302910)	Thickened tailings prior to subaqueous deposition via pipeline to the WRTSF	ABA, Metals, SFE (Monthly)	Saturated column leachate (monthly); humidity cell leachate (Monthly)	Thickened tailings supernatant (Monthly)	Daily[3]
Water Treatment Plant Sludge (E302910)	WTP sludge prior to co-mingled subaqueous deposition with thickened tailings to the WRTSF	ABA, Metals (Quarterly); SE (Annually)	Saturated column leachate (Monthly)	-	Daily[3]
Paste Backfill (-)	Paste backfill prior to placement underground and, pate backfill bleed water following placement	ABA, Metals, SFE (Monthly)	Saturated column leachate (monthly), humidity cell leachate (Monthly)	Six chromium samples collected from 2 stopes (Annually)	-
Cement Binder (-)	Cement binder (Terraflow) prior to mixing with thickened tailings to form paste backfill	Chromium[5] (Monthly)	-	-	-
UNDERGROUND MINE					
Underground Waste Rock (-)	Lithology specific waste rock samples collected during mine development	ABA, Metals, SFE (per 25,000 m^3)	Wall washing (annual – water quality, surface oxidation products, and waste rock); saturated column leachate (monthly); humidity cell leachate (monthly); field bin leachate (seasonal – summer)	-	-
Underground Mine Water	Water reporting to underground sumps, or from mine seeps	-	-	Sumps and seeps (sQuarterly)	Manually collected at time of sampling (Seeps only)

1. ABA: acid-base accounting; Metals: solid phase elemental abundance by ICP-MS; SFE: shake flask extraction; SE: sequential extraction.
2. Water quality analysis suite includes general parameters, nutrients, total and dissolved metal (including mercury); dissolved organic carbon is analyzed in UG sumps.
3. Cumulative daily flow.
4. As per the ML/ARD Management Plan.
5. As per the Chromium Management Plan.

7.2.6 Toxicity Testing

Toxicity testing of effluent is conducted quarterly on water collected at BJ 3.10 following the procedures described in the British Columbia Field Sampling Manual Part E: Water and Wastewater Sampling (ENV 2013), as per Section 4.3 and 4.4 of the *EMA* permit (PE-107835) (Appendix 1-1). Testing is completed for a single concentration of 100% effluent, with effluent grab samples collected and processed without delay at an accredited facility. Test reports are included in Section 5.4 of the *MA/EMA* Annual Reports.

Quarterly toxicity tests required by Condition 4.3 of PE-107835 are:

- 48-hour acute lethality assay Daphnia magna (EPS 1/RM/14 2nd edition; EC 2000a); and
- 72-hour growth inhibition test using Pseudokirchneriella subcapitata (freshwater algae) (EPS 1/RM/25; EC 2007a).

Quarterly long-term trend toxicity testing required by Condition 4.4 of PE-107835 is:

- Survival and growth of the freshwater midge Chironomus dilutus (EPS 1/RM/32; EC 1997).

Results of the long-term toxicity testing are examined for trends in survival and growth, compared to previous tests, and placed into ecological context.

PE-108735 Condition 4.3 specifies that *Daphnia magna* tests must have a minimum survival of 50% in undiluted effluent, and that the algal growth inhibition test must have less than 25% growth inhibition in undiluted effluent compared to laboratory control water. Failure of either the *D. magna* survival or the algal growth test require an immediate non-compliance notification. PE-107835 Condition 4.4 specifies that, beginning in 2019, 100% effluent collected at BJ 3.10 be tested for survival and growth using larvae of freshwater midges (*Chironomus dilutus*) and trends in survival and growth be described in *MA/EMA* Annual Reports. The *Chironumus* tests are for examining long-term trends, and results are not used for compliance reporting.

QA/QC procedures for sample collection follow those outlined in the British Columbia Field Sampling Manual Part A: Quality Control and Quality Assurance (ENV 2013). Samples are collected by qualified personnel using suitable sampling equipment and are stored and transported using accepted procedures. Chain-of-Custody forms are used.

All laboratory processing and assays are conducted by accredited facilities.

Additional toxicity testing is required by MDMER. Section 2.7.1.1describes historical toxicity testing, while the information presented below describes present toxicity monitoring. Similar to the samples collected as required by PE-107835, the procedures described in the British Columbia Field Sampling Manual Part E: Water and Wastewater Sampling (ENV 2013) are followed and testing is completed for a single concentration of 100% effluent, with effluent grab samples collected and processed without delay at an accredited facility. All test reports are submitted on the Mine Effluent Reporting System (MERS) via the Single Window Information Manager (SWIM).

Quarterly toxicity testing required by MDMER includes:

- Single-concentration test to determine the mortality rate or Daphnia magna at 48 hours (Reference Method EPS 1/RM/14 2nd edition; EC 2000a); and
- Single-concentration test to determine the mortality rate of Rainbow trout at 96 hours (Report EPS 1/RM/13; EC 2000b).

Quarterly long-term trend toxicity testing required by PE-107835 includes:

- Test of reproduction and survival using the Cladoceran Ceriodaphnia dubia (Report EPS 1/RM/21; EC 2007b).

7.3 Aquatic Receiving Environment / Aquatic Effects Monitoring Program

The existing aquatic effects monitoring program, including monitoring of the aquatic receiving environment that receives Brucejack Mine effluent, is outlined in Effluent Permit 107835 and described in the AEMP (Appendix 9-1-4). The AEMP is designed to generate data needed to accomplish the following objectives:

1. <u>Determine the short- and long-term effects in the aquatic environment resulting from the mine:</u>

   Met by monitoring the aquatic receiving environment via AEMP and PE-107835 monitoring implementation in the short term (on an annual basis) and the long term (across all phases of mine life), augmented by more frequent effluent and receiving environment water quality monitoring. Physical, chemical, and biological characteristics of the aquatic environment are monitored to provide data needed to detect mine effects on the receiving environment.

2. <u>Evaluate the accuracy of mine effect predictions:</u>

   Evaluated based on the results of the monitoring plan addressed in Objective 1, and as part of the regular reporting process.

3. <u>Assess the effectiveness of existing mitigation and management measures:</u>

   The effectiveness of mitigation measures is determined by identifying changes in the receiving environment, which triggers assessment of the significance of such changes and – if significant – follow-up as appropriate (Objective 4). Results of AEMP monitoring and analyses are reported in the *MA/EMA* Annual Reports.

<u>Identify the need for additional mitigation measures to avert or reduce adverse environmental effects due to mine activities (adaptive management):</u>

The AEMP prescribes that if unanticipated effects or poor performance of existing measures are identified, additional mitigation and management measures will be developed. These additional proposed mitigation and management strategies are to be described in the *MA/EMA* Annual Reports.

4. <u>Comply with permit and other regulatory requirements:</u>

   Section 4.5 of PE-107835 requires that the AEMP and any proposed changes to it be approved by the director, and stipulates monitoring results submission requirements, including that these be prepared by a Qualified Professional. Environmental components specified in the AEMP are evaluated for effects by the methods outlined in the AEMP. These methods conform to ENV guidance documents (BC MOE 2016; EC 2012a; ENV 2013). Monitoring follows the

requirements specified in PE-107835 Section 4. PE107835 Section 5.5 requires that the AEMP annual report include results and interpretation of toxicity testing (acute and chronic), sediment and biological monitoring, key water quality trends, environmental effects, and an assessment of the protectiveness of the discharge limits. The MDMER study design and results are reported separately from the AEMP.

The AEMP study area comprises those aquatic receiving areas potentially influenced by Brucejack Mine activities (exposure), and areas beyond potential mine influences (reference). The primary mine-related activities that could affect the aquatic receiving environment, and that were therefore considered in the AEMP design, include:

- discharge of water from the WRTSF, which is the location of subaqueous deposition of waste rock and tailings and which receives treated effluent from the mine WTP and STP. The WRTSF outflow (monitoring site BJ 3.10) is the mine's discharge point into the Brucejack Creek aquatic receiving environment, and is the point of compliance for the EMA permit and MDMER;
- runoff from mine infrastructure, including pads, stockpiles, and roads. Most runoff from mine infrastructure is either contained within the contact water collection area and directed to water treatment, or drains passively to the WRTSF as per the OMS Manual - Water Management Plan (Appendix 9-1-18); and
- changes in streamflow related to mine water management and discharges.

AEMP monitoring sites are situated to monitor the aquatic receiving environment along the downstream gradient from the WRTSF to the inflow to Sulphurets Lake (Table 7.3-1 and Figure 7.3-1).

The monitoring components, with their respective sampling frequency and replication, are provided in Table 7.3-2. Section 6.3 of the AEMP (provided as Appendix 9-1-4) describes these monitoring components in greater detail.

Refer to the AEMP for additional details (Appendix 9-1-4).

The sampling design for the AEMP is conceived to provide information for a statistical analysis incorporating a Before-After/Control-Impact (BACI) design on aquatic receiving environment indicators. Baseline information for the sampling locations (Table 7.3-1) is available from 1987 to 2014 (see Sections 13.3 and 14.3 in Chapters 13 and 14 of the Application for an Environmental Assessment Certificate /Environmental Impact Statement, ERM Rescan 2014a), and are the basis for the "Before" category in AEMP statistical analyses. Monitoring for the "After" category commenced in 2015, when the Construction Phase of the mine was initiated, with commercial production achieved on July 1, 2017.

Table 7.3-1. AEMP Monitoring Locations, Descriptions, and Purposes

Site	EMS ID	Location[a]		Description	Purpose
		Easting	Northing		
Mine Site Area					
BJ 3.10 (Weir)	E298312	426,820	6,258,983	WRTSF outflow	Mine discharge location; final discharge point for MDMER and effluent compliance conditions for PE-107835
CC 0.87[b]	E298331	426,951	6,258,242	Headwaters of Camp Creek	Upstream control site
CC 0.01[b]	E298334	426,601	6,258,868	Mouth of Camp Creek	Site to estimate non-contact water contributions from Camp Creek to Brucejack Creek.
BJ 2.62[b]	E298332	426,330	6,258,959	Brucejack Creek, immediately downstream of cascades	Monitor the receiving environment on Brucejack Creek approximately 0.5 km downstream of WRTSF outflow and downstream of Camp Creek.
BJ 1.74[b]	E298333	425,773	6,259,026	Brucejack Creek, downstream of VOK Creek confluence	Monitor the receiving environment on Brucejack Creek approximately 1.4 km downstream of WRTSF outflow
SC0[b]	E303050	422,038	6,261,659	Sulphurets Creek, downstream of Sulphurets Glacier, inflow to Sulphurets Lake	Far-field exposure site.
Access Road					
KG 0.4	-	439,360	6,251,460	Creek flowing from Knipple Glacier, upstream of bridge	Hydrocarbon monitoring location; not included in EMA permit
Reference Areas					
L3 Outflow[b]	E303051	413,622	6,270,435	Reference stream; lake-headed high alpine reference stream comparable to Brucejack Creek, located 17 km northwest of Brucejack Lake	Brucejack Creek reference stream site
T2 0.09	-	427,106	6,259,483	Catear Creek; northern tributary to Brucejack Lake	Applicable to MDMER sampling only. Upstream reference site for Brucejack Creek; downstream of historical Catear Mine site; Environment and Climate Change Canada recommended MDMER biological reference site

[a] UTM Zone 9, NAD83
[b] Sampling schedule may be adjusted during the winter months depending on conditions (i.e., flying, creek frozen to ground) and avalanche hazard.

The monitoring components, with their respective sampling frequency and replication are provided in Table 7.3-2. Section 6.3 of the AEMP (provided in Appendix 9-1-4) describe these monitoring components in greater detail.
Refer to the AEMP for additional details (Appendix 9-1-4).

7.4 Post-Closure Environmental Monitoring Program

Monitoring is required under Section 10.7.21 of the Code to demonstrate that reclamation and environmental protection objectives including land use, productivity, water quality, and stability of structures are being achieved. Mine closure is estimated to be completed within three years, followed by post-closure monitoring over the following ten years. The results of the monitoring program are to be included in the Annual Reclamation Report (per Section 10.4.4 of the Code).

The following summarizes conceptual post-closure monitoring planned for the Brucejack Mine. The length of time required for monitoring may be extended if the early results of the program indicate further monitoring is required. All facilities will be dismantled and/or removed from site during closure with site drainage and landforms contoured to a final closed state. As such, regular maintenance is not anticipated. Maintenance needs will be identified on an as-needed basis based on the monitoring and inspection programs described below.

Monitoring programs are anticipated to evolve and decrease in scope through the closure and post-closure periods. During the closure period, monitoring programs will focus on monitoring and management of reclamation activities, confirming of ongoing compliance with regulatory requirements, and including confirming effectiveness of water quality protection related closure activities relative to modelled predictions such that adaptive management will be triggered if/as appropriate (e.g. Closure Underground Water Quality Adaptive Management Plan, Appendix 9-2-2).

During the post-closure period, monitoring programs will focus on demonstrating reclamation success. The general scope of post-closure monitoring programs includes:

- Surface water quality, sediments, and aquatic biological resources;
- Groundwater quality and levels, including water chemistry and level in the underground mine as feasible;
- Structural integrity of portals and raise watertight plugs;
- Geotechnical assessment of post-mine landform and watercourse stability, including for the surface above the underground mine (subsidence); and
- Assessments of reclamation program success in meeting the end land use objectives.

Additional details are provided in section 12 of the Reclamation and Closure Plan (Appendix 4-1).

8. HEALTH AND SAFETY

Existing Brucejack Mine Health and Safety related management plans and associated procedures will remain in effect with the proposed production rate increase; no changes are necessary specific to the change in production rate. The Mine Emergency Response Plan is included as Appendix 9-1-12, and the Health Services Monitoring Program is Appendix 9-1-9. A summary of Brucejack Mine emergency preparedness is provided as follows.

Due to its remote location, the Brucejack Mine has a medical clinic staffed with a Registered Nurse (RN), Advanced Care Paramedic (ACP), or Primary Care Paramedic (PCP) combination to provide site healthcare, and with the ability to enable offsite medical transfer via land or air for any conditions requiring higher level of care.

The mine's emergency response procedures incorporate on-site mine rescue teams composed of an interdepartmental workforce trained in first aid, fire-fighting procedures, and other mine rescue operations. Emergency coordination occurs from the incident control room, where all information and communications can be monitored. A variety of incidents will initiate the emergency response plan and/or evacuation plan including fire, rock fall, injured personnel, or major ventilation equipment breakdown.

The underground mine ventilation system is designed to meet the Code requirements (EMLI 2022). The 'push' configuration of the mine ventilation system distributes fresh air to the mine via the WZ and VOK ramps. Both ramps serve as escapeways for most levels.

Ladderways are installed in each of the fresh air intake raises located adjacent to the main ramps and serve as the primary escape ways for the production stoping blocks. The fresh air intake raises are appropriately sized to afford easy passageway and are designed, installed, and maintained in compliance with Code sections 6.28.1 through 6.28.7 (EMLI 2022). The exhaust raises to surface are for ventilation only and do not provide secondary egress; therefore, the exhaust raises do not have ladderways.

A stench gas warning system is installed on the supply side of the WZ vehicle portal and VOK conveyor portal. When initiated, this system will release stench gas into the main fresh air system, allowing the gas to permeate rapidly throughout the mine workings. Once stench gas is released, underground mine personnel report immediately to the nearest mine refuge station or to surface, depending on proximity and safe access.

A permanent 40-person refuge station has been established and services both the WZ and VOK, and a permanent 60-person refuge station has been established and services the lower VOK. Additional portable refuge chambers are positioned within the most appropriate areas for ongoing mining activity. A summary of the refuge stations is provided in Table 8-1.

Fire doors are positioned in accordance with Code sections 6.32.1 and 6.32.2 (EMLI 2022) and are intended to isolate areas of high fire potential and prevent noxious gas distribution through the mine workings. The primary purposes of fire doors are to prevent noxious gases from reaching workers should they be trapped underground and to prevent fire from spreading as much as possible. Fire doors have also been installed to isolate the magazine and conveyor decline. The mine portal doors are designed to meet fire door criteria.

Table 8-1. Summary of Refuge Stations

Refuge #	Location	Capacity
1	1440 Escapeway	12
2	1020 Escapeway	16
3	1260-15	16
4	1110 East RM	16
5	1170 Escapeway	16
6	1335 Permanent	40
7	1080 Escapeway	16
8	1200-16 Permanent	60
9	WZ 1270 Ramp	6

9. MANAGEMENT PLANS

9.1 Environmental Management System

The Brucejack Mine EMS is comprised of 21 component management plans required under Schedule B of EAC #M15-01 and 10 additional management plans required through other BC provincial authorizations (mainly Permit M-243, PE-107835 and PA-107025). The 21 EAC component management plans are provided in Appendix 9-1, except for the Reclamation and Closure Plan which is provided in Appendix 4-1. The 10 additional management plans are provided in Appendix 9-2. A list of the management plans and their associated review and distribution histories is provided in Table 9.1-1. The Reclamation and Closure Plan has been updated to reflect mine site changes since the last major update in 2020.

It should be noted that there are several differences in management plan terminology between the requirements under EAC #M15-01 and the M-243 and other authorizations requiring plans:

- EAC #M15-01 refers to the entire compilation of required management plans as the 'Environmental Management Plan' (EMP) whereas Mines Act Permit M-243 uses the more typical terminology of an EMS with component EMPs.
- EAC #M15-01, Schedule B, Appendix A lists a 'Tailings and Subaqueous Waste Rock Deposition Management Plan'. This management plan has been expanded to an OMS Manual to meet EMLI requirements under M-243 Condition C.3(a)(i) for content that includes procedures, reporting and responsibility information. The title of this document as included in Appendix 9-1-17 is OMS Manual – Waste Rock and Tailings Storage Facility.
- EAC #M15-01, Schedule B, Appendix A lists a 'Water Management Plan'. This management plan has also been expanded to an OMS Manual to meet EMLI requirements under Permit M-243.

9.1.1 Environmental Policy Statement

Pretium adheres to the Newcrest Mining Ltd. Environmental Policy which states that Newcrest is committed to excellence in environmental performance to maintain and enhance our license to operate and commits to the following:

- Inform all employees, contractors and vendors about this Policy and make them aware of their environmental responsibilities;
- Throughout the life-cycle of our activities engage with stakeholders to identify and manage sustainable development risks and opportunities as part of our business planning and execution;
- Comply with applicable environmental laws, regulations and voluntary commitments to which the organisation subscribes, as a minimum;
- Ensure effective systems, practices and documented plans are in place to manage and mitigate environmental impacts and pollution from our activities by proactively managing risks;

- Establish and document processes to identify and manage risks and opportunities for the efficient use of energy and water, manage emissions linked with climate change and reduce waste generation that lessens the Company's environmental footprint;
- Ensure that integrated approaches to land use planning and environmental management are implemented in areas where we operate and/or manage that contribute to the conservation of biodiversity;
- Integrate mine closure and progressive rehabilitation into the life-cycle of our operations to minimise our environmental legacies;
- Continually strive to improve our environmental performance based on defined objectives and targets for monitoring, measuring and reporting performance; and
- Report openly, honestly and in a timely manner to stakeholders on the Company's environmental and sustainability performance.

9.1.2 Environmental Management Plans Content

Each of the management plans contains information as relevant on the following:

- Roles and responsibilities;
- Information on statutory requirements, including applicable local, provincial, or federal environmental standards and guidelines, permit requirements, regulations, and orders;
- Information on environmental standards and procedures, including all applicable sector-specific standards, guidelines, best management practices, and codes of practice;
- Organizational structure; and
- Training programs.

9.1.3 Training Program

In addition to the specified training within each of the EMPs, all site personnel complete an environmental site orientation prior to commencing work on site. The goal of the environmental site orientation is to educate and train all employees and contractors on the EMS and specifically on relevant EMPs.

Table 9.1-1. Summary of EAC Component Management Plans and Plans per Other Provincial Authorizations and Requirements

Brucejack Mine Management Plans	Relevant Regulatory Authority	Current Version Date (Revision Status)	Distribution Timing/Status	Reviews/Audits
BC EAC #M15-01 Component Management Plans (refer to Appendix 3-1-1 for plans)				
Aboriginal Consultation Plan (Appendix 9-1-1)	EAO	January 2022	September 2016 edition sent to EAO, Nisga'a Lisims Government and First Nations September 16, 2016; submitted to EAO on December 31, 2018 and with *MA & EMA* joint 2018 Annual Report submitted March 2019; submitted with *MA & EMA* joint 2020 Annual Report in March 2021; current version submitted with *MA & EMA* joint 2021 Annual Report in March 2022; internally via Management Plans folder.	Version control table and cover page updated in 2018. No significant changes required based on 2019 review. In March 2021, the Plan was updated to reflect changes in contact info and reference made to Spill Response Plan. In January 2022, the Plan was updated to reflect changes to key contacts. No changes were made based on 2023 review.
Air Quality Management Plan (Appendix 9-1-2)	ENV	January 2022	Original May 2015 via *MA & EMA* Permits Application; submitted to EAO on December 31, 2018 and with *MA & EMA* joint 2018 Annual Report submitted March 2019; submitted with *MA & EMA* joint 2020 Annual Report in March 2021; current version submitted with *MA & EMA* joint 2021 Annual Report in March 2022; internally via Management Plans folder.	Annual major plan audit via Annual Air Quality Report and related compliance assessment (Annual Status Form) submitted to ENV (and EMLI) as part of the Annual Report due by March 31st of the following year. The plan was sent out for review/consultation in 2019 with relevant Indigenous groups, and comments were received. The review process continued through 2020 and an updated version, reflecting comments via consultation, was prepared in January 2021. In January 2022, the Plan was updated to include references to compliance limits in 2021 air permit amendment. No changes were made based on 2023 review.
Ancillary Infrastructure Decommissioning and Reclamation Plan (Appendix 9-1-3)	LWRS/Forests/EMLI	December 2018	Original May 2015 via *MA & EMA* Permits Application; current edition submitted to EAO on December 31, 2018 and with *MA & EMA* joint 2018 Annual Report submitted March 2019; internally via Management Plans folder.	Content was updated based on the 2018 review to reflect constructed infrastructure rather than proposed, and to separate ancillary infrastructure from that within the M-243 permitted area. No changes required based on 2019 review. No changes based on 2020 review. No changes based on 2021 review. No changes based on 2022 review.
Aquatic Effects Monitoring Plan (Appendix 9-1-4)	ENV	February 2022	Original May 2015 via *MA & EMA* Permits Application; submitted to EAO on December 31, 2018 and with *MA & EMA* joint 2018 Annual Report submitted March 2019; submitted with *MA & EMA* joint 2019 Annual Report in March 2020; submitted with *MA & EMA* joint 2020 Annual Report in March 2021; current version submitted with *MA & EMA* joint 2021 Annual Report in March 2022; internally via Management Plans folder.	Plan is reviewed a minimum of annually, including via the Annual Aquatics Report and related compliance assessment (Annual Status Form) required by ENV as part of the MA/EMA Annual Report. Based on the 2018 review, the Plan was updated to align with the amended effluent permit (PE-107835) issued Dec. 14th, 2018, and with MDMER revised regulations. In 2019, comments were received by ENV in consultation with Nisga'a Lisims Government, which were reflected in the February 2020 update. In March 2021, the plan was again updated to add zinc triggers to the monitoring program. In February 2022, the plan was updated to reflect changes to cited references. No changes were made based on 2023 review.
Avalanche Safety Plan (EAC Preliminary Avalanche Hazard Management Plan for Mine Construction and Operations) (Appendix 9-1-5)	LWRS/Forests/EMLI	October 2023 (updated)	Original May 2015 via *MA & EMA* Permits Application; *MA & EMA* joint 2017 Annual Report submitted March 2018; submitted to EAO on December 31, 2018 and with *MA & EMA* joint 2018 Annual Report submitted March 2019; submitted with *MA & EMA* joint 2020 Annual Report in March 2021; current version submitted with *MA & EMA* joint 2021 Annual Report in March 2022; internally via Management Plans folder.	Avalanche Safety Plan produced in 2018 replaces the original Preliminary Avalanche Hazard Management Plan from 2015. The Avalanche Safety Plan is used operationally by Pretium's Mountain Safety avalanche technicians and is reviewed and updated frequently (generally annually). There are frequent inspections/audits under the plan by Pretium's full-time year-round Mountain Safety avalanche technicians. No significant changes required based on 2019 review. Plan was reviewed in 2020 and updated February 2021 to reflect changes in operational procedures. Plan was once again reviewed in 2021 and updated in February 2022 to reflect changes to operational procedures. No changes were made based on 2023 review. Appendix N was added in October 2023.
Chemicals and Materials Storage and Handling Plan (Appendix 9-1-6)	MEMLI/ENV	January 2023 (updated)	Original May 2015 via *MA & EMA* Permits Application; *MA & EMA* joint 2016 Annual Report submitted March 2017; *MA & EMA* joint 2017 Annual Report submitted March 2018; submitted to EAO on December 31, 2018 and with *MA & EMA* joint 2018 Annual Report submitted March 2019; submitted with *MA & EMA* joint 2020 Annual Report in March 2021; current version submitted with *MA & EMA* joint 2021 Annual Report in March 2022; internally via Management Plans folder. Current edition submitted via 2022 Annual Report; internally via Management Plans folder.	Lessons learned from the execution of several mock spill chemical response drills at different times of the year (i.e., winter and summer) with different crews and locations, were incorporated into the Plan update in December 2018. The 2018 update also includes revisions for Operations chemicals and materials. No changes required based on 2019 review. A 2020 review resulted in updates to newly added (in 2020) reagents used in the milling process. In July 2021, the Plan was updated to reflect changes to the chemicals and materials used for mine operations and to the Mill Reagent Storage Plan. In November 2022 the Plan was updated to reflect changes to chemicals and materials used for mine operations and to the Mill Reagent Storage Plan. In January 2023 the Plan was updated to reflect changes to Table 6-1 (Chemicals and Materials for Mine Operation).

Brucejack Mine Management Plans	Relevant Regulatory Authority	Current Version Date (Revision Status)	Distribution Timing/Status	Reviews/Audits
Economic and Social Effects Mitigation Plan (Appendix 9-1-7)	EAO	March 2022	March 2017 edition sent to NLG, Tahltan Central Government (TCG), Tsetsaut/Skii km Lax Ha First Nation (TSKLH) and EAO March 30, 2017; current edition submitted to EAO on December 31, 2018 and with *MA* & *EMA* joint 2018 Annual Report submitted March 2019; internally via Management Plans folder. Current edition submitted via 2022 Annual Report; internally via Management Plans folder.	Based on the 2018 review the plan was updated to reflect activities completed to date. Annual report on implementation of the plan sent to NLG, TSKLH, TCG, EAO and local communities from Telegraph Creek to Smithers on January 31, 2019. No changes required based on 2019 review. No changes required based on 2020 or 2021 review. In March 2022, the Plan was updated and sent to NGL, TSKLH, TCG, EAO and local communities from Telegraph Creek to Smithers.
Heritage Management Plan (Appendix 9-1-8)	LWRS/Forests/EMLI	January 2023 (updated)	Original May 2015 via *MA* & *EMA* Permits Application; current edition submitted to EAO on December 31, 2018 and with *MA* & *EMA* joint 2018 Annual Report submitted March 2019; internally via Management Plans folder. Current edition submitted via 2022 Annual Report; internally via Management Plans folder.	Version control table and cover page updated in 2018. No changes required based on 2019 review. No changes required based on 2020 review. No changes based on 2021 review. Version control table and cover page updated January 2023.
Health Services Monitoring Plan (Appendix 9-1-9)	EAO	November 2023 (updated)	June 2016, distributed to Northern Health and Nisga'a Lisims Government and First Nations; current edition submitted to EAO on December 31, 2018 and with *MA* & *EMA* joint 2018 Annual Report submitted March 2019; internally via Management Plans folder. Current edition submitted via 2022 Annual Report; internally via Management Plans folder.	Plan was originally developed in consultation with Northern Health per EAC requirements. Northern Health conducts (minimum) annual physical inspections of the camp and related medical facilities, and there are monthly meetings between Pretium Health and Safety and Northern Health to review implementation. Version control table and cover page updated in 2018. No changes based on 2019 review. No changes based on 2020 review. No changes based on 2021 review. Version control table and cover page updated in January 2023. Significant updates to general infrastructure references and general updates throughout.
Invasive Plants Management Plan (Appendix 9-1-10)	LWRS/Forests/EMLI	January 2023 (updated)	Original May 2015 via *MA* & *EMA* Permits Application; current edition submitted to EAO on December 31, 2018 and with *MA* & *EMA* joint 2018 Annual Report submitted March 2019; internally via Management Plans folder. Current edition submitted via 2022 Annual Report; internally via Management Plans folder.	Annual inspections arranged through Northwest Invasive Plants Council (NWIPC) beginning in 2016, with control implemented beginning in 2017. Plan is evaluated through the course of the inspections and follow-up reporting. Version control table and cover page updated in 2018. No changes based on 2019 review. No changes required based on 2020 review. No changes based on 2021 review. Version control table and cover page updated in January 2023.
Metal Leaching and Acid Rock Drainage (ML/ARD) Management Plan (Appendix 9-1-11)	LWRS/Forests/EMLI	February 2023 (updated)	Original May 2015 via *MA* & *EMA* Permits Application; MEMPR and ENV March 6, 2017; *MA* & *EMA* joint 2017 Annual Report submitted March 2018; submitted to EAO on December 31, 2018 and with *MA* & *EMA* joint 2018 Annual Report submitted March 2019; submitted with *MA* & *EMA* joint 2019 Annual Report in March 2020; current version submitted with *MA* & *EMA* joint 2020 Annual Report in March 2021; internally via Management Plans folder. Current edition submitted via 2022 Annual Report; internally via Management Plans folder.	Plan is reviewed with every application to amend water quality discharge limits of PE-107835 and/or to amend geochemistry or mine plan related conditions of M-243 and amended based on outcomes from government reviews of those applications. The December 2018 update stemmed from the December 14, 2018 issuance of final authorizations for the 3800 tpd production increase. The March 2020 update included minor revisions to some sampling procedures. The Plan is also reviewed for *MA* & *EMA* joint Annual Report submissions, as there are extensive annual reporting requirements under it, and through the extensive monitoring under this plan. The 2020 review resulted in minor revisions to sampling procedures. No changes required based on 2021 review. Version control table and cover page updated in February 2023.
Mine Emergency Response Plan (Appendix 9-1-12)	MEMLI	February 2022	Original May 2015 via *MA* & *EMA* Permits Application; submitted to EAO on December 31, 2018 and with *MA* & *EMA* joint 2018 Annual Report submitted March 2019; submitted with *MA & EMA* joint 2020 Annual Report in March 2021; current version submitted with *MA & EMA* joint 2021 Annual Report in March 2022; internally via Management Plans folder.	Plan reviewed annually. Plan was updated based on the 2018 review, including updates to align with 2017 MEMPR Guidance (v1.4). No changes required based on 2019 review. The 2020 annual review resulted in updates to align with current safety standards and practices. In February 2022, the Plan was updated to include the current risk matrix and an incident report template. No changes required based on 2023 review.
Reclamation and Closure Plan (Appendix 4-1)	MEMLI	March 2023 (updated)	May 2015 via *MA* & *EMA* Permits Application; submitted to EAO on December 31, 2018; current addition distributed via 2020 Mine Plan and Reclamation Program Update (as Chapter 3) submitted July 2020; internally via Management Plans folder.	Content was updated based on the 2018 review to reflect constructed infrastructure rather than proposed, and to separate infrastructure within the M-243 permitted area from ancillary infrastructure located outside of that area. In 2020, the plan was updated as Chapter 3 of the 2020 Mine Plan and Reclamation Program Update (Pretium 2020b), including to address content requirements of *Mines Act* Permit M-243 Condition E.14. No changes required based on 2021 review. In 2022, the plan was updated, including to reflect changes associated with increased ore production.
Soils Management Plan (Appendix 9-1-20)	LWRS/Forests/EMLI	July 2020	May 2015 via *MA* & *EMA* Permits Application; submitted to EAO on December 31, 2018. Currently the Soils Management Plan is addressed through the Reclamation and Closure Plan.	Plan was implemented during construction, which was mostly completed by end of summer 2017. Plan was reviewed in 2018 and extracted from Chapter 5 MA/EMA Permit Application document and presented as a stand-alone Plan. In 2020 onwards, updates to soil management, mainly with respect to reclamation research, are addressed in the Reclamation and Closure Plan.

Brucejack Mine Management Plans	Relevant Regulatory Authority	Current Version Date (Revision Status)	Distribution Timing/Status	Reviews/Audits
Spill Response Plan (Appendix 9-1-13)	EMLI/ENV	March 2022	Original May 2015 via *MA* & *EMA* Permits Application; *MA* & *EMA* joint 2016 Annual Report submitted March 2017; *MA* & *EMA* joint 2017 Annual Report submitted March 2018; submitted to EAO on December 31, 2018 and with *MA* & *EMA* joint 2018 Annual Report submitted March 2019; submitted with *MA* & *EMA* joint 2019 Annual Report in March 2020; current edition submitted with *MA* & *EMA* joint 2021 Annual Report in March 2022; internally via Management Plans folder.	Formal spill response training exercises are conducted annually by third party consultant, Northwest Response Ltd. These sessions are delivered to personnel at all camps (i.e., Wildfire, Bowser, Knipple, and Brucejack), and target all rotations, including those on night shift. Mock hydrocarbon spill response drills are also carried out periodically. The site orientation, which all employees must attend, includes a spill response training component. Lessons learned from these activities were incorporated into the 2018 update. In February 2020, the Plan was updated to reflect changes in regulations, contact information and current practices at the mine site. In March 2021, relevant measures on newly added (in 2020) reagents were updated, as was mapping on charting potential spill flow along the road. In March 2022, the Plan was updated to incorporate changes from IAAC Information Request July 22, 2021 and reflect changes to contact information for IAAC and First Nations. No changes based on 2022 review.
Traffic and Access Management Plan (Appendix 9-1-14)	LWRS/Forests/EMLI	January 2023 (updated)	Original May 2015 via *MA* & *EMA* Permits Application; current edition submitted to EAO on December 31, 2018; internally via Management Plans folder. Current edition submitted via 2022 Annual Report; internally via Management Plans folder.	Augmented by the Standard Road Procedures document, most current issued version of which is December 2018. Reviews/evaluation ongoing through the road use. Updated based on 2018 review to reflect Operations phase use of the road. No changes required based on 2019 review. No changes required based on 2020 review. No changes required based on 2021 review. Version control table, cover page, and section 5.4 call out procedure updated in January 2023.
Vegetation Management Plan (Appendix 9-1-15)	LWRS/Forests/EMLI	February 2023 (updated)	Original May 2015 via *MA* & *EMA* Permits Application; current edition submitted to EAO on December 31, 2018; internally via Management Plans folder. Current edition submitted via 2022 Annual Report; internally via Management Plans folder.	Plan was implemented during construction, which was mostly completed by end of summer 2017. Version control table and cover page updated for 2018. Plan was reviewed in 2019 resulting in no changes. No changes required based on 2020 review. No significant construction planned moving forward that would entail additional vegetation management. No changes based on 2021 review. Version control table and cover page updates based on 2023 review.
Waste Management Plan (Appendix 9-1-16)	ENV	December 2021 (updated)	Original May 2015 via *MA* & *EMA* Permits Application; January 2017 edition submitted to ENV January 2017; *MA* & *EMA* joint 2017 Annual Report submitted March 2018; submitted to EAO on December 31, 2018 and with *MA* & *EMA* joint 2018 Annual Report submitted March 2019; current version submitted with *MA & EMA* joint 2021 Annual Report in March 2022; internally via Management Plans folder. Current edition submitted via 2022 Annual Report; internally via Management Plans folder.	Designated waste management coordinators and staff work to achieve compliance with Pretium's updated Waste Management Plan; this includes routine internal environmental/waste management inspections at each camp. Training sessions/presentations are delivered regularly to site personnel on maintaining good waste management practices and minimizing wildlife attractants. Version control table and cover page updated in 2018. No changes required based on 2019 review. No changes required based on 2020 review. In December 2021, the Plan was updated to reflect current operations and maintenance procedures. No changes based on 2022 review.
Waste Rock and Tailings Storage Facility – OMS Manual (Appendix 9-1-17)	EMLI	June 2021	Original May 2015 via *MA* & *EMA* Permits Application; November 2017 to MEMPR; *MA* & *EMA* joint 2017 Annual Report submitted March 2018; submitted to EAO on December 31, 2018 and with *MA* & *EMA* joint 2018 Annual Report submitted March 2019; submitted with *MA & EMA* joint 2019 Annual Report submitted March 2020; current version submitted with *MA & EMA* joint 2021 Annual Report in March 2022; internally via Management Plans folder.	Original Tailings and Waste Rock Subaqueous Deposition Management Plan replaced by Waste Rock and Tailings Storage Facility – OMS Manual. The OMS Manual reviewed annually and updated, as needed, to reflect changes as facility develops per requirements of M-243 Condition C.3(a)(i). WRTSF reviews also captured under M-243 requirements for an Annual Construction Report, and Code requirements for annual review by the EOR and an Independent Tailings Review Board. OMS Manual was updated by SRK Consulting in October 2018 to align with changes from the 3800 tpd production increase and related WRTSF design update. The OMS Manual was again updated in March 2020 to align with current surveys, regulations and changes to the company organizational chart. A review of the plan was again conducted in December 2020 and an updated version is anticipated to be completed in 2021. The OMS Manual was once again updated in June 2021 to align with current surveys, regulations and changes to the company organizational chart. A review of the plan was again conducted in 2022 and an updated version is anticipated to be completed in 2023.

Brucejack Mine Management Plans	Relevant Regulatory Authority	Current Version Date (Revision Status)	Distribution Timing/Status	Reviews/Audits
Water Management Plan – OMS Manual (Appendix 9-1-18)	LWRS/Forests/EMLI	February 2023 (updated)	Original May 2015 via *MA* & *EMA* Permits Application; updated OMS version via *MA* & *EMA* joint 2017 Annual Report submitted March 2018; submitted to EAO on December 31, 2018 and with *MA* & *EMA* joint 2018 Annual Report submitted March 2019; submitted with *MA* & *EMA* joint 2019 Annual Report submitted March 2020; submitted with *MA* & *EMA* joint 2020 Annual Report in March 2021; current version submitted with *MA* & *EMA* joint 2021 Annual Report in March 2022; internally via Management Plans folder. Current edition submitted via 2022 Annual Report; internally via Management Plans folder.	Original Water Management Plan has been replaced by the 'Operation, Maintenance and Surveillance Manual (OMS Manual) – Water Management Plan', which incorporates details of Operations water management (contact and non-contact water). Inspections under the plan are completed by site personnel in accordance with the plan. This Plan was updated in 2018 to reflect current status, including drawing revisions/updates. The Plan was again updated in March 2020 to reflect change of EOR from BGC to SRK and to align with revised regulations and practices. In February 2021, the plan was updated to reflect changes to the company organizational chart, roles and responsibilities table and maps. In February 2023, the plan was updated to reflect changes to the company organizational chart, roles and responsibilities tables and maps.
Wildlife Management Plan (Appendix 9-1-19)	LWRS/Forests/EMLI	February 2023 (updated)	May 2015 via *MA* & *EMA* Permits Application; current version submitted to EAO on December 31, 2018 and with *MA* & *EMA* joint 2018 Annual Report submitted March 2019; internally via Management Plans folder. Current edition submitted via 2022 Annual Report; internally via Management Plans folder.	Plan is implemented on an ongoing basis, with much of the most important aspects on preventing adverse impacts accomplished through implementation of the closely related Waste, Refuse Incinerator, and Goat Management Plans (last stemming from the Wildlife Management Plan), plus plans related to spills and water quality. The plan is also one of the key plans/documents under review of the Wildlife Advisory Committee (WAC). The Plan was reviewed and updated in December 2018 in response to an EAO inspection report received October 2018. No changes required based on 2019 review. No changes required based on 2020 review. No changes required based on 2021 review. The plan was reviewed and updated in 2022 in response to comments received from MFLNRO during the 2022 Wildlife Advisory Committee (WAC), internal and ERM review. Version control and table updates based on January 2023 review.
Additional Management Plans Per Other Provincial Authorizations and Requirements (refer to Appendix 3-1-2 for plans)				
Chromium Management Plan (Appendix 9-2-1)	ENV	February 2023 (updated)	Original to MEMPR and ENV March 6, 2017; updated version via *MA* & *EMA* joint 2017 Annual Report submitted March 2018; current edition submitted via *MA* & *EMA* joint 2018 Annual Report submitted March 2019; internally via Management Plans folder. Current edition submitted via 2022 Annual Report; internally via Management Plans folder.	Concentrations of total, dissolved and dissolved hexavalent Cr are monitored monthly in mine influent. Overall, the monitoring data indicate the CMP has been effective for chromium source control. Based on the 2018 review, the CMP was updated to reflect operational monitoring data and to align with changes from the 3800 tpd production increase approved December 14, 2018. No changes required based on 2019 review. No changes required based on 2020 review. No changes required based on 2021 review. Version control and table updates based on February 2023 review.
Closure Underground Water Quality Adaptive Management Plan (Appendix 9-2-2)	ENV	July 2020	New plan. Distributed via 2020 Mine Plan and Reclamation Program Update submitted July 2020.	Prepared as required by PE-107835 Condition 3.3. No changes required based on 2020 review. No changes required based on 2021 review. No changes required based on 2022 review.
Geohazards Management Plan (Appendix 9-2-3)	EMLI	October 2023 (updated)	Original May 2015 via *MA* & *EMA* Permits Application; submitted via *MA* & *EMA* joint 2016 Annual Report submitted March 2017; current version submitted with *MA* & *EMA* joint 2021 Annual Report in March 2022; internally via Management Plans folder. Current edition submitted via 2022 Annual Report; internally via Management Plans folder.	M-243 Condition C.9 requires annual review of geohazard management practices being implemented at the mine site by a Professional Engineer. No changes required based on 2019, 2020 or 2021 review. The plan was reviewed and updated by BGC in October 2023.
Ground Control Management Plan (Appendix 9-2-4)	EMLI	February 2023 (updated)	Original May 2015 via *MA* & *EMA* Permits Application; updated version via *MA* & *EMA* joint 2017 Annual Report submitted March 2018; submitted to EAO on December 31, 2018; *MA* & *EMA* joint 2018 Annual Report submitted March 2019; submitted with *MA* & *EMA* joint 2020 Annual Report in March 2021; current version submitted with *MA* & *EMA* joint 2021 Annual Report in March 2022; internally via Management Plans folder. Current edition submitted via 2022 Annual Report; internally via Management Plans folder.	Ground Control Management Plan is reviewed annually and updated as deemed necessary by a Professional Engineer, per requirements of M-243 Condition C.2(d). M-243 Condition C.2(m)(i) requires annual review of the underground workings by a Professional Engineer and C.2(m)(ii) requires a third-party audit of the Ground Control Management Plan by a Professional Engineer, beginning in 2018. The 2018 GCMP Audit was completed by BGC, and BGC also updated the GCMP during Q1 2019. The 2019 audit was completed by SRK, resulting in no required updates. The 2020 audit was completed by SRK and resulted in changes to operational procedures. The Ground Control Management plan was updated in January 2022 to reflect changes to current operational procedures. The Ground Control Management plan was updated in February 2023 to reflect changes to current operational procedures.

Brucejack Mine Management Plans	Relevant Regulatory Authority	Current Version Date (Revision Status)	Distribution Timing/Status	Reviews/Audits
Mountain Goat Management Plan (Appendix 9-2-5)	LWRS/Forests	January 2023 (updated)	Directly to FLNRORD and Wildlife Advisory Committee April 27, 2017; submitted via *MA & EMA* joint 2017 Annual Report submitted March 2018; current version submitted with *MA & EMA* joint 2020 Annual Report in March 2021; internally via Management Plans folder. Current edition submitted via 2022 Annual Report; internally via Management Plans folder.	Reviewed by FLNRORD and by Wildlife Advisory Committee (WAC). Plan is subject to ongoing review as deemed necessary by the WAC. The Plan was sent out for review to the WAC members in 2019 with comments received. The review process continued into 2020 and an updated version was finalized in June 2020. No changes required based on 2021 review. Version control table and cover page updates based on 2023 review.
Nitrogen Management Plan (Appendix 9-2-6)	ENV/EMLI	March 2023 (updated)	Original distributed as appendix of ML/ARD Mgmt Plan provided to ENV and MEMPR November 2016, as part of PE-107835 Amendment Application #4; *MA & EMA* joint 2017 Annual Report submitted March 2018; *MA & EMA* joint 2018 Annual Report submitted March 2019; 2020 Mine Plan and Reclamation Program Update submitted July 2020; current version submitted with *MA & EMA* joint 2021 Annual Report in March 2022; internally via Management Plans folder. Current edition submitted via 2022 Annual Report; internally via Management Plans folder.	Nitrogen audits under plan conducted minimum 6 times annually. Plan itself audited/reviewed each time water quality predictions and related nitrogen sources terms are to be updated. Based on the 2018 review, this plan was updated to reflect current operating conditions and changes associated with the 3800 tpd production increase approved December 14, 2018. Plan was reviewed and updated in 2020 to reflect current practices, including changes to production blasting methods. The Plan was again updated in 2021 to reflect current practices. Plan was reviewed and updated in 2023 to reflect current practices, including additional data from 2023 and changes in methodology utilized for calculating development powder factors and nitrogen loading to mine water.
Refuse Incinerator Management Plan (Appendix 9-2-7)	ENV	February 2023 (updated)	Original to ENV August 2016; updated version via *MA & EMA* joint 2017 Annual Report submitted March 2018; current edition submitted via *MA & EMA* joint 2019 Annual Report submitted March 2020; internally via Management Plans folder. Current edition submitted via 2022 Annual Report; internally via Management Plans folder.	Formal operator training on both incinerators are conducted at site by the manufacturer (Eco Waste Solutions) to relevant personnel (e.g., Waste Management Coordinators and Operators). Incinerator logs and daily routine inspections are used to monitor compliance with all relevant Plans, including but not limited to, the Refuse Incinerator Management Plan, Waste Management Plan and Air Quality Monitoring Plan. Based on 2018 review of this plan, it was determined that no update was required. The Plan was updated March 2020 to align with current permits, regulations, and on-site logistics/practices. A review of the plan later in 2020 resulted in no required changes. No changes required based on 2021 review. Version control and cover page updates based on 2023 review.
Subsidence Monitoring and Management Plan (Appendix 9-2-8)	EMLI	February 2023 (updated)	New plan. Distributed via 2020 Mine Plan and Reclamation Program Update submitted July 2020. Current edition submitted via 2022 Annual Report; internally via Management Plans folder.	Prepared as required by M-243 Condition D.13. No changes required based on 2021 review. Plan was reviewed and updated in 2023 to include update on monitoring, mining zones, and monitoring methods including version control and cover page updates.
Surface Erosion Prevention and Sediment Control Plan (Appendix 9-2-9)	EMLI	March 2015	Original May 2015 via *MA & EMA* Permits Application, as an appendix of the Construction Environmental Management Plan (CEMP)	Plan reviewed at least annually, as per M-243 Condition D.7. No changes required based on 2021 review. No changes based on 2022 review.
Ventilation Plan (Appendix 9-2-10)	EMLI	February 2022	Original prepared February 2018; 2020 update distributed via 2020 Mine Plan and Reclamation Program Update submitted July 2020 (Pretium, 2020b). Current edition submitted via *MA & EMA* joint 2021 Annual Report submitted March 2022; internally via Management Plans folder.	Prepared as required by MEMLI Senior H&S Inspector and as per relevant sections of the Health, Safety and Reclamation Code for Mines in BC (e.g., sections 3.4, 3.5, 6.33, 6.34, 6.36 and 6.37). In 2020, the Plan was updated based on changes to the mine plan. In February 2022, the Plan was updated to reflect changes to current operations. No changes based on 2022 review.

9.1.4 Other Management Plans

9.1.4.1 Discharge Management Plan

As described in Section 5.9, discharge quality from the WRTSF is managed through source control, the water treatment plant, and the sewage treatment plant. Source control includes measures from mine design and management via implementation of various management plans, including the ML/ARD Management Plan (Appendix 9-1-11), the Nitrogen Management Plan (Appendix 9-2-6), the Chromium Management Plan (Appendix 9-2-1), the OMS Manual - Water Management Plan (Appendix 9-1-18), and the WRTSF OMS Manual (Appendix 9-1-17). Mine site water management has effectively maintained WRTSF effluent quality, measured at site BJ 3.10, below discharge limits in PE-10835 or below FWAL guidelines for parameters without discharge limits.

BJ 3.10 water quality is sampled weekly, in accordance with PE-107835. Results are typically received from the analytical laboratory (ALS Environmental) within 2 weeks of the sample date. Pretium staff review BJ 3.10 water quality results when received from the analytical laboratory and if any results are above discharge limits, notifications are provided in accordance with condition 5.3 of PE-107835. A result that is above a discharge limit is investigated to determine the probable cause, and to determine and implement remedial actions, if necessary, to prevent similar non-compliance in the future.

BJ 3.10 water quality results are evaluated by Pretium staff to identify POPCs, and to determine if additional measures are required to manage POPCs, using a TRP, which is described in Section 5.9 and shown in a flowchart in Figure 5.9-1.

9.1.4.2 Construction Environmental Management Plan

There is no new surface construction proposed for the 4950 tpd Joint Application, therefore the Construction Environmental Management Plan (CEMP) has not been included. The CEMP is included as Appendix 6-G of the 2015 *MA/EMA* Permits Application.

9.1.4.3 Fugitive Dust Management Plan

Fugitive dust management is part of the existing Brucejack Mine Air Quality Management Plan, therefore a separate Fugitive Dust Management Plan has not been included in this application. The Brucejack Mine site is snow-covered for most of the year and typically wet during much of the brief summer months. Being an underground mine, the extent of surface disturbance is small; the primary potential source of fugitive dust from surfaces is roads and facility pads. During the infrequent and usually short duration periods of dry conditions at the mine site, road and pads watering is implemented.

9.2 Management Plans Reviews and Distribution

Pretium conducts reviews (internal and external) of the EMS component management plans on an ongoing basis, and updates and distributes management plans and associated review results as required/appropriate. Plan implementation inspections/audits and reviews of the plans themselves are scheduled specific to each management plan, with consideration of risk, as well as type, frequency and extent of monitoring (e.g., weekly water quality monitoring at the discharge location which verifies the effectiveness of all management plans that influence Brucejack Mine effluent quality).

Management plan implementation inspections/audits may be as frequent as weekly or semi-monthly. There are annual inspection requirements (via permit) for several of the plans, which – in addition to compliance/conformance outcomes – determine need for further evaluation and potential management plan updates. Updated component management plans are included in the Annual Reports, which are submitted to EMLI, ENV, Tsetsaut Skii km La Ha, Nisga'a Lisims Government, and Tahltan Central Government.

9.3 Expected Management Plan Update Requirements

Consistent with previous applications and reviews, any required updates to management plans for the proposed production increase will be completed post-review to incorporate changes resulting from the review.

Pretium currently anticipates that the following management plans and OMS manuals may require revisions following the 4950 tpd Joint Application review process:

- Metal Leaching / Acid Rock Drainage (ML/ARD) Management Plan – to reflect operational procedures, updated water quality predictions and revised trigger threshold levels as appropriate; the Chromium Management Plan (an appendix to the ML/ARD Management Plan) will also be updated to reflect paste backfilling procedures developed and to report the results of kinetic test work required by the plan;
- Nitrogen Management Plan – to reflect the increased mine development and production schedules as well as the associated water quality predictions, effluent permit conditions, management triggers, and water quality mitigation options;
- Subaqueous Waste Rock and Tailings Deposition Management OMS Manual – to reflect the updated waste rock and tailings deposition plan. As described previously, the production increase is not anticipated to affect waste rock dump stability or monitoring aspects of this OMS manual;
- Closure Underground Water Quality Adaptive Management Plan – to incorporate revisions to the groundwater and water quality models based on the increased mine production, and to revise discharge limits and applicable BC FWAL guidelines;
- Backfill Management Plan – to reflect higher through-put from the paste plant to ensure timely filling of stope voids; and
- Ventilation Management Plan – to reflect the addition of VR5.

The Reclamation and Closure Plan has been updated and is provided in Appendix 4-1.

While this list only includes management plans that Pretium anticipates will require revisions, as mentioned above, Pretium conducts reviews of the EMS component management plans on an ongoing basis, and updates and distributes management plans and associated review results as required/appropriate. Any plans requiring revisions that have not been listed above, will be captured and identified during regular reviews.

10. AUTHORS AND QUALIFIED PROFESSIONALS

Pretium / Newcrest personnel and consultants who provided technical input or other major contributions to this application are listed in Table 1.4-1 along with their primary roles and professional designations. Signed and sealed acknowledgements by the Qualified Professionals responsible for application technical chapters and information are provided below (presented in alphabetical order by last name) and ENV Declaration Forms are provided in Appendix 10-1. Technical reports included as appendices to the 4950 tpd Joint Application are signed and sealed by Qualified Professionals, as appropriate, within those reports.

Chapter 1 Appendices

Appendix 1-1: *Mines Act* Permit M-243 and Effluent Discharge Permit PE-107835

PROVINCE OF BRITISH COLUMBIA
MINISTRY OF ENERGY, MINES AND LOW CARBON INNOVATION

PERMIT

APPROVING MINE PLAN AND RECLAMATION PROGRAM

(Issued pursuant to section 10 of the *Mines Act* R.S.B.C. 1996, c. 293)

Permit: **M-243** Mine No: **0100270**

Issued to: **Pretium Resources Inc.**
Suite 2300, Four Bentall Centre
1055 Dunsmuir Street
PO Box 49334
Vancouver, BC
V7X 1L4

for work located at the:

Brucejack Mine

Issue Date	**Permit**
July 22, 2015	Approving Mine Plan and Reclamation Program

This permit supersedes and amends all previous versions of Permit M-243 issued pursuant to Part 10 of the Mines Act. All previously approved works systems are hereby transferred under this permit.

Amended at Victoria, British Columbia this 1st day of August in the year 2023.

J. Lowell Constable
Deputy Chief Permitting Officer
Major Mines Office

(This page is left intentionally blank)

PREAMBLE

The *Mines Act* Permit application, and applications for changes to approved works and conditions to Permit M-243, have been submitted to the Chief Permitting Officer, in accordance with Section 10(1) and/or 10(6) of the *Mines Act*, and Sections 10.1.2 and 10.1.18 of *the Health, Safety and Reclamation Code for Mines in British Columbia* (Code).

Where more than one version of information exists in the application, the most recent version must be considered the approved version unless otherwise stated or determined by the Chief Permitting Officer.

1. Approving Mine Plan and Reclamation Program (Issued July 22, 2015)

1.1 Application entitled, '*Brucejack Gold Mine: Application for Mines Act and Environmental Management Act Permits*', prepared by Pretium Resources Inc., dated May 2015.

1.2 Report entitled, '*Brucejack Gold Mine Project: Metal Leaching and Acid Rock Drainage Management Plan*', prepared by Pretium Resources Inc., dated June 30, 2015.

1.3 Memorandum entitled, '*Brucejack Project MA/EMA Permitting Phase – Responses to Information Requests from MEM & MOE – Groundwater Quality and Quantity Monitoring Plan*', prepared by BGC Engineering Inc., dated June 19, 2015.

1.4 Memorandum entitled, '*Brucejack Project MA/EMA Permitting Phase – Responses to Information Requests from MEM & MOE – Part 1 of 2*', prepared by BGC Engineering Inc., dated June 19, 2015.

1.5 Memorandum entitled, '*Brucejack Project MA/EMA Permitting Phase – Responses to Information Requests from MEM & MOE – Part 2 of 2*', prepared by BGC Engineering Inc., dated June 19, 2015.

1.6 Report entitled, '*Groundwater Monitoring and Sampling Protocol – Brucejack Mine; Revision 3*', prepared by Pretium Resources Inc., dated June 2015.

1.7 Letter entitled, '*Response to BC Ministry of Energy and Mines 'Information Requirements' and 'Clarifications' regarding underground geotechnical aspects of the Brucejack Project's Application for Mines Act and Environmental Management Act Permits*', prepared by BGC Engineering, dated June 18, 2015.

1.8 Report entitled, '*Brucejack Gold Mine Project - Invasive Plants Management Plan*', prepared by Pretium Resources Inc., dated July 2015.

1.9 Confidential Memorandum entitled, '*Brucejack Mine Project Mines Act Permit Application – Reclamation Cost Estimate*', prepared by ERM dated June 22, 2015.

1.10 Report entitled, '*Brucejack Gold Mine Project Wildlife Management Plan*', prepared by ERM dated July 2015.

2. Approving Groundwater Monitoring Plan (Issued August 26, 2015)

2.1 Report entitled, '*Brucejack Gold Mine Project – Location, purpose, timing and monitoring schedule for monitoring wells to be installed to augment the Water Management Plan per Mines Act Permit M-243 Section D Part 4(c) – REV 1*', prepared by Pretium Resources Inc., dated August 21, 2015.

3. Approving Updated Brucejack ML/ARD Management Plan (Issued September 9, 2015)

3.1 Report entitled, '*Brucejack Gold Mine Project – Metal Leaching and Acid Rock Drainage Management Plan*', prepared by Pretium Resources Inc., dated September 8, 2015.

4. Approving Temporary PAG Waste Rock Stockpile and Non-PAG Quarry (Issued March 17, 2016)

4.1 Application entitled, '*Request for Authorization of Temporary Surface PAG Waste Rock Stockpile, Mines Act Permit M-243, Brucejack Mine*', prepared by Pretium Resources Inc., dated October 18, 2015.

4.2 Application entitled, '*Application for Modification of Km 72 NPAG Quarry, Permit M-243, Brucejack Mine*', prepared by Pretium Resources Inc., dated November 3, 2015.

5. Approving Changes for Disturbance Area and Construction Water Treatment Plant (Issued August 4, 2016)

5.1 Application entitled, '*Proposed Changes to Approved Disturbance Area, Mines Act Permit M-243, Brucejack Gold Mine – Amendment Application #2*', prepared by Pretium Resources Inc., dated April 11, 2016.

5.2 Application entitled, '*Application for Approval of Mine Water Treatment Plant Process Change for Nitrite Treatment*', prepared by Pretium Resources Inc., dated April 25, 2016.

5.3 Report entitled, '*Brucejack Gold Mine 2016 Freshet Water Management Plan*', prepared by Pretium Resources Inc., dated March 2016.

6. Approving PAG Waste Rock Exposure Extension, Sludge Deposition with Tailings In Brucejack Lake and Chromium Management Plan (Issued April 3, 2017)

6.1 Report entitled, '*Brucejack Mine: Proposed Extension for Waste Rock Storage on Surface*', prepared by Pretium Resources Inc., dated November 10, 2016.

6.2 Report entitled, '*Brucejack Gold Mine: Assessment of Long-Term Sludge Stability for In-Lake and Underground Deposition*', prepared by Pretium Resources Inc., dated December 19, 2016.

6.3 Report entitled, '*Chromium Management Plan*', prepared by Pretium Resources Inc., dated February 23, 2017.

6.4 Report entitled, '*Metal Leaching and Acid Rock Drainage Management Plan*', prepared by Pretium Resources Inc., dated March 2017.

6.5 Report entitled, '*Operation, Maintenance and Surveillance Manual: Brucejack Gold Mine Subaqueous Waste Rock and Tailings Deposition; VERSION 04*', prepared by Pretium Resources Inc., dated March 2017.

7. Approving Mine Plan and Reclamation Program for Increased Production Rate and Waste Management (Issued December 14, 2018)

7.1 Application entitled, '*3800 tpd Amendment Application for Permits M-243 and PE-107835*', prepared by Pretium Resources Inc., dated December 2017.

7.2 Report entitled, '*Brucejack Gold Mine: Updated Subaqueous Waste Rock Dump Design*', prepared by SRK Consulting, dated October 2018.

7.3 Letter entitled, '*Brucejack Gold Mine, Mine No. 0100270 MA Permit M-243 Section D.1 (d)*', prepared by Pretium Resources Inc., dated March 8, 2018.

8. Approving West Zone Ramp, Additional Stope Development, and Underground Exploration (Issued December 18, 2020)

8.1 Application entitled, '*Mines Act Permit M-243 Amendment Application: Permit Boundary Amendment*', prepared by ERM Worldwide Group Ltd., dated August 2020.

8.2 Report entitled, '*OMS Manual - Water Management Plan*' prepared by SRK Consulting Inc., dated March 2020.

8.3 Report entitled, '*Brucejack Gold Mine: 2020 Groundwater Model Review and Update*', prepared by Lorax Environmental, dated July 20, 2020.

8.4 Report entitled, '*Brucejack Gold Mine Ground Control Management Plan – Version 7*', prepared by Pretium Resources Inc., dated October 2020.

8.5 Report entitled, '*Production Ventilation Plan Brucejack Gold Mine*', prepared by Pretium Resources Inc., dated July 10, 2020.

9. Approving Permitted Mine Area (PMA) Expansion for Future Access Road Realignment km 72 Ramp (Issued November 14, 2022)

9.1 Application entitled, '*Permit M-243 Brucejack Mine – Amendment Application to Increase Permitted Mine Area for Future Brucejack Access Road km 72 Ramp Realignments*', prepared by Pretium Resources Inc., dated December 2, 2021.

9.2 Document entitled, '*Geohazards Management Plan Revision 1*', prepared by Pretium Resources Inc., dated December 2016.

9.3 Report entitled, '*Brucejack Access Road 72 km Glacier Ramp Design Basis*', prepared by Onsite Engineering Ltd., dated August 19, 2022.

10. Approving Permitted Mine Area Change (Issued August 1, 2023)

10.1 Application entitled, '*M-243 PMA Expansion Application – Amendment Application #9 Area B'*, prepared by Pretium Resources Ltd., dated July 4, 2023.

This permit contains the requirements of the Ministry of Energy, Mines and Low Carbon Innovation (EMLI). It also is compatible, to the extent possible, with the requirements of other provincial ministries. However, nothing in this permit limits the authority of other provincial ministries to set other conditions, or to act independently, under their respective permits and legislation.

The mine is located within the consultative territory of Tsetsaut /Skii-km Lax Ha and portions of the mine permitted area are located in the Nass Area as defined in the Nisga'a Final Agreement. Tsetsaut/ Skii-km Lax Ha, Nisga'a Lisims Government and Tahltan Central Government have been consulted with respect to this permit and have expressed their interests regarding potential concerns to their asserted or established rights.

CONDITIONS

The Chief Permitting Officer hereby approves the Mine Plan and Reclamation Program as submitted in the applications, subject to compliance with the following conditions:

A. General

1. Compliance with *Mines Act* and Code

The Permittee must ensure all work is in compliance with all sections and parts of the *Mines Act* and the Health, Safety and Reclamation Code for Mines in B.C. (Code), and the owner, agent or manager (Permittee) must obey all orders issued by the Chief Inspector or their delegate.

2. Departure from Approval

The Permittee must notify the Chief Inspector of Mines (Chief Inspector) in writing of any intention to depart from the approved Application(s) and this *Mines Act* permit (M-243) to any substantial degree, and must not proceed to implement the proposed changes without the written authorization of the Chief Inspector.

3. Permit Approval

(a) The Permittee is authorized under this permit (M-243) for the following activities:

(i) Development, including surface disturbance and works and management buffers associated with 19 km of the Transmission Line extending southward from the Mine Site, within the area encompassing approximately 702 Ha as outlined in Figure 1a and 1b (Permitted Mine Area), which includes management buffers around the approved disturbance; and

(ii) Ore production rate must not exceed an average annual 1,387,000 tonnes on a calendar year basis.

4. Permit

This Permit is not transferable or assignable.

5. Maintenance of Mine

The Permittee must maintain mine facilities and infrastructure in a manner to meet design objectives and environmental protection and reclamation requirements.

6. Reports to be signed by a Qualified Professional

Unless otherwise specified in permit conditions, all reports required to be submitted under this permit the Permittee must ensure are reviewed and signed by a Qualified Professional with applicable experience and registered in the province of British Columbia.

7. Responsibility to Reclaim

Any outstanding reclamation associated with Reclamation Permit MX-1-842 that exists within the permitted mine area for the Brucejack Gold Mine defined in Figure 1a and Figure 1b is the responsibility of the Permittee under the terms and conditions of this permit.

8. First Nations Reporting Requirements

Unless otherwise requested, the Permittee must provide to the Tsetsaut/Skii-km Lax Ha, Nisga'a Lisims Government and Tahltan Central Council Government all material reports and plans relevant to this permit, including annual monitoring reports and material changes to the approved Reclamation and Closure Plan.

9. Compliance Status Report

The Permittee must track compliance status of all permit conditions, inspection orders or advisories in a form acceptable to the Chief Inspector. The Permittee must maintain a tracking table on site, and ensure it is revised when compliance changes or as required by the Chief Inspector. The Permittee must ensure that the tracking table is available at the mine site at all times and to a Mines Inspector upon request. An annual Compliance Status report must be submitted to the Chief Inspector by March 31st and must include a summary of outstanding non-compliance issues and an action plan, to the satisfaction of the Chief Inspector, for meeting compliance.

B. Health and Safety

1. Mine Emergency Response Plan (MERP)

(a) The Permittee must update the Mine Emergency Response Plan (MERP) The Permittee must keep the MERP up to date and file updates with the Chief Inspector, and make the updated MERP available at the mine site at all times.

(b) The Permittee must ensure that mine site employees and contractors are knowledgeable and accountable for fulfilling the actions of the MERP.

C. Geotechnical

1. General

(a) The Permittee must ensure that all geotechnical/designs, specifications, work plans, monitoring requirements and reports required to be prepared under Section (C) are signed by a Professional Engineer and are submitted to the Chief Inspector.

(b) The Permittee must ensure that all geotechnical/designs, specifications, work plans, monitoring requirements and reports required to be prepared under section (C) are maintained on site and made available to any Inspector of Mines upon request.

(c) The Permittee must ensure all construction is completed under the supervision of a Professional Engineer and that sufficient field reviews have been conducted to ensure that all construction and facilities are built in conformance with the design, accepted engineering practices and the Code.

(d) The Permittee must ensure that recommendations by a Professional Engineer relating to health and safety, geotechnical stability or environmental protection are followed unless a suitable alternative course of action is approved in writing by a Professional Engineer.

(e) The Permittee must submit an Advice of Geotechnical Incident form to the Chief Inspector for any geotechnical incident that is classified as a dangerous occurrence or any other incident as described in the current EMLI Advice of Geotechnical Incident form.

2. Underground Mine

(a) The Permittee must maintain an up-to-date mine design that includes computer models, drawings, calculations, specifications, and written descriptions of:

(i) The geometry of all existing and proposed excavations,
(ii) The geologic, hydrogeologic and geotechnical conditions affecting the mine, and
(iii) Excavation design and ground support design that considers stress, structure and rockmass conditions.

(b) The mine design must be periodically, at a minimum of annually, updated to reflect site experience and the actual geological, hydrological and geotechnical conditions encountered.

(c) The Permittee must ensure the dimensions of all excavations and pillars are within nominal tolerances per the recommendation of a Professional Engineer.

(d) Ground Control Management Plan

The Permittee must implement the Ground Control Management Plan (GCMP). The GCMP must be reviewed annually by a Professional Engineer and updated as required. The Permittee must submit the updated GCMP to the Chief Inspector within 60 days of being issued, and it must include (but is not limited to) the following components:

(i) Ground control program roles, responsibilities, accountabilities, implementation, records and communications,
(ii) Design basis information and assumptions used to develop the mine design and the ground control program,
(iii) Geological model for the mine,
(iv) Hydrogeological model for the mine,
(v) Geotechnical (rock mechanics) model for the mine including stress, structure and rockmass,
(vi) Historical experience,
(vii) Mine design including mining methods, and excavation dimensions, pillar dimensions, stope sequencing, etc.; and criteria used in dimensioning of excavations and pillars,
(viii) Water control measures including specific precautions to be taken where bodies of water, water bearing structures, overburden, tailings etc., may inundate the mine workings,
(ix) Ground support systems and materials to be employed,
(x) Criteria used in selection, dimensioning, spacing and extent of ground support,
(xi) Standards and procedures to ensure worker safety including,
(xii) Minimum ground support standards to be employed at Mine,
(xiii) Blasting methods,
(xiv) Employee procedures and training,
(xv) Monitoring program to verify acceptable performance, detect early signs of instability, and confirm design basis information and assumptions,
(xvi) QA/QC program,
(xvii) Risk management, and
(xviii) Ground Control Management Plan reviews, audits, and scheduled update program.

(e) The Permittee must install ground support in new and rehabilitated excavations in accordance with the recommendations of a Professional Engineer.

(f) Mining-Backfill Standard Operating Procedure (SOP)

The Permittee must implement and maintain a Mining-Backfill Standard Operating Procedure (SOP). The Permittee must ensure the Mining Backfill SOP be reviewed annually by a Professional Engineer and updated as required. The Mining Backfill SOP must consider (but is not limited to) the following components:

(i) Barricade and berm design for anticipated loading conditions;
(ii) Procedures for determining suitable barricade location;
(iii) QA/QC procedures for constructed barricades;
(iv) Design rationale for minimum strength requirements for operating beside and underneath backfill at the design dimensions;
(v) Prescribed fill rates within stopes;
(vi) Paste line flushing procedures;
(vii) Procedures to ensure tight backfill has occurred,
(viii) Safe filling procedures that include safe worker setback distance from active paste pours, and
(ix) QA/QC backfill testing requirements.

(g) The Permittee must ensure that no placement of paste backfill into a mined void proceeds unless the fill retention barricades constructed for the placed paste backfill are inspected and approved by a Professional Engineer.

(h) Monitoring

(i) The Permittee must maintain a geotechnical model of the underground openings that record the stress conditions, structure and rock mass in all headings and stopes.

(ii) The Permittee must conduct performance testing on installed ground support to ensure performance is in accordance with design values. The Permittee must ensure quantifiable performance objectives provide triggers for when rehabilitation of ground support is required.

(i) The Permittee must maintain a Ground Control Log Book that must be available at any time at the mine site to any Mines Inspector and includes, but is not limited to, the following information:

(i) Records of damaged, loaded, or failed support;
(ii) Areas of ground support non-conformance to design;
(iii) Records of working ground such as cracks, noise, movement, or other signs of instability;
(iv) Records of uncontrolled falls of ground;

(v) Unusual or unexpected geological, hydrogeological and geotechnical conditions;

(vi) Identification of ground control concerns, coupled with a plan for mitigation/remediation and prioritization; and

(vii) A record of the implementation of the mitigation/remediation to address the concern in C.2(i)(vi).

(j) The Permittee must monitor the strength of the paste backfill through laboratory or in-situ testing methods and ensure that no mining occur in areas below or adjacent to where low strength fill is encountered.

(k) The Permittee must ensure that the Ground Control Log Book is read and signed each day by the shift boss and the Mine Manager, or a mine engineer designated by the Mine Manager.

(l) The Permittee must ensure that in the event of mining induced seismicity, all mining must immediately cease until an observation, management and surveillance plan specific to mining in a mining induced seismically active area is submitted to the Chief Inspector and approved. The plan must provide measures to monitor micro seismicity and mitigate rock burst potential.

(m) Reporting

(i) The Permittee must ensure an annual review of the underground workings is undertaken by a Professional Engineer, and observations and recommendations made during the review are summarized in a report and submitted to the Chief Inspector by March 31 of the year following the inspection.

(ii) Starting in 2018, and every four years thereafter, or at the discretion of the Chief Inspector, the Permittee must ensure third party audits of the Ground Control Management Plan be conducted by a Professional Engineer and that they include a review of the instrumentation/monitoring program, QA/QC testing, stress management and pillar performance, and performance of installed ground support.

(iii) Starting in 2021, and every four years thereafter, or at the discretion of the Chief Inspector, the Permittee must ensure third party audits of the paste backfill operations be conducted by a Professional Engineer and that they include plant operations, paste reticulation system and paste placement procedures.

3. Subaqueous Waste Rock and Tailings Storage Facility (WRTSF)

(a) Operations

(i) The Permittee must implement the Subaqueous Waste Rock and Tailings Storage Facility Operation, Maintenance, and Surveillance Manual (OMS Manual; Document 6.5). The Permittee must ensure the OMS manual is reviewed annually and updated, as needed, to reflect changes in status as the facility develops.

(ii) The Permittee must ensure all employees and contractors involved in the operation of the WRTSF are trained in the implementation of the OMS Manual and that records of the training be maintained on site.

(iii) The Permittee must ensure that all subaqueous placement of tailings is to be performed under the guidance of a Professional Engineer.

(iv) The Permittee must assign a qualified person to monitor dumping and to provide a daily work schedule that shows the locations and quantities of waste rock to dump. No dumping of material must occur unless approved by the qualified person.

(v) The Permittee must ensure that no weak, cohesive materials or snow be dumped within the ultimate design limits of the subaqueous waste rock dump area, with the exception that high fines (cohesive) materials may be placed under the direction of the qualified person in areas approved by the Engineer of Record. The Permittee must ensure the locations, total volume and percentage (with respect to total placed) material of the high fines content is documented and included in the semi-annual and annual reports.

(vi) The Permittee must ensure any weak, cohesive materials or snow that is dumped outside the ultimate design limits of the WRTSF, be documented (locations and quantities) and included in the applicable semi-annual and annual reports.

(vii) The Permittee may, following standard operating procedures set in the OMS manual, and as outlined in Document 7.2, use a conveyor, excavator, or remotely operated vehicle to place waste rock into the ponded portion of the WRTSF.

(viii) The Permittee must develop an operational setback and delineation of high risk zone, including the following:

(a) The operational setback distance at the crest is defined with a Factor of Safety FoS > 1.1 for short term analysis of deep seated failures and areas with less than a FoS of 1.1 are identifiable as a high-risk zone;
(b) The zone must be clearly marked at all times;
(c) No personnel must work alone within this zone at any time;
(d) A clear, unobstructed escape route for equipment working within this zone must be maintained;
(e) Personal protective equipment, rescue equipment, communication equipment must be present at the location of work for all personnel working within the zone;
(f) At minimum a 10m operational setback distance must be maintained; and
(g) Prior to work occurring within the high risk zone, the area must be inspected and deemed safe by a Qualified Professional following all recommendations of the Engineer of Record.

(ix) The Permittee must implement an earthquake monitoring system with an alarm to trigger evacuation of personnel from the dump in the event of an earthquake.

(b) Monitoring and Reporting

(i) The Permittee must monitor dump crest movement and implement a failure alert procedure on all active waste dumps and closed high consequence dumps.

(ii) The Permittee must install instrumentation to monitor the rate of settlement of the subaqueous waste rock dump. Reports of the settlement rates are to be made available to the Mine Inspector upon request.

(iii) The Permittee must install a water level gauge or other suitable pond level monitoring system to monitor Brucejack Lake water level.

(c) Annual Construction Progress Report

The Permittee must submit an annual construction progress report to the Chief Inspector by March 31 of that year, on the construction and monitoring of the WRTSF. The Permittee must ensure the report includes:

(i) A review of construction documentation,
(ii) Rock deposition advancement,
(iii) A discussion detailing any potential amendments to original design based on field observations,
(iv) Recommendations for the placement of material in all weather conditions, and
(v) Confirmation the report was reviewed by the Engineer of Record.

(d) Annual Review of WRTSF

(i) The Permittee must ensure that an annual review of the WRTSF is conducted by a Professional Engineer and a report submitted to the Chief Inspector until 2021.

(ii) Starting in 2022, and every five (5) years thereafter, the Permittee must ensure that a review of the WRTSF is conducted by a Professional Engineer and a report submitted to the Chief Inspector.

4. Surface Water Ponds, Ditches and Diversion

(a) The Permittee must not commence construction of surface water ponds and ditches that carry mine-influenced water or diversion channels until issued for construction (IFC) drawings, signed by a Professional Engineer, are submitted to the Chief Inspector. This condition does not apply to temporary diversion channels required to facilitate construction.

(b) The Permittee must ensure that water surface ponds, ditches and diversion channels are designed to convey the design flood without overtopping or side slope failure, and with adequate armour or lining to prevent significant erosion.

(c) Ponds must be designed with a minimum 0.5 m freeboard under the design flood. The design flood must be chosen with consideration of the consequence of failure, and duty life of the ponds, but must be no less than the 1:200 year peak flow event.

(d) The Permittee must submit an 'As-Built' report to the Chief Inspector for all surface water ponds, ditches and diversion channels. The Permittee must ensure that the report certifies that each facility has been constructed in accordance with the design and the applicable guidelines.

(e) The Permittee must implement the Operations Maintenance and Surveillance Manual for the Contact Water Pond. The Permittee must ensure the OMS manual is reviewed annually and updated, as needed, to reflect changes in status as the facility develops.

(f) The Permittee must include all surface water ponds, ditches and diversion channels in an annual inspection by a Professional Engineer of water management facilities on the mine site. The annual inspections must be documented and inspection reports must be maintained onsite and provided to any inspector upon request.

5. Temporary Soil, Overburden, Rock, and Organic Material Stockpiles

The Permittee must ensure that the temporary soil, overburden, rock, and organic materials stockpiles are designed by a Professional Engineer and builtin accordance with the designs.

6. Borrow and Quarry Excavations

The Permittee must ensure that borrow and quarry excavations are designed by a Professional Engineer and developed in accordance with the designs.

7. Mine Site Roads

(a) The Permittee must ensure that all new mine roads are constructed in accordance with the designs and recommendations prepared by a Qualified Professional.

(b) The Permittee must ensure that all new roads with cut or fill slopes exceeding 6 m in height or located on terrain that can be classified as moderate (or higher) likelihood of initiating a landslide are designed by a Professional Engineer.

(c) The Permittee must ensure that all roads are reviewed at least every five years by a Qualified Professional. The Permittee must document the review and any recommendations and maintain a copy on site and provide it to an Inspector of Mines upon request.

(d) The Permittee must ensure that all roads are operated, maintained, and inspected in accordance with acceptable industry standards and guidelines.

8. Mine Site, Plant, Shop, and Other Infrastructure Foundations

(a) The Permittee must ensure that all building foundation designs address bearing capacity, potential settlement, and any necessary foundation preparation or treatment.

(b) The Permittee must ensure an inspection of the prepared excavation prior to the placement of permanent foundations is completed.

9. Geohazards Assessment

(a) The Permittee must develop and implement a Geohazards Management Plan. The Permittee must ensure that the plan is developed by a Qualified Professional. The Permittee must manage the geohazards associated with surface works in accordance with the plan. The plan must include mapping, an assessment of potential geohazards, and identification of risks prior to construction of the associated surface works.

(b) The Permittee must ensure a Qualified Professional conducts an annual review of the geohazard management practices being implemented by mine personnel at the mine site. The Permittee must provide the results of this inspection in an annual report to the Chief Inspector by March 31 of the year following the inspection.

D. Protection of Land and Watercourses

1. Environmental Management System

(a) The Permittee must maintain and implement an Environmental Management System (EMS) consisting of Environmental Management Plans (EMPs) and Standard Operating Procedures (SOPs). The EMS must reference relevant policies and establish proactive procedures to provide direction for effective operational management and monitoring on-site.

(b) The Permittee must audit the EMS annually, revise it as soon and as often as required, and make it available to a Mines Inspector at the mine site at all times. The findings of the annual audit of the EMS must be reported in the Annual Reclamation Report.

(c) The Permittee must ensure that mine site employees and contractors are knowledgeable and accountable to act consistently with the requirements of the EMPs and SOPs that form the EMS.

2. Environmental Manager

(a) The Permittee must ensure that an Environmental Manager is assigned.

(b) The Environmental Manager must have the authority to implement remedial actions as may be necessary to ensure maintenance of environmental standards and permit requirements. If suspension of construction or operations occurs due to environmental concerns, the Permittee or Environmental Manager must immediately notify the Chief Inspector.

3. Metal Leaching (ML) and Acid Rock Drainage (ARD)

(a) General

(i) The Permittee must ensure all materials with the potential to generate ML/ARD are placed in a manner that minimizes the production and release of metals and contaminants to levels that assure protection of environmental quality.

(ii) Unless otherwise approved, The Permittee must ensure all plans for the prediction, and if necessary, the prevention, mitigation and management of metal leaching and acid rock drainage are prepared in accordance with the *Guidelines for Metal Leaching and Acid Rock Drainage at Minesites in British Columbia* (1998).

(iii) The Permittee must ensure no changes are made to the criteria for ML/ARD definition, waste handling procedures, mitigation strategies, or materials monitoring program without the approval of the Chief Inspector.

(b) Definition of Potentially ARD Generating (PAG) and Metal Leaching (ML) Materials

All waste rock, quarry rock, borrow materials and tailings must be considered PAG if NP/AP is < 2, where AP is calculated from total sulphur and NP is calculated from total carbon.

(c) Mine Materials Handling and ML/ARD Mitigation

(i) The Permittee must ensure only non-PAG materials are used for construction purposes.

(ii) Prior to their use, the Permittee must ensure representative samples of quarry and borrow materials used for construction are tested and characterized in accordance with the ML/ARD Management Plan for their potential to generate ML/ARD.

(iii) The Permittee must ensure all waste rock generated from surface or underground development is backfilled in the underground workings, below the ultimate flood limit of the workings, or deposited in Brucejack Lake.

(iv) The Permittee must ensure all PAG waste rock deposited in Brucejack Lake is covered with a minimum 1 m water cover.

(v) The Permittee must ensure waste rock stored temporarily on surface, within the mine contact water collection system, for no longer than 2 years. Permanent disposal of waste rock on surface is not permitted.

(vi) The Permittee must ensure all tailings are either backfilled underground or deposited in Brucejack Lake.

(vii) The Permittee must ensure sludge generated from the Operations Water Treatment Plant is comingled with tailings and deposited in Brucejack Lake at a mixing ratio not to exceed 2% sludge by dry weight.

(viii) Underground co-disposal of Operations Water Treatment Plant sludge with cemented paste tailings is not permitted until such time as the Permittee can demonstrate the long term stability of these materials and an updated ML/ARD Management Plan and Subaqueous Waste Rock and Tailings Deposition OMS Manual is provided to the Chief Inspector for review and approval.

(ix) The placement of sludge from the Operations Water Treatment Plant in the underground workings is prohibited until such time the Permittee can demonstrate the long-term geochemical stability is demonstrated and an updated ML/ARD Management Plan and Subaqueous Waste Rock and Tailings Deposition OMS are provided to the Chief Inspector for review and approval.

(d) ML/ARD Operational Monitoring

(i) The ML/ARD Management Plan is approved and must be implemented. The Permittee must ensure no changes are made to the plan without the approval of the Chief Inspector.

(ii) The Permittee must ensure all personnel involved in waste rock and tailings generation and handling are trained and kept up to date on the content and implementation requirements of the ML/ARD Management Plan and the Subaqueous Waste Rock and Tailings Deposition OMS.

(iii) The Permittee must maintain an inventory of waste rock, quarry rock, borrow materials, exposed rock units in the underground workings, tailings products and water treatment plant sludge generated, including (as appropriate) information on source, composition, quantity of material, disposal location, elevation (meters), depth of water cover, and date of placement. This inventory must be kept on site and be made available to any Mines Inspector upon request.

(iv) Concurrent with mine development and operations, the Permittee must characterize excavated materials produced and mine surfaces exposed, including waste rock, quarry rock, borrow materials, exposed rock units in the underground, tailings products and generated water treatment plant sludge to determine ML/ARD generating potential, validate pre-mining predictions, guide material management decisions, confirm effectiveness of waste handling procedures, and determine the need for mitigation and contingency measures that ensure environmental protection.

(v) The Permittee must maintain a record of waste rock placed within the platform and active face areas of the waste rock dump. The record must include information on the type, amount and exposure time (in months) of waste rock prior to submergence in Brucejack Lake. The record must be kept on site and be made available to any Mines Inspector upon request. The record must be reported in the Annual Reclamation Report.

(e) Analytical Requirements

(i) The Permittee must present analytical QA/QC results in the Annual Reclamation Report.

(f) ML/ARD Reporting

(i) The Permittee must report results of the ML/ARD analytical testwork (including raw data, sample descriptions, analytical QA/QC, and materials inventory) and underground geologic mapping in the Annual Reclamation Report. Any significant changes or trends must be discussed, and implications for materials handling must be identified.

4. Water Management and Monitoring

(a) Water Management

(i) The Permittee must obtain any necessary permits and licenses for water diversion and discharge.

(ii) The Permittee must ensure water from the underground workings is collected and directed to water treatment.

(iii) The Permittee must ensure that water from the Contact Water Pond is collected and either directed to water treatment or to Brucejack Lake through the direct discharge line, as per the Contact Water Pond OMS manual required as a condition of this permit.

(b) Groundwater

(i) The Permittee must ensure the Operation, Maintenance and Surveillance Manual: Mine Site Surface Water Management Facilities is kept up to date, reviewed annually, revised as soon and as often as required and is made available to an Inspector at the mine site at all times. Updated versions of the manual must be submitted to the Chief Inspector.

(ii) The Permittee must ensure updates to the post-closure groundwater elevation predictions be provided with each Five Year Mine Plan Update, commencing July 31, 2020. Any changes to predicted post-closure groundwater levels must be used to revise the ML/ARD Management Plan and the Water Management Plan, as required.

(c) Chromium Management Plan

(i) The Permittee must implement the Chromium Management Plan (Document 6.3).

(ii) The Permittee ensure the Chromium Management Plan is kept up to date, reviewed annually, revised as soon and as often as required and made available to an Inspector at the mine site at all times. The findings of any investigations undertaken and any significant changes to the plan must be reported in the Annual Reclamation Report.

(iii) The Permittee must ensure that mine site employees and contractors are knowledgeable and accountable to act consistently with the requirements of the Chromium Management Plan.

(d) Monitoring and Reporting

(i) The Permittee must monitor and track changes to mine site surface water and groundwater quality and quantity from the underground workings (including pumping rate of water into and out of the underground workings), groundwater monitoring wells, Contact Water Pond, and tailings supernatant. The Permittee must ensure the program is capable of providing early warning about the onset of ARD or an increase in contaminant loading and provide refined predictions regarding the post-closure groundwater elevation.

(ii) The Permittee must ensure detection limits are sufficient to compare to provincial water quality guidelines and permit requirements established by the British Columbia Ministry of Environment.

(iii) The Permittee must ensure an effective QA/QC program for mine site contact water is implemented.

(iv) The Permittee must ensure monitoring results of water quality and water quantity, including interpretation of the results, are kept up to date in a dedicated database available for review by a Mines Inspector and reported in the Annual Reclamation Report.

(v) The Permittee must ensure that the Annual Reclamation Report includes a table comparing relevant monitoring and testwork data to source term concentrations used in water quality predictions. The Permittee must ensure implications of the results for source term refinement, water quality mitigation and adaptive management is discussed in the report.

(e) Water Quality Predictions

During operations, the Permittee must track water quality and flow monitoring data to enable validation and refinement of water quality predictions based on site-specific monitoring information. The Permittee must ensure water quality model updates is provided in every 5 Year Mine Plan update thereafter, or more frequently as necessary to inform mine planning and mitigation design and engineering.

5. Closure Underground Water Quality Adaptive Management Plan

The Permittee must implement an appropriate monitoring program with water quality triggers and management actions that will be used to ensure the groundwater discharging from the underground workings during post-closure is protective of receiving environment water quality.

6. Water Treatment

(a) Operations

(i) The Permittee must ensure the Operations Water Treatment Plant Operations and Maintenance Manual (OWTP OMS) is kept up to date, reviewed annually, revised as soon and as often as required and be made available to an Inspector at the mine site at all times. The Permittee must submit updated versions of the OWTP OMS to the Chief Inspector.

(ii) The Permittee must ensure no substantive changes are made to the operations phase water treatment processes without the approval of the Chief Inspector.

(b) Monitoring and Reporting

(i) The Permittee must monitor, track and report in the Annual Reclamation Report on the performance of the Water Treatment Facility. The Permittee must report information on system performance, volume and quality of contact water influent and effluent of the water treatment system, volumes of reagents used, volumes and characteristics of waste generated, and information on any process changes.

(ii) The Permittee must ensure the Annual Reclamation Report includes a breakdown of all annual costs associated with operation of the Operations Water Treatment Facility, including labour, electricity, waste handling and storage and all delivered costs for diesel, reagents, etc.

7. Sediment and Erosion Control

(a) The Permittee must ensure that the Erosion and Sediment Control Management Plan is implemented. This plan must be reviewed at least annually and updated to reflect results of effectiveness monitoring and potential contingency requirements, changing site conditions, and site-specific freshet-related considerations. The Permittee must ensure substantive changes are provided to the Chief Inspector prior to implementation, and annual updates are reported in the Annual Reclamation Report.

(b) The Permittee must ensure that erosion and sediment control prescriptions, and associated effectiveness monitoring programs, are developed based on site-specific assessments of risk and consequence prior to construction of individual mine and water management components.

(c) The Permittee must ensure that unauthorized release of sediment-laden water released from the authorized water management system must be characterized and reported to the Chief Inspector, with recommendations for improvement to the water management system if required.

(d) The Permittee must initiate progressive reclamation where practicable to control erosion around the mine area.

8. Soil Salvage and Storage

(a) The Permittee must salvage and stockpile topsoil, overburden, and organic material to the greatest extent possible for use in reclamation.

(b) The Permittee must ensure a Qualified Professional monitor and direct sampling, soil salvage, stockpiling activities on-site.

(c) The Permittee must ensure an inventory of salvaged and stockpiled soil, including the locations, origins, and quantities of material, is documented and reported in the Annual Reclamation Report.

(d) The Permittee must protect stockpiles from erosion, degradation, and contamination using appropriate best management practices, and monitor them as appropriate to ensure effective controls are maintained. The Permittee must ensure stockpile protection activities and monitoring results are documented and reported in the Annual Reclamation Report.

(e) The Permittee must ensure soil stockpiles are located in areas that minimize handling requirements during site preparation and mine operations, provide adequate accessibility for reclamation activities, and optimize sediment control options.

(f) The Permittee must ensure soil stockpiles are clearly marked to ensure that they are protected during construction and mine operations.

(g) The Permittee must ensure stockpiled soil suitable for use in reclamation is not used as fill.

9. Vegetation Management

(a) The Permittee must ensure that the Vegetation Management Plan is implemented.

(b) The Permittee must limit disturbance to vegetation to those areas approved by this permit (Figure 1a and Figure 1b) and ensure that disturbance limits are clearly communicated and adhered to on-site. Where only minimal vegetation removal is proposed, the Permittee must ensure efforts are made to limit ground disturbance to minimize soil erosion and maximize the regeneration potential of the site.

(c) The Permittee must ensure that the Invasive Plants Management Plan, dated July 2015 is implemented.

(d) The Permittee must prevent the establishment of invasive plants on-site, manage and control weeds that do establish on the site, and take reasonable efforts to ensure that weeds do not move from the site to adjacent areas. The Permittee must ensure that seed used on-site is certified weed free and consider using non-toxic means for weed control.

(e) The Permittee must salvage and stockpile woody debris, including stumps, roots, limbs and rotting logs, that is generated during clearing and grubbing operations. The Permittee must keep an inventory of salvaged and stockpiled woody debris, including the locations, origins, and quantities of material, and report in the Annual Reclamation Report.

(f) The Permittee must avoid chipping or burning of woody debris suitable for use in reclamation.

10. Wildlife Protection

(a) The Permittee will implement the Wildlife Management Plan (REF 1.10), to prevent and mitigate impacts to wildlife, with the monitoring results provided in the Annual Reclamation Report.

(b) The Permittee must ensure that strategies, designed by a Qualified Professional with suitable experience, to prevent human-wildlife interactions are included in the Waste Management Plan and implemented.

(c) The Permittee must ensure that where exclusion fencing is installed that it is maintained in effective working order at all times that people are present on site.

(d) The Permittee must conduct monitoring and/or track incidental observations of bats in the underground throughout mine life. If bats are observed to be present the Permittee must:

(i) Develop, and submit to the Chief Inspector within 3 months of bat observations, an operational management plan to minimize risk to bats, particularly with respect to direct mortality and spread of white nose syndrome and

(ii) Conduct a bat survey and take all reasonable efforts to move bats out of the underground, prior to securing the underground openings.

(e) The Permittee must avoid wildlife sensitive periods and/or adhere to timing windows for construction activities. Where this is not practicable, the Permittee must adhere to mitigation measures outlined in the Wildlife Management Plan.

(f) Pursuant to Part 1.6.9 of the Code, the Mine Manager must incorporate in the mine safety program a no hunting and shooting policy, for the mine permit area (Figure 1a and Figure 1b).

(g) The Permittee must implement a policy of no fishing and hunting for all employees and contractors while on company business or while commuting to and from the mine on the Brucejack Access Road west of Highway 37.

11. Archaeological Resources

If archaeological materials or cultural features are encountered during construction or related activities, the Permittee must implement procedures as set out in the Heritage Management Plan.

12. Ongoing Reclamation Research

(a) The Permittee must by July 31, 2020, submit to the Chief Inspector a Reclamation Research Program that includes details for achieving the research requirements outlined in this permit with a schedule for implementation and description for how results will be utilized and reported.

(b) The Permittee must ensure a summary of all research being conducted under this section is provided in the Annual Reclamation Report and a detailed summary of results is provided in the Five Year Mine Plan and Reclamation Program updates.

(c) The Permittee must ensure research is conducted to explore opportunities for enhancement of both habitat and surface drainage control on the Mine Site, particularly with respect to design of the surface topography predicted to remain once infrastructure is decommissioned at closure. The scope of this research must include evaluation of options to optimize remaining concrete foundations.

(d) The Permittee must ensure research is conducted to evaluate opportunities for amending soil that is to be used for reclamation purposes to enhance the soil suitability, if necessary, based on soil analyses.

(e) The Permittee must ensure testwork is conducted to determine soil replacement depths and locations required to achieve the designed surface topography and end land use objectives.

(f) The Permittee must ensure research is conducted to determine the viability of revegetation with native plant species, including culturally important species.

(g) The Permittee must ensure research is conducted to assess decompaction methodologies to ensure that the severity of compaction that exists prior to commencing reclamation activities is effectively addressed in a manner intended to achieve end land use objectives and erosion control. The scope of this research must include mine access roads and mine site pads.

(h) The Permittee must develop a reclamation success monitoring program designed to evaluate the success of revegetation, landscape design, and erosion control that specifies sampling parameters and performance criteria.

(i) The Permittee must develop a monitoring program for evaluating metal uptake in exposed terrestrial and aquatic ecosystems, which specifies sampling requirements and performance criteria and targets areas where potential pathways for metal uptake via (e.g., dust, growth medium, or contact water). Where harmful levels are found, the Permittee must take any corrective action necessary to mitigate to ensure levels are safe for plant and animal life.

13. Subsidence Monitoring

The Permittee must develop a Subsidence Monitoring and Management Plan and submit it to the Chief Inspector as part of the 5 Year Mine Plan and Reclamation Program update. The plan must be designed to evaluate the effectiveness of subsidence controls, provide early warning of surface expression that may result in changes to terrestrial or aquatic values and include an adaptive management approach to ensure that appropriate mitigation and/or closure plans are developed as needed.

E. Reclamation and Closure Program

1. Reclamation Security

(a) The Permittee must maintain a total security for this permit of Thirty One Million Seven Hundred Thousand ($31,700,000.00) dollars. The security will be held by the Minister of Finance for the proper performance of the approved program and all the conditions of this permit in a manner satisfactory to the Chief Inspector.

(b) Notwithstanding the security posted as a condition of this Permit, the Permittee remains responsible for covering all closure and reclamation costs associated with reclamation and environmental protection.

2. Annual Reclamation Report

By March 31 of each year, starting in 2016, the Permittee must submit an Annual Reclamation Report in a form containing the information required by the Chief Inspector.

3. Land Use

The Permittee must reclaim the land with the intent of re-establishing average pre-mining capability to the following end land use objective: wildlife habitat, particularly matrix habitat for mountain goat, grizzly bear and hoary marmot on the mine site and high elevation sections of the Transmission Line, and moose and grizzly bear habitat at lower elevations of the Transmission Line. Achieving land capability objectives and habitat enhancement must guide the reclamation program.

4. Revegetation

(a) The Permittee must, where vegetation is a necessary component of fulfilling the approved end land use objective, ensure the land is revegetated to a self-sustaining state using appropriate and or native plant species including culturally important native species.

(b) The Permittee must ensure revegetation programs are designed to restore wildlife habitat where practicable.

(c) The Permittee must ensure revegetation practices are conducted to provide appropriate species and densities that are similar to naturally occurring ecosites at similar elevations, aspects, and climatic conditions.

(d) The Permittee must develop details of the proposed revegetation programs, including species and densities prescribed for specific areas, based on input from the reclamation research program required as a condition of this permit.

5. Growth Medium

(a) Where replacement of salvaged soil will occur, the Permittee must ensure surface preparation is done in a manner that controls erosion and achieves end land use objectives.

(b) The Permittee must monitor soil replacement to ensure the minimum depths are achieved and a confirmation sampling plan must be implemented to ensure quality of soil used for reclamation purposes will achieve end land use objectives. The Permittee must present the results in the Annual Reclamation Report.

(c) With the exception of areas where closure plans require compaction prior to placement of growth medium in order to reduce infiltration and contact water, the Permittee must ensure all areas are reclaimed and decompacted to the minimum depth required to adequately address the severity of compaction prior to placement of soil and or vegetation, in a manner intended to achieve end land use objectives and erosion control.

6. Contaminated Sites Assessment

The Permittee must develop and implement risk-based monitoring programs designed to ensure all potential sources of contamination have been addressed in order to satisfy reclamation success objectives and water quality requirements.

7. Erosion Control

The Permittee must ensure that long term erosion potential is minimized through landform configuration, appropriate surface preparation, development of maintenance-free vegetation covers, where applicable, and self-sustaining drainage control features and watercourses.

8. Surface Water Management Ponds and Channels

(a) The Permittee must ensure all surface water management ponds and water diversions are reclaimed to satisfy stability and erosion control requirements and the approved end land use once no longer required.

(b) At least 3 months prior to decommissioning water treatment facilities, the Permittee must develop and submit to the Chief Inspector for approval, a Closure Plan that addresses all non-contact and contact water management features that will no longer be required.

9. Transmission Line

At least 3 months prior to decommissioning the Transmission Line, the Permittee must develop and submit to the Chief Inspector for approval, a Reclamation and Closure Plan to satisfy the approved end land use objectives.

10. Borrows and Quarries

The Permittee must ensure borrow pits and quarries are reclaimed to satisfy stability and erosion control requirements and the approved end land use, once no longer required.

11. Mine Roads

(a) The Permittee must ensure all mine roads are reclaimed, in accordance with recommendations of a Qualified Professional, to satisfy the approved end land use objectives, including all reasonable effort to fully re-configure to conform to adjacent landscape where long-term stability is not compromised, unless permanent access is required.

(b) Individual mine roads may be exempted from the requirement for total reclamation pursuant to this permit if either:

(i) the Permittee can demonstrate that an agency of the Crown has explicitly accepted responsibility for the operation, maintenance and ultimate deactivation and abandonment of the road or

(ii) the Permittee can demonstrate that another private party has explicitly agreed to accept responsibility for the operation, maintenance and ultimate deactivation and abandonment of the road and has, in this regard, agreed to comply with all the terms and conditions, including bonding provisions, of this reclamation permit, and to comply with all other relevant provincial government (and federal government) regulatory requirements.

(c) The Permittee must ensure all access roads are effectively blocked to prevent inadvertent vehicular access to surface areas of the mine that may be dangerous.

12. Structures and Equipment

Prior to abandonment, the Permittee must, unless the Chief Inspector has made a ruling with respect to heritage project status or industrial use:

(a) Remove all machinery, equipment and building superstructures, unless the Permittee can demonstrate that another private party has explicitly agreed to accept responsibility for its operation and maintenance;

(b) Remove all synthetic sediment control structures, such as turbidity curtains, ditch liners, and soil covers not required after closure and where practical ,disposed of in the underground prior to flooding or buried in place where sufficient cover materials exist;

(c) Remove all concrete foundations, or covered with sufficient growth medium and re-vegetated, or otherwise reclaimed to fulfill approved end land use objectives based on input from the reclamation research program required as a condition of this permit; and

(d) Remove all scrap material and dispose of in an approved facility.

13. Temporary Shutdown

(a) If the mine ceases production, including for seasonal closure, within one month the Permittee must submit a Care and Maintenance Plan which describes, documents, and tracks key aspects of the ongoing mitigation, monitoring, and maintenance requirements for the care and maintenance of the site. The Permittee must ensure the manual documents the outstanding reclamation activities and closure requirements for the site, and develop a trigger action response plan that will be implemented to activate closure activities based on monitoring results and site conditions. This document must be a living document with updates submitted to the Chief Inspector whenever material changes occur.

14. Mine Plan and Reclamation Program Update

On or before July 31, 2020, and every 5 years thereafter, the Permittee must submit an updated Mine Plan and Reclamation Program, providing, but not limited to, the following:

(a) The current status of the mine plan and reclamation obligations;
(b) A compilation and interpretation of all monitoring including ML/ARD prediction, water quality and quantity, and post-closure groundwater elevation prediction updates;
(c) Closure and maintenance activities;
(d) Any changes to the reclamation program that affect long-term mitigation;

(e) Reclamation research program;
(f) Contingency plans;
(g) Schedule for completion of reclamation works and
(h) A breakdown of outstanding liabilities and associated costs.

15. Closure Plan

(a) Twelve months prior to final closure, the Permittee must submit a Closure Plan providing, but not limited to, the following:

(i) Closure objectives and criteria for each mine component;
(ii) Provide the current status of the mine plan and reclamation obligations;
(iii) A compilation and interpretation of all monitoring including ML/ARD prediction, water quality and quantity;
(iv) Closure and maintenance activities;
(v) Any changes to the reclamation program that affect long-term mitigation;
(vi) Reclamation research program;
(vii) Contingency plans;
(viii) Schedule for completion of reclamation works and
(ix) A breakdown of outstanding liabilities and associated costs.

(b) Concurrent with the final Closure Plan, the Permittee must submit a Closure Management Manual which describes and documents key aspects of the operational surveillance and monitoring requirements used to track important changes that could affect long-term mitigation performance, monitoring and maintenance requirements. This document must be a living document with updates submitted to the Chief Inspector, at least every five years while the permit remains active, and when material changes occur.

PO BOX 49334 1055 Dunsmuir Street
Vancouver, BC V7X1L4

Dear Permittee:

Enclosed is Amended Permit 107835 issued under the provisions of the *Environmental Management Act*. Your attention is respectfully directed to the terms and conditions outlined in the permit. An annual fee will be determined according to the Permit Fees Regulation.

This permit does not authorize entry upon, crossing over, or use for any purpose of private or Crown lands or works, unless and except as authorized by the owner of such lands or works. The responsibility for obtaining such authority rests with the permittee. This permit is issued pursuant to the provisions of the *Environmental Management Act* to ensure compliance with Section 120(3) of that statute, which makes it an offence to discharge waste, from a prescribed industry or activity, without proper authorization. It is also the responsibility of the permittee to ensure that all activities conducted under this authorization are carried out with regard to the rights of third parties, and comply with other applicable legislation that may be in force.

When a spill or the risk of a spill occurs, the responsible person (spiller) must report it immediately by calling 1-800-663-3456 in accordance with the Spill Reporting Regulation. More information is available at:
https://www2.gov.bc.ca/gov/content?id=1EAB9109A9E9407EA646050A9D431C41

Pursuant to Section 16 of the *Environmental Management Act*, the director has amended authorization 107835.

This decision may be appealed to the Environmental Appeal Board in accordance with Part 8 of the *Environmental Management Act*. An appeal must be delivered within 30 days from the date that notice of this decision is given. For further information, please contact the Environmental Appeal Board at (250) 387-3464.

Administration of this permit will be carried out by staff from the Environmental Protection Division's Regional Operations Branch. Plans, data and reports pertinent to

the permit are to be submitted by email or electronic transfer to the Director, designated Officer, or as further instructed.

Please be reminded that the director may, for the protection of the environment in accordance with Section 16 of the *Environmental Management Act*, require the permittee to do one or more of the following at any time:

- repair, alter, remove, improve or add to existing works, or construct new works, and submit plans and specifications for works specified in this authorization.
- conduct monitoring, and may specify procedures for monitoring and analysis, and procedures or requirements respecting the handling, treatment, transportation, discharge or storage of waste.
- provide security in the amount and form, and subject to the conditions, specified by the director.
- conduct studies and report information in accordance with the specifications of the director.
- recycle certain wastes and recover certain reusable resources, including energy potential from wastes, in accordance with the specifications of the director.
- submit copies of reports and notifications to specified Indigenous Groups, within specified timelines, in accordance with the specifications of the director.

For more information about how the Ministry will assess compliance with your permit please refer to gov.bc.ca/environmentalcompliance.

For more information about how to make changes to your permit and to access waste discharge amendment forms and guidance, please refer to gov.bc.ca/wastedischarge-authorizations.

Yours truly,

Neil Bailey, P. Eng.
for Director, *Environmental Management Act*
Authorizations - North Region

MINISTRY OF ENVIRONMENT AND CLIMATE CHANGE STRATEGY

PERMIT

107835

Under the Provisions of the Environmental Management Act

Pretium Resources Inc.

Suite 2300, Four Bentall Centre
PO BOX 49334 1055 Dunsmuir Street
Vancouver, BC V7X1L4

is authorized to discharge mine related contaminants and effluent to Brucejack Lake and Brucejack Creek, from the Brucejack Mine located approximately 60 km North of Stewart, British Columbia, subject to the requirements listed below.

Contravention of any of these requirements is a violation of the Environmental Management Act and may lead to prosecution.

This authorization supersedes and replaces all previous versions of Permit 107835 issued under Section 14 of the *Environmental Management Act*.

Where this authorization provides that the director may require an action to be carried out, the permittee must carry out the action in accordance with the requirements of the director.

1. AUTHORIZED DISCHARGES

1.1 Brucejack Lake Final Discharge Point

The permittee must manage the operations and authorized discharges in sections 1.2, 1.3, 1.4, and 1.5, such that water quality at the outlet of Brucejack Lake (monitoring site BJ 3.10) does not exceed the maximum concentrations specified in section 1.1.1. The site reference number and final point of compliance for this discharge is E298312.

Date issued: August 31, 2015
Date amended: August 21, 2023
(most recent)

Neil Bailey, P. Eng.
for Director, *Environmental Management Act*
Authorizations - North Region
Permit Number: 107835

1.1.1 The characteristics of the Brucejack Lake Outlet (BJ3.10) water quality must not exceed the following:

Parameter	Maximum (1)	Units
48 hr Daphnia magna single concentration toxicity test	50% Survival in 100% Concentration, Minimum (2)	Not applicable
Algal Growth Inhibition Test (EPS 1/RM/25)	Growth Inhibition must be less than 25% for 100% Lake Outlet Water (2)	Not applicable
Total Suspended Solids	30 (maximum) 15 (monthly average)	mg/L mg/L
pH	6.5- 8.5	
Nitrite	240	µg/L as N
Nitrate	11.5	mg/L as N
Ammonia	4.0	mg/L as N
Total Antimony	28	µg/L
Total Arsenic	10	µg/L
Total Iron	1.7	mg/L
Total Silver	0.46	µg/L

(1) Maximum allowable concentration in any grab sample.
(2) Refer to section 4.3.

1.1.2 The annual average authorized discharge rate from Brucejack Lake is 50,000 m^3/day. The average authorized discharge volume has been set to enable the calculation of discharge fees as required by the Permit and Approval Fees and Charges Regulation.

1.1.3 The discharge is authorized from Authorized Works, which are various discharge lines and outfalls from treatment works, collection works, ditches, oil/water separator, pipes, sumps, pumps, flow

monitoring and water sampling devices, a low-level weir, and Brucejack Lake.

1.1.4 The location of the facilities from which the discharge is authorized to originate and the point where the discharge is authorized to occur is Mining Lease 1038598. The Authorized Works and various points of discharge are as shown in attached Site Plan A.

1.2 Water Treatment Plant and Contact Water Pond Effluent

This section applies to the discharge of effluent from the Water Treatment Plant (WTP) and the Contact Water Pond (CWP) to Brucejack Lake and/or for use as process water within the mill building. The site reference number for the WTP discharge is E302957. The site reference number for the CWP direct discharge is E306114.

1.2.1 The maximum authorized rate of discharge from the WTP to Brucejack Lake is 10,000 m^3/day.

1.2.2 The maximum authorized rate of discharge from the CWP to Brucejack Lake is indeterminate.

1.2.3 Subject to subsection 1.2.4, the characteristics of the WTP and CWP discharge to Brucejack Lake must not exceed the following:

Parameter	CWP Maximum (1)	WTP Maximum (1)	Units
Total Suspended Solids (TSS)	25 (2) 150 NTU (3)	25	mg/L
pH	6.5 – 8.5	6.5 – 8.5	pH
Total Aluminum	0.3	0.3	mg/L
Total Arsenic	10	10	µg/L
Total Cadmium	0.25	0.25	µg/L
Total Cobalt	10	10	µg/L
Total Chromium (see section 3.4)	20	20	µg/L
Total Copper	10	10	µg/l
Total Iron	1.0	1.0	mg/L
Total Lead	5	5	µg/L
Total Manganese	22	22	mg/L
Total Silver	0.1	0.1	µg/L
Total Zinc	20	20	µg/L

(1) Concentration in any grab sample that triggers requirements in section 1.2.4
(2) When available CWP storage capacity is between 10,000 and 50,000 m^3
(3) When available CWP storage capacity is less than 10,000 m^3.

1.2.4 Should the concentrations in section 1.2.3 be exceeded for the WTP or CWP discharge to Brucejack Lake, the permittee must immediately upon receipt of analytical results recirculate effluent through the CWP and WTP until treated water quality does not exceed the discharge characteristics specified in section 1.2.3.

Date issued: August 31, 2015
Date amended: August 21, 2023
(most recent)

Neil Bailey, P. Eng.
for Director, *Environmental Management Act*
Authorizations - North Region
Permit Number: 107835

1.2.5 **Water Treatment Plant Authorized Works**

The discharge is authorized from Authorized Works, which are Brucejack Lake, and the WTP that utilizes pH adjustment for metals precipitation using hydrated lime and, if necessary, sodium sulphide; coagulation using ferric sulphate; and flocculation using anionic polymer and microsand for removal of TSS; clarification using lamella plates and disc filter; sludge dewatering using centrifuge and cationic polymer; and pH neutralization using sulfuric acid and calcium hydroxide.

1.2.6 **Contact Water Pond Authorized Works**

The discharge is authorized from Authorized Works, which are Brucejack Lake and a CWP with a minimum storage capacity of 50,000 m^3. Related appurtenances include a permanent emergency spillway for events exceeding the design capacity as well as a drawdown pump and pipeline system to a deep lake outfall.

1.2.7 The location of the WTP and the deep lake discharge line are as shown on Site Plan B. The sources of the WTP influent are mine water, process water and the CWP.

1.2.8 The location of the CWP and the direct discharge line are as shown on Site Plan B. The sources of the CWP influent are various surface water collection works surrounding the mine site, Diesel Power Station (DPS) pond effluent, WTP effluent, as well as emergency storage of untreated Mine Water.

1.3 **Thickened Tailings Slurry**

This section applies to the discharge of Thickened Tailings Slurry via the tailings discharge lines to Brucejack Lake. The site reference number for this discharge is E302910.

1.3.1 The annual average authorized rate of discharge is 3,800 tonnes per day.

1.3.2 The tailings outfall must never be positioned more than 7.5 m above the lake bottom (i.e., the top of the natural lake bottom or deposited tailings, whichever is higher) unless approved by the director.

1.3.3 The discharge is authorized from Authorized Works, which are Brucejack Lake, tailings discharge lines to Brucejack Lake, and thickening processes and related appurtenances approximately located as shown on Site Plan B.

1.4 Water Treatment Plant Sludge

This section applies to co-deposition of the WTP Sludge with tailings via the tailings discharge lines to Brucejack Lake. The site reference number for this discharge is E302910.

1.4.1 The maximum rate of sludge deposition is indeterminate.

1.4.2 The mixing ratio of WTP Sludge to tailings must not exceed 2% sludge by dry weight.

1.4.3 The discharge is authorized from Authorized Works, which are Brucejack Lake, tailings discharge lines to Brucejack Lake, tailings thickening processes and related appurtenances approximately located as shown on Site Plan B.

1.5 Treated Domestic Wastewater

This section applies to the discharge of Treated Domestic Wastewater from the mine operations and camp infrastructure to Brucejack Lake. The site reference number for this discharge is E302911.

1.5.1 The maximum authorized rate of discharge is 175 m^3/day, 365 days/year.

1.5.2 The characteristics of the treated effluent must not exceed:

(a) 45 mg/L for Total Suspended Solids, and

(b) 45 mg/L for 5-day Biological Oxygen Demand.

1.5.3 The discharge is authorized from Authorized Works, which are Brucejack Lake and three Filterboxx C75 treatment units, or an equivalent unit(s) approved by the director, and related appurtenances including a deep lake outfall.

1.5.4 The location of the Domestic Wastewater Treatment plant and the deep lake outfall discharge line are as shown on Site Plans A and B.

2. GENERAL CONDITIONS

2.1 Maintenance of Works and Emergency Procedures

2.1.1 The permittee must regularly inspect the Authorized Works and maintain them in good working order. If components of the Authorized Works have a manufacturer's recommended schedule, then those components must, at a minimum, be maintained in accordance with that schedule.

2.1.2 The permittee must maintain a record of inspections and maintenance of the Authorized Works and make the record available to an officer upon request.

2.1.3 In the event of an emergency or other condition which prevents normal operation of the Authorized Works or leads to an unauthorized discharge, the permittee must take remedial action immediately to restore the normal operation of the Authorized Works and to prevent any unauthorized discharges. The permittee must immediately report the emergency or other condition and the remedial action that has and will be taken to the EnvironmentalCompliance@gov.bc.ca email address or as otherwise instructed by the director.

2.1.4 The director may require the permittee to reduce or suspend operations until the Authorized Works have been restored, and/or corrective steps have been taken to prevent unauthorized discharges.

2.2 Construction of Water Management and pollution Control Works

2.2.1 The permittee must ensure the plans and specifications for the various phases of the WTP, the Domestic Wastewater Treatment Plant and other associated works authorized under sections 1.2, 1.3, 1.4, and 1.5 are certified by a Qualified Professional and retained on site for inspection prior to the commencing any of the discharges from either sources.

2.2.2 The permittee must cause the Qualified Professional to certify that the works have been constructed in accordance with such plans and specifications before discharge commences under this authorization, and a maximum of 45 days following completion of construction.

2.3 Controlled Bypasses

The permittee must not allow any discharge authorized by this authorization to bypass the Authorized Works, except with the prior written approval of the director.

2.4 Temporary Shutdown

In the event of a temporary shutdown in construction and mining activities at the site, the permittee must notify the director in writing and must ensure all permit conditions continue to be met.

2.5 Publication of Documents

The Ministry of Environment and Climate Change Strategy publishes Regulatory Documents on its website for the purpose of research, public education and to provide transparency in the administration of environmental laws. The permittee acknowledges that the Province may publish any Regulatory Documents submitted by the permittee, excluding information that would be exempted from disclosure if the document was disclosed pursuant to a request under section 5 of the Freedom of Information and Protection of Privacy Act, and the permittee consents to such publication by the Province.

3. OPERATIONAL REQUIREMENTS

3.1 Turbidity Curtains

The Waste Rock and Tailings disposal must not proceed unless a minimum of three turbidity curtains are in place across the lake outlet approximately as shown on Site Plan B.

3.2 Source Control of Nitrite and Nitrogen

3.2.1 The permittee must maintain an up-to-date version of the Nitrogen Management Plan (NMP) on site for inspection by Environmental Protection staff.

3.2.2 The permittee must implement the most current version of the NMP. The NMP describes source control measures, monitoring, auditing and reporting activities that are undertaken to ensure nitrogen sources are controlled and minimized, and that the discharge standards in section 1.1 are met.

3.2.3 The permittee must maintain records of the activities described in the NMP available for inspection at the request of Environmental Protection staff.

3.3 **Closure Underground Water Quality Adaptive Management Plan**

3.3.1 The permittee must develop a post closure management plan with the intent of limiting all impacts within Brucejack Creek to levels acceptable to the director.

3.3.2 The Plan must assess all available management options including but not limited to:

(a) directing mine pool water on closure to the CWP to allow for attenuation there,

(b) continuing to use the WTP and/or discharging the water where it would have minimal impact.

(c) In addition, the plan must include appropriate monitoring, water quality triggers, and management actions to maintain water quality throughout closure and post closure.

3.3.3 The Plan must include all available and updated hydrology, hydrogeology and geochemistry results and propose further work necessary to better define closure and post closure Water Quantity and Quality predictions.

3.3.4 An initial Plan submission is due by July 31, 2020. Subsequent updates with respect to ongoing findings and management options are required every five (5) years or as requested by the director. The final report must be submitted 2 years prior to closure for the approval of the director.

3.4 **Chromium Management Plan**

3.4.1 The permittee must maintain an up-to-date Chromium Management Plan (CMP) on site for inspection by Environmental Protection staff.

3.4.2 The permittee must implement the most current version of the CMP to manage, monitor and mitigate the release of hexavalent chromium from cement in the underground workings, and ensure that the BC Water Quality guidelines for Cr(III) and Cr(VI) are not exceeded at Brucejack Lake outlet (BJ 3.10).

3.4.3 The permittee shall implement the monitoring program and mitigations described in the most current version of the CMP if either of the following occurs:

(a) dissolved Chromium levels prior to treatment in the WTP exceed the trigger level of 10 µg/L,

(b) dissolved Chromium levels at BJ 3.10 exceed 1 µg/L.

3.5 Outfall Inspection

3.5.1 The permittee must cause the outfall(s) and discharge lines to be inspected once every year by a Qualified Professional or certified tradesperson to ensure they and all associated piping are in good working condition, there are no leaks, no major bends which would erode due to the flow of the tailings slurry, and the height of tailings discharge is in compliance with section 1.1.3 of this permit.

3.5.2 Inspections may include a combination of the following: bathymetric surveys, camera inspections, visual inspections, digital sonar surveys, etc.

3.5.3 The permittee must submit an inspection report as part of each annual report unless concerns are noted. In the latter instances, the permittee must submit an inspection report accompanied by a mitigation plan to the director with 45 days after the inspection date.

3.6 Water Treatment Plant Sludge

3.6.1 The permittee must implement the WTP sludge monitoring and management program outlined in the most current version of the Metal Leaching and Acid Rock Drainage (ML/ARD) Management Plan.

3.6.2 Co-subaqueous deposition of WTP Sludge in Brucejack Lake with tailings is permitted as described in section 1.4.

3.6.3 On-site sub-aerial storage of the WTP Sludge must not exceed twelve (12) months, unless approved by the director.

3.6.4 Disposal of the WTP Sludge does not require approval if it is disposed off- site at a licensed facility.

3.7 **Reagents**

3.7.1 The permittee must maintain records of reagent types, volumes and usage rates for various water treatment and ore concentration process.

3.7.2 When commissioning any specific process and or adding/changing reagent(s) the permittee must compile and submit documentation to the director 15 days prior to their usage.

3.8 **Diesel Power Station (DPS) Oil/Water Separator**

3.8.1 The permittee must develop and implement a preventative maintenance, monitoring, and inspection program for the DPS separator system and DPS pond by January 31, 2019.

3.8.2 The permittee must maintain records of inspections, cleanouts, accidental discharges, and a site plan, available for inspection at the request of Environmental Protection staff.

4. **MONITORING REQUIREMENTS**

Locations of all monitoring sites are depicted in Site Plans C and D. Appendices A and B specify the monitoring periods and frequencies, and monitoring parameters for the surface water and groundwater monitoring sites.

The groundwater monitoring frequencies will be as per Appendix B unless the permittee documents specific safety conditions present at a given well, or other condition such as lack of recovery, frozen or dry wells, that justify missing a specific sampling event. The director may approve revisions to the Groundwater Monitoring Program subject to the permittee submitting a review and recommendations by a Qualified Professional.

4.1 **Benthic Invertebrates**

4.1.1 The permittee must implement the benthic invertebrate program as specified in Appendix A using personnel or Qualified Professionals trained in the Environment Canada CABIN protocol.

4.1.2 The benthic invertebrate monitoring frequencies at BJ 2.62 and BJ 1.74 will be annually, as per Appendix A, for 3 years (i.e., 2019, 2020 and 2021) after which time the permittee may request a reduction of the monitoring frequency to once every 3 years.

4.2 **Sediment Sampling**

4.2.1 The permittee must implement the sediment program as specified in Appendix A using personnel or Qualified Professionals trained in the procedures.

4.2.2 The Program must analyze biologically relevant fine sediments less the 63 µm in size.

4.3 **Toxicity Sampling Requirements for the Outlet of Brucejack Lake (BJ 3.10)**

4.3.1 As per section 1.1, the discharge at the outlet of Brucejack Lake must not be acutely toxic to aquatic organisms or inhibit algal growth. The required test methods are:

(a) Acute/ Lethal Toxicity - 48 hr Daphnia magna single concentration toxicity test (EPS 1/RM/14 2nd edition, December 2000), and

(b) Growth Inhibition Test Using a Freshwater Alga (EPS 1/RM/25).

4.3.2 A lethal toxicity test failure is defined as undiluted effluent that results in >50% mortality of Daphnia magna in 48 hours.

4.3.3 A Growth Inhibition test failure is defined as whenever the growth inhibition in 100% lake outlet effluent is determined to be greater than 25%.

4.3.4 In the event of failures, the Ministry must be notified (as per section 5.3 "Non-compliance Notification) and the specific test must be immediately repeated.

4.3.5 For acute toxicity, the follow-up test must use multiple concentrations to determine the 48 hr LC50 for Daphnia magna.

4.3.6 Test results must be validated, and results must be reported as described in approved Environment Canada biological test methods as referred to above.

4.4 **Long Term Trend Analysis Toxicity Sampling**

4.4.1 A test for survival and growth using larvae of freshwater midges (Chironomus dilutus) (water only) (test method EPS1/RM/32) must

be conducted on 100% lake outlet effluent. Results must be included in the Annual Report.

4.4.2 Trends in survival and growth must be plotted, including all available data from previous tests.

4.4.3 The summary must include a description of the results in the context of ecological effects in the receiving environment.

4.5 Aquatic Effects Monitoring Program (AEMP)

4.5.1 The permittee must implement the most current version of the AEMP, approved by the director.

4.5.2 The permittee must submit results of the AEMP, prepared by a Qualified Professional, to the director by March 31st of the year after the studies are conducted in accordance with section 5.5. Based on the results of this monitoring program, the monitoring requirements may be extended or altered by the director.

4.5.3 Changes to the AEMP must be approved by the director in writing regardless of any language in the approved program indicating otherwise.

4.5.4 Recommendations for changes to the monitoring program must be prepared by a Qualified Professional and submitted to the director.

4.6 Sampling and Analytical Procedures

4.6.1 The permittee must carry out sampling in accordance with the procedures described in the "British Columbia Field Sampling Manual for Continuous Monitoring and the Collection of Air, Air-Emission, Water, Wastewater, Soil, Sediment, and Biological Samples, 2013 Edition" or most recent edition, or by alternative procedures as authorized by the director.

A copy of the above manual is available on the Ministry web page at https://www2.gov.bc.ca/gov/content/environment/research-monitoring-reporting/monitoring/laboratory-standards-quality-assurance/bc-field-sampling-manual.

4.6.2 The permittee must carry out analyses in accordance with procedures described in the "British Columbia Environmental Laboratory Manual (2015 Permittee Edition)", or the most recent edition, or by alternative procedures as authorized by the director.

A copy of the above manual is available on the Ministry web page at: https://www2.gov.bc.ca/gov/content/environment/research-monitoring-reporting/monitoring/laboratory-standards-quality-assurance/bc-environmental-laboratory-manual

4.7 Quality Assurance Quality Control (QA/QC)

4.7.1 The permittee must obtain from the analytical laboratory(ies) their precision, accuracy and blank data for each sample set submitted by the permittee and an evaluation of the data acceptability, based on criteria set by such laboratory.

4.7.2 The permittee must submit samples to analytical laboratory(ies) that meet the definition of a qualified laboratory under the Environmental Data Quality Assurance Regulation.

4.8 Exceedance of Guidelines at BJ 3.10

4.8.1 In the event that water quality parameters measured at BJ 3.10 exceed their respective "British Columbia Water Quality Guidelines" or discharge standards in section 1.1, the director may require the following:

(a) Additional sampling and monitoring;

(b) Risk assessment that incorporates the loadings and concentrations considering biological sensitivity of the area;

(c) Submission of an **Environmental Management Plan** in accordance with the following section for each parameter of concern; and

(d) Submission of any other information the director considers necessary to assess environmental impact or to protect the environment.

4.8.2 An **Environmental Management Plan** must be to the satisfaction of the director and include but not be limited to:

(a) Remedial and mitigation measures for the parameters(s) of concern;

(b) An attainment schedule, whereby the permittee must specify actions and interim targets with associated timelines for reducing the amount of contaminants discharged into the

environment, with the goal of attainment of water quality guidelines or other criteria as specified by the director;

(c) Revised modelling predictions for the parameter of concern based on monitoring data and refinements to source term information; and,

(d) Periodic review of the activities to date, and the implementation of future strategies as required by the director. The review will include but not be limited to performance and progress report on control and reduction programs and also provide an opportunity for adjustments to the monitoring program in light of new scientific knowledge and other related technical advances.

5. REPORTING REQUIREMENTS

5.1 Spill Reporting

The permittee must immediately report all spills to the environment (as defined in the Spill Reporting Regulation) in accordance with the Spill Reporting Regulation. Notification must be via the Provincial Emergency Program at 1-800-663-3456.

5.2 Reporting of Monitoring Results

The permittee must submit field and laboratory monitoring results, including a summary of non-compliances and corrective actions taken, by email to the Ministry at EnvAuthorizationsReporting@gov.bc.ca within 30 days of the end of the month in which the monitoring occurred. The permittee must submit such data and information in a form that is tabulated, graphically represented, and interpreted to the satisfaction of the director.

For guidelines on how to properly name the files and email subject lines or for more information visit the Ministry website:

https://www2.gov.bc.ca/gov/content/environment/waste-management/waste-discharge-authorization/comply#submitroutinereport

5.3 Non-Compliance Notification

5.3.1 The permittee must immediately notify the director or designate by email at EnvironmentalCompliance@gov.bc.ca, or as otherwise instructed by the director of any non-compliance with the

requirements of this authorization by the permittee and take remedial action to remedy any effects of such non- compliance.

5.3.2 The permittee must provide the director with written confirmation of all such non-compliance events, including available test results within 24 hours of the original notification unless otherwise instructed by the director.

5.3.3 Non-compliance notification must also be provided to the Tsetsaut/Skii Km Lax Ha First Nation, the Tahltan Nation (as represented by the Tahltan Central Government), the Nisga'a Nation, through Nisga'a Lisims Government and the Alaska Department of Natural Resources.

5.3.4 Exceedances of the WTP discharge characteristics specified in section 1.2.3 are not non-compliance events. A non-compliance event would be not complying with requirements in section 1.2.4, which are triggered in the event of discharge characteristics in section 1.2.3 being exceeded.

5.4 Non-Compliance Reporting

5.4.1 If the permittee fails to comply with any of the requirements of this authorization, the permittee must, within 30 days of such non-compliance, submit to the director a written report that is satisfactory to the director and includes, but is not necessarily limited to, the following:

(a) All relevant test results obtained by the permittee related to the non- compliance,

(b) An explanation of the most probable cause(s) of the non-compliance, and

(c) A description of remedial action planned and/or taken by the permittee to prevent similar non-compliance(s) in the future.

5.4.2 The permittee must submit all non-compliance reporting required to be submitted under this section by email to the Ministry's Compliance Reporting Submission Mailbox (CRSM) at EnvironmentalCompliance@gov.bc.ca or as otherwise instructed by the director. For guidelines on how to report a non- compliance or for more information visit the Ministry website:

https://www2.gov.bc.ca/gov/content/environment/waste-management/waste-discharge-authorization/comply#reportnoncompliance

5.4.3 Non-compliance follow up reports must also be provided to the Tsetsaut/Skii Km Lax Ha First Nation, the Tahltan Nation (as represented by the Tahltan Central Government), the Nisga'a Nation, through Nisga'a Lisims Government and the Alaska Department of Natural Resources.

5.5 Annual Reporting

5.5.1 The permittee must submit to the director a comprehensive Annual Report by March 31st of each year, in a report format that follows directions of the "Technical Guidance 4 – Annual Reporting under the Environmental Management Act (2016)", or the most recent edition.

5.5.2 The Annual Report must be submitted to the Ministry (see section 5.2). Copies of the annual report must also be made available to the Ministry of Energy, Mines, and Low Carbon Innovation.

5.5.3 The Annual Report must include but not be limited to:

(a) an evaluation of the impacts of the discharge on the receiving environment, adequacy of monitoring and recommendations;

(b) spills and other environmental incidents;

(c) a comparison of monitoring data, including acute and chronic toxicity results, with Permit standards, BC Water Quality guidelines, and water quality modelling predictions;

(d) results of long-term toxicity sampling including plots of all data, trends in survival and growth, and a description of the results in the context of ecological effects in the receiving environment;

(e) an interpretation (including graphs) of upward trending parameters monitored and/or predicted to potentially exceed BC Water Quality guidelines, or Permit standards;

(f) results of water treatment operation and removal efficiency for all contaminants of potential concern;

(g) a summary of all non-compliances submitted in an Annual Status Form, mitigation and continuous improvement efforts employed by the mine;

(h) a summary of all surface water and groundwater quality, and hydrometric and groundwater levels for the previous year, including tables and graphs where appropriate to indicate trends in key water quality parameters, and including an assessment of relevant quality assurance data;

(i) flow measurements and discharge rates data for all authorized discharges, estimates of the amount and type of chemical additions (flocculants and chemicals used in the WTP and mill for ore processing and tailings thickening process);

(j) results and interpretations of receiving environment aquatic effects program monitoring, including: results and interpretations of acute and chronic toxicity testing, sediment and biological monitoring; analyses of key water quality trends; environmental effects; and assessment of the protectiveness of the discharge limits;

(k) results of any additional hydrogeological investigation and assessment work and updates to the groundwater model for the site;

(l) results and analyses of ongoing review of the site water quality predictions and source terms, water balance and water management at the site; and

(m) results of ongoing ML/ARD chemistry studies.

5.5.4 The annual report must also be provided to the Tsetsaut/Skii Km Lax Ha First Nation, the Tahltan Nation (as represented by the Tahltan Central Government), the Nisga'a Nation, through Nisga'a Lisims Government and the Alaska Department of Natural Resources.

5.6 **Mine Data and Water Quality Modelling Review**

5.6.1 Every five years during the operating life of the mine, or as required by the director in the event of significant changes with respect to monitoring results, production rates and or other factors, the permittee must conduct a review of the environmental monitoring required under this permit and reassess the predictive modelling with respect to the environmental impacts.

5.6.2 The permittee must ensure that the review be conducted by independent, third-party Qualified Professionals.

5.6.3 The permittee must cause the Qualified Professional to consider all the available data and any other information available to the permittee or Ministry of Environment staff. Each review will recommend what actions or permit amendments, if any, are advisable to limit impacts from the current or future activities at the mine site on the receiving environment and to ensure compliance with permit requirements.

5.6.4 The director shall consider these recommendations and may make amendments to the permit and/or the environmental monitoring plan that the director considers necessary for the protection of the environment.

5.6.5 A report summarizing the results of a five-year review must be submitted to the director and the Tsetsaut/Skii Km Lax Ha First Nation, the Tahltan Nation (as represented by the Tahltan Central Government), and the Nisga'a Nation, through Nisga'a Lisims Government by July 31st of the year in which the review is required. The first five-year review report is due on July 31, 2020.

5.7 Electronic Submission of Data into EMS

The permittee must cause a private laboratory or certified third party to electronically submit all the water quality data collected under this permit into the Environmental Management System (EMS) database on their behalf. For instructions on the electronic submission process or for more information visit the Ministry website:

https://www2.gov.bc.ca/gov/content/environment/research-monitoring-reporting/monitoring/environmental-monitoring-system

6. GLOSSARY

Capitalized terms referred to in this authorization are defined in the attached Glossary. Other terms used in this authorization have the same meaning as those defined in the Environmental Management Act and applicable regulations.

6.1 "Authorized Works"

"Authorized Works" means Brucejack Lake, low level weir, contact water pond, emergency spillway, contact water pond direct discharge line and outfall, tailings discharge line and outfall, water treatment plant, domestic

wastewater treatment plant, water treatment plant and domestic wastewater treatment plant effluent discharge line and outfall, collection works, ditches, pipelines, sumps, pumps, flow monitoring, water sampling, and related appurtenances at stated in sections 1.1.3, 1.2.5, 1.2.6, 1.3.3, 1.4.3, and 1.5.3.

6.2 **"Province"**

"Province" means His Majesty the King in right of British Columbia.

6.3 **"Regulatory Document**

"Regulatory Document" means any document that the permittee is required to provide to the Director or the Province pursuant to:

(i) this Authorization;

(ii) any regulation made under the Environmental Management Act that regulates the facility described in this Authorization or the discharge of waste from that facility; or

(iii) any order issued under the Environmental Management Act directed against the permittee that is related to the facility described in this Authorization or the discharge of waste from that facility.

6.4 **"Qualified Professional**

"Qualified Professional" means an applied scientist or technologist specializing in an applied science or technology applicable to the duty or function, including, if applicable and without limiting this, agrology, biology, chemistry, engineering, geology or hydrogeology and who:

(i) is registered with the appropriate professional organization, is acting under that organization's code of ethics and is subject to disciplinary action by that organization, and

(ii) through suitable education, experience, accreditation and/or knowledge, may be reasonably relied on to provide advice within their area of expertise.

All documents submitted to the Director by a Qualified Professional must be signed by the author(s).

sQtr 3 - Aug, Sept & Oct;
sQtr 4 - Nov, Dec & Jan.
Closure - Submit installation plan 2 years prior to closure

Metals & General* - Appendices A & B

Metals refers to:

1. Low level ICP or equivalent analysis of Total and Dissolved Metals including: Aluminum, Antimony, Arsenic, Barium, Beryllium, Bismuth, Cadmium, Chromium, Cobalt, Copper, Iron, lead, Lithium, Manganese, Molybdenum, Nickel, Selenium, Silver, Strontium, Thallium, Tin, Uranium, Vanadium and Zinc; and
2. Mercury analysis which are to be included at the Brucejack Lake outlet (BJ 3.10), the WTP effluent, the tailings supernatant; Site BJ 2.62, SCO, BJ 1.74, on a sQuarterly basis. The mercury sampling frequency at Site L3 outflow must be during freshet and fall.

General Parameters are defined as:

1. Laboratory analysis: pH, Specific Conductivity, Hardness, Alkalinity, Sulphate, Chloride, Fluoride, Calcium, Magnesium, Sodium, Ammonia, Nitrate, Nitrite, Total & Ortho Phosphorous, Total Organic Carbon, Total Suspended & Total Dissolved Solids, and Turbidity;
2. Field measurements: Turbidity, pH, Conductivity and Temperature;
3. Dissolved Phosphorous and Dissolved Organic Carbon which are to be included as part of the General Parameters at Sites BJ 3.10 & BJ 2.62 at a frequency of 3x/ ice free period, and 1x mid-winter;

Appendix 1-2: Final Joint Information Requirements Table

Joint Information Requirements Table

for

Mines Act and *Environmental Management Act* Permits

Prepared by:

British Columbia Ministry of Energy, Mines and Petroleum Resources

&

British Columbia Ministry of Environment and Climate Change Strategy

September 2019

Introduction

The Information Requirements Table (IRT) serves as the single list of information requirements for a *Mines Act* (MA) permit application, issued by the Ministry of Energy, Mines and Petroleum Resources (EMPR), and an effluent discharge permit application under the *Environmental Management Act* (EMA), by the Ministry of Environment (ENV). The IRT is intended to:

- Be used in conjunction with the document entitled, "Joint Application Information Requirements for *Mines Act* and *Environmental Management Act* Permits"[1] and is intended for use in the development of both new and/or permit amendment applications. The information contained within the IRT will be developed to meet the unique nature of each project.
- It is also to be used in conjunction with all other guidance provided by either ENV or EMPR[2].
- Inform clients of the detailed information required to support MA and EMA permit applications and ensure all the information necessary to support the MA and EMA applications is provided; and
- Aid ENV and EMPR technical staff during the screening phase.

Overview

The IRT is intended to aid proponents and reviewers through the coordinated authorizations review process: during the pre-application stage to determine the information requirements, prior to submitting an application, and in screening, to ensure the required information has been included in the application submission.

It is recommended that proponents carefully review the entire Joint Application Information Requirements for *Mines Act* and *Environmental Management Act* Permits and consider any possible information requirements that may apply to their project proposal. If a specific methodology from the Joint Application Information Requirements guidance document is being proposed, this should be identified in the IRT and initially be described at a high level by proponents during the pre-application stage. More detail or specific Information Requirements can be added by adding in new lines into the IRT in the appropriate section.

After proponents have created a first draft of the IRT, reviewers will carefully review the project

[2] https://www2.gov.bc.ca/gov/content/environment/waste-management/industrial-waste/mining-smelting This link does not lead directly to the referenced document : https://www2.gov.bc.ca/gov/content/environment/waste-management/industrial-waste/mining-smelting/guidance-documents

proposal and draft IRT prior to meeting with proponents to identify any missing information requirements or areas that require further discussion. The pre-application phase is most often an iterative set of discussions between the proponent and technical reviewers, regarding the information requirements and any specifics and/or methodologies that may be required in a joint MA/EMA permit application.

Once complete, the province will send the final IRT to proponents for their use in preparing their application. A copy of the IRT must accompany the application submission by proponents and must indicate the locations of each information requirement within the application (far right-hand column).

It is important to note that changes in a project proposal may occur during the pre-application, screening, and/or review phases of the process. These changes may require a reassessment of the information required for an application. Proponents and reviewers will work together to discuss these changes and identify any revisions or additional information requirements.

Information (refer to "Joint Application Information Requirements for *Mines Act* and *Environmental Management Act* Permits" for additional info on each section)	Requirements	Comments	Location in Final Application
1. INTRODUCTION AND PROJECT OVERVIEW			
1.1. Application Background	Required ☒ Methods ☐		Section 1.1
1.2. Proponent Information	Required ☒ Methods ☐		Section 1.3
1.3. Project Overview			
1.3.1. Project History	Required ☒ Methods ☐		Section 1.4.1
1.3.2. Overview of Products and Markets, and Projected Project Benefits	Required ☐ Methods ☐		N/A
1.3.3. Location, Access and Land Use	Required ☒ Methods ☐		Section 1.4.2
1.3.4. Mine Components and Off-Site Infrastructure	Required ☒ Methods ☐		Section 1.4.3
1.3.5. Mine Development and Operations	Required ☒ Methods ☒		Section 1.4.4
1.3.6. Mine Design and Assessment Team	Required ☒ Methods ☒		Section 1.4.5
1.3.7. Spatial Data	Required ☒ Methods ☐		Section 1.4.6
1.3.8. Concordance with Environmental Assessment Conditions	Required ☒ Methods ☐	Summary of concordance with EA Certificate M15-01 conditions.	Section 1.4.7
1.4. Regulatory Framework	Required ☒ Methods ☐	An outline of existing licences/permits/authorizations and which will be amended.	Section 1.5
1.5. Indigenous Engagement			
1.5.1. Background	Required ☒ Methods ☐		Section 1.6.1
1.5.2. Asserted and Established Rights and Interests	Required ☒ Methods ☐		Section 1.6.2
1.5.3. Engagement Efforts	Required ☒ Methods ☐		Section 1.6.3
2. BASELINE INFORMATION			
2.1. Summary	Required ☒ Methods ☒	1) Reference will be provided to previously submitted documents containing baseline information. 2) Will provide updated climate, water quantity and water quality characterizations based on monitoring data collected through 2021.	1) Section 2.1 and Chapter 2 subsections 2) Section 2.2 and Appendix 5-2 (Updated climate and water quantity characterizations), Appendix 5-3 (updated water quality characterization)
2.2. Meteorology and Climate	Required ☒ Methods ☒	1) Predicted effects of climate change on temperature and precipitation to 2100 will be included in the water balance model report. 2) Will provide the mine's tCO2 reported in 2021, including the 3rd party verification report for the 2021 reporting year.	1) Appendix 5-2 2) Appendix 2-1
2.3. Geology			
2.3.1. Regional Geology	Required ☒ Methods ☐		Section 2.3
2.3.2. Deposit (Ore) Geology	Required ☒ Methods ☐		Section 2.3
2.3.3. Surficial Geology, Terrain, and Geohazard Mapping	Required ☒ Methods ☐		Section 2.3
2.3.4. Natural and Seismic Hazards Assessments	Required ☐ Methods ☐		N/A
2.3.5. Soil Survey and Soil Characterization for Reclamation	Required ☐ Methods ☐		N/A
2.4. Geochemical Characterisation and Source Terms	Required ☒ Methods ☐		Section 2.4 and Appendix 5-3
2.4.1. Geochemical Characterization	Required ☒ Methods ☒	Summarized in Section 2.4 with reference to previously submitted documents. Additional characterization information will be provided in the source term section of the Water Quality Modeling Report.	Section 2.4 and Appendix 5-3 (Section 3)
2.4.2. Geochemical Source Terms	Required ☒ Methods ☒	Will provide this information in the Water Quality Modeling Report.	Section 3 of Appendix 5-3
2.5. Topography and Surface Drainage Features	Required ☒ Methods ☐		Section 2.5
2.6. Water Quantity			
2.6.1. Surface Water Quantity	Required ☒ Methods ☒	This information will be provided in the water balance modeling report that will be appended to the application and includes information	Section 2.6.1 and Appendix 5-2

Information (refer to "Joint Application Information Requirements for *Mines Act* and *Environmental Management Act* Permits" for additional info on each section)	Requirements	Comments	Location in Final Application
		regarding current surface water discharge volumes and a comparison to a potential increase in discharge volume resulting from the proposed production increase.	
2.6.2. Groundwater Quantity	Required ☒ Methods ☒	This information will be provided in the groundwater modeling report that will be appended to the application.	Section 2.6.2 and Appendix 5-1
2.7. Water Quality			
2.7.1. Surface Water Quality	Required ☒ Methods ☒	The Water Quality Modeling report will compare existing discharge concentrations to modeled concentrations, and to existing and proposed discharge limits for POPCs.	Section 2.7.1 and Appendix 5-3
2.7.2. Groundwater Quality	Required ☒ Methods ☒		Section 2.7.2 and Appendix 5-1
2.8. Sediment Quality	Required ☒ Methods ☐		Section 2.8
2.9. Fisheries and Aquatic Resources			
2.9.1. Periphyton and Benthic Invertebrate Community Measures	Required ☒ Methods ☐		Section 2.9.1
2.9.2. Fish and Fish Habitat	Required ☒ Methods ☐		Section 2.9.2
2.9.3. Tissue Residues	Required ☒ Methods ☐		Section 2.9.3
2.10. Ecosystems and Wildlife	Required ☐ Methods ☐		N/A
2.11. Land Status and Use	Required ☐ Methods ☐		N/A
2.12. Archaeology	Required ☐ Methods ☐		N/A
2.13. Cultural Use	Required ☐ Methods ☐		N/A
3. MINE PLAN			
3.1. Mine Plan Overview	Required ☒	1) Any changes to mining methods will be presented in the mine plan chapter. (No changes are proposed to mining methods.) 2) With respect to blasting agents, any changes will be incorporated into the nitrogen source terms described in the water quality model report. The specific locations where this information is provided will be identified in the Table of Concordance.	1) Sections 3.1 and 3.5 2) Section 3.8 of Appendix 5-3 (Nitrogen source terms)
3.2. Existing Development	Required ☒		Section 3.2
3.3. Life of Mine Plan	Required ☒		Section 3.3
3.4. Detailed Five Year Mine Plan	Required ☒	Mine plan vertical extents will be depicted in the mine plan chapter.	Section 3.4
3.5. Mine Facility Designs and Development	Required ☐		N/A
3.5.1. Open Pits	Required ☐		N/A
3.5.2. Underground Workings	Required ☒	1) The horizontal and vertical extents of the underground mine workings associated with the mine plan will be presented in the application. 2) A description will be provided of any changes in stope and/or drift sizing. (No changes are proposed.)	1) Section 3.3 and Section 3.4 2) Section 3.5 (no change)
3.5.3. Processing Plant (Mill) and Associated Facilities	Required ☒	Describe changes required for the proposed increased ore processing rate.	Section 3.1 (for summary of changes), Section 3.5
3.5.4. Tailings Storage Facility and Associated Infrastructure	Required ☒	1) Describe any changes to the WRTSF and associated infrastructure and operations with the 4950 tpd mine plan. This includes both the Waste Rock Dump (WRD) and tailings deposition within the WRTSF. [Note that the presented changes include subaqueous deposition of waste rock at the east end of the WRTSF (east WRD) and associated infrastructure (access and surface stockpile sites) that are proposed for existing operations and for which there will be applications for authorization outside of the 4950 tpd Joint Application process.	1) Sections 3.1, 3.4, and Section 3.5 2) Section 3.2 and Section 3.5 3) Sections 3.3 and 3.4 4) Appendix 3-2 and Appendix 9-1-17 5) Appendix 9-1-17 6) Appendix 9-1-17 7) Section 3.4 8) Appendix 3-1

Information (refer to "Joint Application Information Requirements for *Mines Act* and *Environmental Management Act* Permits" for additional info on each section)	**Requirements**	**Comments**	**Location in Final Application**
		2) The application will confirm that the capacity of current or updated mine waste storage facilities have the required capacities. 3) Mine progression figures included in the mine plan chapter will present the anticipated end of year footprints for waste rock dump and tailings within the WRTSF for 2022 through 2027, and the end of mine operations (2029). 4) Current methods used to manage and monitor pore water pressures based on dump performance and settlement in WRD during placement will be described, along with additional methods and instrumentation being considered to monitor pore water pressures. 5) The SOP for remote dozer placement of waste rock material is in the current OMS manual and details will be provided. 6) The Waste Rock and Tailings Storage Facility Operations, Maintenance and Surveillance (OMS) Manual will be provided, which includes a description of dump settlement monitoring. 7) The anticipated year by year increase in the tailings/WRD footprint will be provided via mine progression figures for end of 2022 through 2027, and the end of mine operations (2029). 8) Effects of increased processing rate on deposition of waste rock and tailings into the WRTSF will be described.	
3.5.5. Waste Rock Dumps	Required ☒	1) The information for both waste rock and tailings will be provided in a combined section as noted in the comments for section 3.5.4. 2) Preliminary design of the temporary waste stockpiles currently placed in the WRTSF will be described. The application will also describe other stockpile alternatives, such as a WRD and associated stockpiles proposed at the east end of the WRTSF that are needed for current mine operations and for which separate (from the 4950 tpd Joint Application) applications will be submitted. 3) Any aspects relevant to the production increase will be described. 4) Current waste rock management strategies will be described. 5) The application will also describe, to the extent that information is currently available, proposed waste rock management strategies that are aligned with the requirements set out in Permit condition D.3.(c).(v) and intended to fulfill requirements of open Order 185855-S1-O1. 6) The application will include life of mine extents of the waste rock and tailings based on the updated mine plan,	1) Section 3.5 2) Appendix 3-2 3) Section 3.5 and Appendix 3-1 4) Section 3.5, Appendix 3-1 and Appendix 9-1-17 5) Section 3.5 and Appendix 3-1 and Appendix 9-1-17 6) Section 3.4 7) Appendix 3-2 8) Section and Appendix 3-1

Information (refer to "Joint Application Information Requirements for *Mines Act* and *Environmental Management Act* Permits" for additional info on each section)	**Requirements**	**Comments**	**Location in Final Application**
		7) Stability analysis for the main waste rock dump and temporary surface stockpile, design assumptions and criteria based on current information available, and recommendations for additional geotechnical investigation, laboratory testing, instrumentation and liquefaction assessment. 8) The application will describe potential development of an additional subaqueous waste rock deposition site at the east end of the WRTSF (East WRD), proposed via separate authorization process because of its requirement for current operations, which is expected to address waste rock deposition requirements for operations at both the current and proposed production rates, and to address depletion of the current temporary waste stockpiles.	
3.5.6. Water Management Structures	Required ☒	1) Describe any changes to water management structures. 2) Information regarding increased rates of tailings and waste water discharges to Brucejack Lake will be provided in the Water Balance Model Report. 3) Any changes to water management structures due to the proposed production increase will be provided in the Water Management subsection of the Mine Plan chapter.	1) Section 3.1 (for summary of changes) and Section 3.5 2) Appendix 5-2 3) Section 3.1 (for summary of changes) and Section 3.5
3.5.7. Ore, Overburden, Soil and Construction Stockpiles	Required ☒		Section 3.2 and Section 3.5
3.5.8. Mine Access and Mine Haulage Roads	Required ☒	No mine access or haul road upgrades are required for the production rate increase. Proposed access to the (proposed) East WRD required for existing operations, and to be authorized via separate process, will be described.	Sections 3.1, 3.4, and 3.5
3.5.9. Power Supply and Distribution Infrastructure	Required ☒	Describe any changes to power supply requirements.	Sections 3.1 and 3.5
3.5.10. Explosives Storage Facilities	Required ☒	Describe any changes to explosives storage facilities.	Sections 3.1 and 3.5
3.5.11. Ancillary Facilities and Support Infrastructure	Required ☒	Describe any changes to ancillary facilities and support infrastructure.	Sections 3.1 and 3.5
4. RECLAMATION AND CLOSURE PLAN			
4.1. End Land Use and Capability Objectives	Required ☐	No change to existing.	Section 4.2 and Appendix 4-1 Section 2
4.2. Reclamation Approaches Required ☐ Comments Click here to enter text.			
4.2.1. Soil Resources	Required ☐	No change to existing reclamation approaches.	Section 4.3.2 and Appendix 4-1 Section 3.2
4.2.2. Landform Design and Erosion Control	Required ☐		Section 4.3.3 and Appendix 4-1 Section 3.3
4.2.3. Revegetation Strategy	Required ☐		Appendix 4-1 Section 3.4
4.2.4. Progressive Reclamation/Sequencing	Required ☐		Appendix 4-1 Section 3.5
4.2.5. Reclamation Research	Required ☐		Appendix 4-1 Section 3.6
4.2.6. Reclamation Monitoring	Required ☐		Appendix 4-1 Section 3.7
4.2.7. Habitat Compensation Works	Required ☐		N/A
4.3. Trace Element Uptake in Soils and Vegetation	Required ☐ Methods ☐		Appendix 4-1 Section 4
4.4. Contaminated Sites, Human Health and Ecological Risk Assessment	Required ☐ Methods ☐		Appendix 4-1 Section 5
4.5. Disposal of Chemicals, Reagents, Hazardous Materials and Contaminated Materials	Required ☐ Methods ☐		Appendix 4-1 Section 6
4.6. Groundwater Well Decommissioning	Required ☐ Methods ☐		Appendix 4-1 Section 7
4.7. Reclamation and Closure Prescriptions			

Information (refer to "Joint Application Information Requirements for *Mines Act* and *Environmental Management Act* Permits" for additional info on each section)	Requirements	Comments	Location in Final Application
4.7.1. Structures and Equipment	Required ☒	Existing reclamation and closure prescriptions will be updated as appropriate.	Section 4.4.2 and Appendix 4-1 Section 8.2
4.7.2. Waste Rock Dump Reclamation	Required ☒		Section 4.4.2 and Appendix 4-1 Section 8.3
4.7.3. Tailings Storage Facility Reclamation	Required ☒		Appendix 4-1 Section 8.3
4.7.4. Open Pit Reclamation Prescriptions	Required ☐		N/A
4.7.5. Watercourse Reclamation Prescriptions	Required ☒		Appendix 4-1 Section 8.4
4.7.6. Road Reclamation	Required ☒		Appendix 4-1 Section 8.8
4.7.7. Schedule	Required ☒		Section 4.4.1 and Appendix 4-1 Section 8.1.1
4.8. Detailed Five-Year Mine Reclamation Plan	Required ☒	Update as appropriate from 2020 Update based on 2029 end of operations.	Section 4.5 and Appendix 4-1 Section 10
4.9. Temporary Shutdown	Required ☐		Appendix 4-1 Section 11
4.10. Post-Closure Monitoring and Maintenance	Required ☒	Update as appropriate or state no change.	Section 4.6 and Appendix 4-1 Section 12
4.11. Reclamation Cost Estimate			
4.11.1. Conventional Reclamation and Closure	Required ☒		Section 4.7, submitted to the Chief Permitting Officer under separate cover as per Code Section 10.1.3(i).
4.11.2. Post-Closure Monitoring	Required ☒		Section 4.7, submitted to the Chief Permitting Officer under separate cover as per Code Section 10.1.3(i).
4.11.3. Post-Closure Maintenance (excluding Water Treatment)	Required ☒		Section 4.7, submitted to the Chief Permitting Officer under separate cover as per Code Section 10.1.3(i).
4.11.4. Life of Mine Water Treatment	Required ☒	The updated reclamation liability costing calculations to be submitted to BC EMLI will include updated costs for water treatment during mine closure while the underground mine floods, and for monitoring 5 years post closure.	Section 4.7, submitted to the Chief Permitting Officer under separate cover as per Code Section 10.1.3(i).
5. MODELLING, MITIGATION, AND DISCHARGES			
5.1. Summary	Required ☒		Section 5.1
5.2. Conceptual Site Model	Required ☒ Methods ☒	Pretium will provide documentation of the conceptual models and the new mine plan in sections within the respective stand-alone modeling reports (Water Balance, Groundwater and Water Quality).	Section 5.2 and appendices 5-1 (Groundwater Model Report), 5-2 (Water Balance Model Report), and 5-3 (Water Quality Model Report)
5.3. Site-Wide Water Balance Model	Required ☒ Methods ☒		Section 5.4 and Appendix 5-2
5.4. Surface Water Quality Model	Required ☒ Methods ☒	Existing model will be updated with updated water balance model, updated groundwater model, and updated source terms. A standalone surface water quality model report describing the modeling methods will be included as part of the application. The water quality model background source terms for the WRTSF include the historic input of Goldwedge to the WRTSF through Catear Creek, based on Brucejack Lake water quality data to 2013. This will be described in the Water Quality Model report.	Section 5.5 and Appendix 5-3
5.5. Groundwater Model			
5.5.1. Conceptual Hydrogeologic Model	Required ☒ Methods ☒	A standalone groundwater model report will be provided that includes documentation of field data that were used to support development of a conceptual groundwater model.	Appendix 5-1

Information (refer to "Joint Application Information Requirements for *Mines Act* and *Environmental Management Act* Permits" for additional info on each section)	Requirements	Comments	Location in Final Application
5.5.2. Numeric Hydrogeologic Model	Required ☒ Methods ☒	A full groundwater modeling report will be provided as an appendix of the Joint Application, with a summary provided in the main report chapter.	Section 5.3 and Appendix 5-1
5.6. Mitigation Methods	Required ☒		
5.6.1. Best Achievable Technology Evaluation	Required ☒ Methods ☒	A BAT study will be presented to evaluate treatment options at the outlet to the WRTSF for the POCs identified in Water Quality Model Report.	Section 5.6 and Appendix 5-4
5.6.2. Volume and Quantity Control Methods	Required ☐ Methods ☐		N/A
5.6.3. Geochemical Attenuation Processes	Required ☐ Methods ☐		N/A
5.6.4. Water Treatment			
5.6.4.1. Description	Required ☒	The current treatment plant and its ability to treat the anticipated water quality and water quantity predicted for the 4950 tpd production rate will be described.	Section 5.6 and Appendix 5 (Section 3.5)
5.6.4.2. Location	Required ☒		Sections 1.4 and 3.2
5.6.4.3. Detailed Design	Required ☒	Will be provided if changes are proposed.	N/A – No changes to existing water treatment are proposed
5.6.4.4. Treatment Effectiveness	Required ☒	If the production rate increase results in changes to influent quantity or quality the application will include an assessment of how those changes may affect treatment effectiveness.	Section 5.6.1
5.6.4.5. Performance Risks	Required ☒	This will be provided if changes are proposed.	N/A – No changes to existing water treatment are proposed
5.6.4.6. Influent and Effluent Water Quality	Required ☒	Any changes will be described.	Section 5.6 and Appendix 5-3
5.6.4.7. Waste and By-Products	Required ☒	This will be provided if changes are proposed.	N/A – No changes are proposed
5.6.4.8. Maintenance	Required ☒	This will be provided if changes are proposed.	N/A – No changes are proposed
5.6.4.9. Emergency Response Plans	Required ☒	This will be provided if changes are proposed.	N/A – No changes are proposed
5.6.4.10. Monitoring Plans	Required ☒	This will be provided if changes are proposed.	N/A – No changes are proposed
5.6.4.11. Schedule	Required ☒	This will be provided if changes are proposed.	N/A – No changes are proposed
5.6.4.12. Cost Estimate	Required ☒	This will be provided if changes are proposed.	N/A – No changes are proposed
5.7. Domestic Water/Sewage Treatment	Required ☒ Methods ☐	No changes to the existing STP are proposed. The application will conservatively include a request for a 4th sewage treatment unit to ensure continued full redundancy of one treatment unit in case discharge above 150 m3/d is required.	Clause change form – revised description of the treatment works. (No change is proposed to the current discharge rate of 175 m3/d.)
5.8. Effluent Discharge	Required ☒ Methods ☒	Characterization of effluent discharge water quantity and quality will be provided.	Effluent quantity – Section 5.4 and Appendix 5-2 Effluent quality – Section 5.5 and Appendix 5-3
5.9. Initial Dilution Zone	Required ☐ Methods ☐	An IDZ is not required if the discharge is not chronically toxic. QP documentation will be provided to support the current discharge limits and that the proposed discharge limits are not expected to cause the effluent to be chronically toxic.	N/A
6. ENVIRONMENTAL ASSESSMENT PREDICTIONS			
6.1. Aquatic Resources	Required ☒ Methods ☒	Nutrients will be included in the assessment provided.	Section 5 of Appendix 5-3
6.2. Terrestrial Resources	Required ☐ Methods ☐	No increase to surface disturbance expected with production increase.	N/A
7. ENVIRONMENTAL MONITORING			
7.1. Environmental Monitoring Program Design	Required ☒ Methods ☒	The production rate increase is not expected to require changes to existing environmental monitoring plans.	Section 7.1

Information (refer to "Joint Application Information Requirements for *Mines Act* and *Environmental Management Act* Permits" for additional info on each section)	Requirements	Comments	Location in Final Application
		The existing environmental monitoring program will be described.	
7.2. Mine Site Water Monitoring Program	Required ☒ Methods ☒		Section 7.2
7.3. Discharge Monitoring Program	Required ☒ Methods ☒	The existing discharge monitoring program is outlined in Effluent Permit 107835 and the Aquatic Effects Monitoring Plan (AEMP). Pretium will provide a summary of the program, with references to PE-107835 and the AEMP. Any proposed changes to the discharge monitoring program due to the proposed production increase will be described.	Section 7.3
7.4. Environment Monitoring Program	Required ☒ Methods ☒	The existing environmental monitoring program is outlined in Effluent Permit 107835, Air Permit 107025, Mines Act Permit M-243, in various other authorizations and in the Brucejack Mine EMS component management plans. Pretium will provide a summary of the program, with references to key authorizations and managements. In the case of groundwater, these include PE-107835 and the AEMP. Any proposed changes to the environmental monitoring program, including the groundwater monitoring program, due to the proposed production increase will be described.	Section 7.1
7.5. Cumulative Effects	Required ☐ Methods ☐	Pretium will meet with TCG to discuss cumulative effects. The water quality modeling includes cumulative historic effects of drainage from the Goldwedge site, as that is reflected in the baseline data.	N/A
7.6. Post-Closure Environmental Monitoring Program	Required ☒ Methods ☒	The proposed post-closure environmental monitoring program will be described in the updated Reclamation and Closure Plan that will be a stand-alone appendix of the application. Post-closure water quality predictions and related environmental effects assessments will be provided in the Water Quality Modeling Report.	Section 7.4 and Appendix 4-1
7.7. Aquatic Effect Monitoring Program	Required ☒ Methods ☒	The existing aquatic effects monitoring program is outlined in Effluent Permit 107835 and described in the Aquatic Effects Monitoring Plan (AEMP). Pretium will provide a summary of the program, with references to PE-107835 and the AEMP.	Section 7.5
8. HEALTH AND SAFETY			
8.1. Occupational Health and Safety Program			
8.1.1. Occupational Health Risk Assessment	Required ☐	The production rate increase does not require changes to existing occupational health and safety programs.	N/A
8.1.2. Ergonomics	Required ☐		N/A
8.1.3. Emergency Wash Facilities	Required ☐		N/A
8.1.4. Hazardous Dust	Required ☐		N/A
8.1.5. Lunchrooms, Mine Dry, and Sanitary Conveniences	Required ☐		N/A
8.2. Post-Permitting Requirements			
8.2.1. Issued for Construction Plans	Required ☐		N/A
8.2.2. Letters of Assurance	Required ☐		N/A
8.2.3. Occupational Health Programs	Required ☐		N/A
8.2.4. Workplace Hazardous Materials Information System (WHMIS)	Required ☐		N/A
8.2.5. Additional Information and Certifications	Required ☐		N/A
9. MANAGEMENT PLANS			
9.1. Environmental Management System	Required ☒	Any proposed changes to management plans will be described in the application. Consistent with previous applications and reviews, any required updates to management plans will be completed post-review to incorporate changes resulting from review.	Section 9.1

Information (refer to "Joint Application Information Requirements for *Mines Act* and *Environmental Management Act* Permits" for additional info on each section)	Requirements	Comments	Location in Final Application
		Pretium will describe the existing Environmental Management System, and any changes anticipated to be needed to existing component Management Plans due to the proposed production increase.	
9.2. Surface Erosion Prevention and Sediment Control Plan	Required ☒		Appendix 9-2
9.3. Soil Management Plan	Required ☒		Appendix 9-1
9.4. Construction Environmental Management Plan	Required ☒		N/A
9.5. ML/ARD Management Plan	Required ☒		Appendix 9-1
9.6. Mine Site Water Management Plan	Required ☒		Appendix 9-1
9.7. Discharge Management Plan	Required ☒	1) The BAT to be provided in accordance with comment ENV JIRT-6 for JIRT Section 5.6.4 will describe any recommended changes to water treatment and associated water management, however it is not currently anticipated that changes to either will be proposed. 2) The application will include a draft Trigger Response Plan that is based on monitoring at BJ 3.10, which is the outflow from the WRTSF and the headwaters of Brucejack Creek.	1) N/A No changes to water treatment are proposed 2) Section 5.9
9.8. Vegetation Management Plan	Required ☐		Appendix 9-1
9.9. Invasive Plant Management Plan	Required ☐		Appendix 9-1
9.10. Wildlife Management Plan	Required ☐		Appendix 9-1
9.11. Archaeological Management and Impact Mitigation Plan	Required ☐		Appendix 9-1
9.12. Mine Emergency Response Plan	Required ☐		Appendix 9-1
9.13. Mine Site Traffic Control Plan	Required ☐		Appendix 9-1
9.14. Fuel Management and Spill Control Plan	Required ☒	The proposed increase in production rate is not expected to require any changes to the Spill Response Plan, as spill response methodologies and other aspects of this plan are unlikely to require change. However, if changes to this or any other management plan are determined during the application review to be necessary, such changes will be made post-review.	Appendix 9-1
9.15. Combustible Dust Management Plan	Required ☐		N/A
9.16. Chemicals and Materials Storage, Transfer, and Handling Plan	Required ☒	The proposed increase in production rate is not expected to require any changes to the Chemicals and Materials Storage and Handling Plan, including because there are no plans to change reagents or other chemicals in relation to increasing the production rate. However, if changes to this or any other management plan are determined during the application review to be necessary, such changes will be made post-review.	Appendix 9-1
9.17. Waste (Refuse and Emissions) Management Plan	Required ☒	The relevant JIRT guidance document content requirements for a Waste (Refuse and Emissions) Management Plan are addressed through the Brucejack Mine's existing Air Quality Management Plan and Refuse Incinerator Management Plan. No changes to either management plan are expected to be needed in relation to the proposed 4950 tpd production increase. However, if changes to this or any other management plan are determined during the application review to be necessary, such changes will be made post-review. Dear Applicant:

Re: Confirmation of *Environmental Management Act* and *Mines Act* Authorizations Joint Amendment Application Information Requirements

This letter is to provide written confirmation of the application information that is required for your application to be considered complete and ready for consideration by the Mine Review Committee. This letter is your Application Instruction Document (AID) and details the information which must be included in your Final Application.

Technical Requirements

Attached you will find the final Information Requirements Table (IRT) which defines the technical aspects that should be included in your final application. A Technical Assessment Report which addresses all the information requirements in the IRT must be submitted with your Final Application. A copy of the final IRT must have the "Location in Final Application" column completed and be included with the final application. Guidance on how to prepare this report is available on the Ministry website[1].

To ensure professional accountability, the Ministry of Environment and Climate Change Strategy (ENV) requires that persons fulfilling legal requirements as qualified professionals (QPs) under ENV legislation must submit signed Declarations of Competency and signed Conflict of Interest Disclosure Statements. Completed declaration forms should be included in your final application. Each QP must provide declarations for the portion of the application for which they are responsible. Copies of the forms, and additional information, are available on the ENV website[2].

[1] Guidance Documents https://www2.gov.bc.ca/gov/content/environment/waste-management/industrial-waste/mining-smelting/guidance-documents.
[2] **QP forms and EPN Template** Apply for a waste discharge authorization - Province of British Columbia (gov.bc.ca)

Engagement Requirements

Indigenous Groups Consultation Requirements

The Project, as described in the Project Description dated July 22, 2022, is located within the traditional territory of the Tsetsaut Skii Km Lax Ha and Tahltan First Nations. It also has the potential to impact the Nass Wildlife Area of the Nisga'a Nation. Consultation with Indigenous groups is the responsibility of the Province of British Columbia and will be led by the Major Mines Office, Ministry of Energy, Mines and Low Carbon Innovation. It is recommended that Pretium Resources Inc. engage with the above identified First Nations throughout the authorization process.

Public Notification Requirements

The amendment application for the *Environmental Management Act* authorization is considered significant under the *Public Notification Regulation* (the Regulation)[3]. A completed Environmental Protection Notice[4] (EPN) must be submitted to ENV for review prior to posting or publication.

Notification must follow the procedures outlined in the Regulation, including:

- Posting notification as outlined in columns 4 and 5 of Schedule A;
- Posting on site;
- Notification of relevant municipalities (Terrace, Smithers and other towns that may experience an increase in air or road travel) and the Regional District of Kitimat-Stikine;
- Publication in the BC Gazette, Part I at the applicant's expense;
- Publication in local newspapers at the applicant's expense, including:
    - Smithers Interior News; and,
    - Terrace Standard;
- Publication of the application Technical Assessment Report in a format that is suitable for public access, such as a digital format available at a local public library or available online for download.

Notification and Engagement Report

Once notifications are complete and after the public comment period closes, a Notification and Engagement Report must be prepared for submission to ENV. The Notification and Engagement Report must be submitted during the application review phase. Guidance on the notification process is available on the ENV website[4].

Next Steps

Now that the Preliminary Application Phase is complete, it is up to you, the applicant, to prepare your final application for submission in accordance with the technical and engagement requirements identified in this AID.

[3] **Public Notification Regulation** https://www.bclaws.gov.bc.ca/civix/document/id/complete/statreg/202_94
[4] **Guidance on Notifications for Authorizations**: https://www2.gov.bc.ca/assets/gov/environment/waste-management/waste-discharge-authorization/guides/forms/7063_env_regionalops_notification_guide_web.pdf

The applicant should submit all documents for the final application package, including the final application forms to PermitAdministration.VictoriaEPD@gov.bc.ca, or via mail/courier to the addresses on the final application form. Final application forms and guidance on the application process for waste discharge authorizations are available on the ENV website[1].

If you have any questions, please contact the undersigned or Todd Adamsson at Todd.Adamsson@gov.bc.ca or 250-739-8393 and include your tracking number.

Yours truly,

Neil Bailey, P.Eng
Section Head, Northern Mining Authorizations
for director, *Environment Management Act*

1. Introduction

Pretium Resources Inc. (Pretium), a member of the Newcrest Group of companies, is the permittee for the Brucejack Mine, an underground gold mine located approximately 60 km NNW of Stewart, B.C. Pretium has submitted a joint application to amend *Mines Act* Permit M-243 and Effluent Permit 107835 for changes that would authorize an increase in the average daily ore production rate from the currently authorized 3800 tpd to 4950 tpd (4950 tpd Joint Application).

This report has been prepared to address a comment received from BC Ministry of Environment and Climate Change Strategy (ENV) during screening of the 4950 tpd Joint Application (Comment ID 1 in the information tracking table) that baseline (*i.e.*, prior to the permit amendment application) normal and extreme ranges of the following climate parameters be provided, at both monthly and annual intervals, including descriptions of the techniques used to determine them:

- Air temperature;
- Precipitation;
- Snowpack;
- Evaporation;
- Solar Radiation; and
- Wind Speed and Direction.

The sections that follow provide: 1) an overview of the Brucejack Meteorological Monitoring Program (MMP) (Section 2); 2) a discussion of the relevant steps taken to compile and process site-specific climate data (Section 3); and 3) a summary of relevant meteorological data collected at the Valley of King (VOK) meteorological station (Section 4), a station situated nearest the mine operation, at elevation 1,501 m asl.

It is noted that content presented in Section 2 and Section 3 of this report is synthesized from Meteorology Monitoring Reports (MMR) that are prepared annually (*e.g.*, Pretium 2021, Pretium 2022a and Pretium 2023). The reader is directed to these MMRs, and reports that precede them, for further detail regarding the Brucejack MMP.

The primary authorizations for construction and operation of the Brucejack Mine were received in 2015, including the CEAA 2012 Decision Statement, EA Certificate M15-01, *Mines Act* Permit M-243, Effluent Permit 107835 and amended Air Permit 107025. Construction began in late 2015. Baseline data for the period prior to construction are

documented in the EAC/EIS application (Rescan, 2013) and MA/EMA Permits Application (Pretium, 2015).

2. Brucejack Meteorological Monitoring Program

2.1 Background

The MMP aims to characterize current climate conditions in the immediate vicinity of the Brucejack Mine and associated infrastructure. The MMP is a component of the Air Quality Management Plan (Pretium 2022b) and a requirement of *Environmental Management Act* Permit PA-107025 (Discharge to Air) Section 5.3.

Meteorological data are routinely used to support daily activities at the mine site, such as air discharge operations and monitoring, avalanche forecasting and control, planning of water management activities, road maintenance and airstrip operations. Site-specific meteorological data are also primary inputs to technical evaluations conducted by Newcrest and their technical consultants (*e.g.*, Brucejack groundwater model and the Brucejack site-wide water balance and water quality model).

2.2 Monitoring Network

The Brucejack MMP has been ongoing since 2009 to characterize on-site meteorological conditions. In 2009, focus was placed on initiating monitoring in the deposit area, near the former Brucejack Lake, with the installation of the Brucejack meteorological station. In 2010 and 2011 the MMP expanded with the installation of the Scott Creek and Wildfire meteorological stations in response to evolving infrastructure development plans.

In August and September 2014, the three historical climate stations were decommissioned, and stations were re-established at new locations (Table 2-1, Figure 2-1). The former Brucejack meteorological station was moved 1 km to the southeast within the Valley of Kings (VOK) and is referred to herein as the VOK meteorological station. Owing to the near proximity of this station to the mining operation, the climate tables and time series plots presented in Section 4 of this report are for VOK meteorological station.

The Scott Creek meteorological station was relocated to an area adjacent to the Brucejack Access Road (BJAR) at road Kilometer 49.5 and was renamed Bowser meteorological station. The Bowser station location is useful in providing weather conditions for the Bowser aerodrome. The Wildfire meteorological station equipment was moved to an area adjacent to the BJAR at road Kilometer 18 and renamed Scott Pass meteorological station. The Scott Pass location was chosen to provide weather information along the Access Road.

In May 2016, a new station consisting of a ceilometer and visibility sensor was installed in Bowser camp to measure cloud ceiling heights and visibility in support of aircraft traffic at

Bowser Aerodrome (Bowser Lake Air, Table 2-1). In December 2019, a new station (DMZ) measuring air temperature, barometric pressure, wind speed, snow depth, and precipitation was commissioned near kilometer 60 of the Brucejack Access Road to support avalanche forecasting and control operations.

Regarding local snow surveys, a ten-point snow course was established adjacent the VOK meteorological station in 2015 (Table 2-1,Figure 2-1). Snow course surveys are conducted here following guidelines by BC MOE (BC MOE 1981). On each survey, up to ten snow cores are taken along a 250 m long transect at intervals ranging between 18 and 44 m. The cores are then used to calculate the average snow densities and snow water equivalents (SWEs) for the sampling date.

Finally, VOK and BJC snow plots (Table 2-1) are used by the Brucejack Mountain Safety team to collect manual snow depth observations. Daily manual data from the snow plots are used to supplement data for the VOK meteorological station when the automated snow depth sensor at the climate tower malfunctions.

Table 2-1:
Meteorological Station Locations and Operating Periods

Meteorological Station	Elevation (masl)		UTM Coordinates[1]		Operating Period	
		Status	Easting (m)	Northing (m)	Start	End
Brucejack Lake	1,360	Historical	425,729	6,259,022	Oct. 13, 2009	Aug. 30, 2014
Scott Creek	780	Historical	451,418	6,254,104	July 29, 2010	Aug. 27, 2014
Wildfire Creek	720	Historical	470,397	6,256,874	Aug. 13, 2011	Aug. 26, 2014
VOK[2]	1,501	Current	426,301	6,258,276	Sept. 2, 2014	Active
Bowser	440	Current	443,003	6,250,540	Sept. 4, 2014	Active
Scott Pass	990	Current	456,394	6,262,968	Sept. 5, 2014	Active
Bowser Lake Air	450	Current	441,427	6,250,228	May 12, 2016	Active
DMZ	1,277	Current	436,731	6,253,311	Dec 9, 2020	Active
VOK Snow Plot	1,470	Current	428,710	6,258,156	Sept 21,2021	Active
BJC Snow Plot	1,420	Current	426,747	6,258,499	Oct 12, 2021	Active

Figure 2-1: Locations of Meteorological Stations and Snow Course Surveys, Brucejack Mine

2.3 Station Instrumentation

Table 2-2 lists the climate parameters monitored at the continuously recording meteorological stations (*i.e.*, the VOK, Bowser and Scott Pass stations). Two-way satellite telemetry systems are installed on each station. These communication systems allow for automated remote downloading of data, faster identification of instrumentation issues, and more informed planning for field visits. Each satellite telemetry system includes a Moxa 5110 server and a Hughes 9502 terminal and antenna.

Combination temperature and relative humidity sensors (either Rotronic HC2-S3 or Vaisala HMP45C212) are mounted on each tower, approximately three to five meters above the ground (to prevent burial in the snowpack) and are protected from solar radiation by a multi-plate solar radiation shield (RM Young model 41003).

Geonor Model T-200B all-season precipitation gauges are used to measure liquid precipitation (*i.e.*, rainfall) and solid precipitation (i.e., snowfall; measured as SWE). The gauges are each mounted on 2.5 m high pedestals complete with a single Alter wind screen to help reduce wind-induced undercatch.

Local snow depths are monitored by Campbell Scientific model SR50A acoustic distance sensors mounted to each station tower at the Bowser and Scott Pass stations. At VOK meteorological station, the SR50A is mounted to a separate tower approximately 15 m away from the main tower.

Incoming solar radiation (direct and indirect short-wave radiation from the sky) is monitored using Kipp & Zonen SP Lite or SP Lite 2 pyranometers, whereas barometric pressure is monitored using RM Young models 61205V or 61302 barometric pressure sensors mounted inside respective datalogger enclosures.

Wind speed and direction are measured at the three continuously recording meteorological stations with RM Young Model 05305 wind sensors installed at the top of the steel towers - at a height of 10 m above the ground. This is the standard height for the collection of wind speed and wind direction data (EC 2012; WMO 2018; BC MOE 2016).

Climate sensors at each station are wired to Campbell Scientific dataloggers. A datalogger program scans each sensor at 5 second intervals and generates hourly and daily data tables along with instantaneous, average, maximum, minimum, total, and standard deviation values, depending on the meteorological variable. Data saved to the dataloggers are stored in internal memory as well to a compact flash card connected to each datalogger.

Pretium conducts periodic site visits to ensure ongoing and proper functioning of the meteorological stations. Maintenance and/or troubleshooting is conducted as needed with

summaries of site visit and sensor maintenance tasks reported in MMRs (*e.g.*, Pretium 2023).

Table 2-2:
Variables Monitored at Brucejack Meteorological Stations

Variable	Meteorological Station		
	VOK	**Bowser**	**Scott Pass**

Relative Humidity	✓	✓	✓
Precipitation (Rainfall + SWE[1])	✓	✓	✓
Wind Speed and Direction	✓	✓	✓
Incoming Solar and Net Radiation	✓	✓	✓
Barometric Pressure	✓	✓	✓
Snow Depth	✓	✓	✓

[1] – *Snow water equivalent (SWE)*

3. Data Processing and Method

3.1 Initial Screening

To prepare the climate data summary presented in Section 4, Lorax received copies of the daily- and hourly output files for the VOK meteorological station. These data spanned the period September 2, 2014, through October 19, 2023, and are managed by Newcrest using Aquarius Time Series™ software (v. 21.4., Aquatic Informatics Inc.). The Aquarius Time Series™ software platform is a centralized database specifically designed for the storage, management, and analysis of climatic and hydrologic data, and is widely used by water monitoring agencies such as the Water Survey of Canada (WSC) and ENV.

QA/QC algorithms are implemented in Aquarius, based on screening criteria by ECCC (EC 2004) and ERM (2018), to screen raw data that is offloaded from the Brucejack meteorological stations. Further, Lorax understands that data stored in Aquarius are reviewed periodically to ensure proper operation of the station sensors. Erroneous data are flagged and removed from the finalized reported dataset to the extent possible, with significant periods of flagged erroneous or missing data for the station discussed in annual MMRs.

3.2 Data Processing

Data received from Newcrest were further inspected upon receipt to identify erroneous or missing information. Next, pivot tables of the hourly climate records were computed to determine level of completeness. Computed completeness thresholds were very high for most parameters: *e.g.*, air temperature (99%); relative humidity (99%); solar radiation (100%); atmospheric pressure (97%); and wind speed and direction (99%).

Using hourly data as the input, pivot tables were then compiled at monthly/annual time steps to isolate averages and extremes (*i.e.*, maximum and minimum values) for key variables at the VOK meteorological station. Several time series plots were also prepared to demonstrate data completeness and any patterns/trends per climate variable for the 9+ years of record available for VOK meteorological station.

While daily/hourly data for October 2023 are shown in the time series plots presented in Section 4, monthly pivot table values for October 2023 are removed because data for this month are incomplete.

3.3 Precipitation

Lorax received infilled and adjusted precipitation data for VOK meteorological station current to August 16, 2023, to complete this technical report. Since precipitation data for August 2023 were only 52% complete, pivot tables presented in Section 4 for precipitation variables exclude reporting for this month.

3.3.1 Wind Induced Precipitation Undercatch Adjustment

Most precipitation gauges are affected by wind undercatch which is an underestimation attributable to wind turbulence around the gauge opening prevents precipitation particles from entering the gauge. Wind turbulence especially affects lighter solid precipitation particles (*i.e.*, snow). To account for precipitation underestimation caused by wind undercatch, the 2017 Meteorology Monitoring Report (ERM 2018) evaluated different undercatch equations and determined the equation developed by McDonald and Pomeroy (2007) was best suited for the snowfall characteristics of the BC coastal region.

This equation was used for daily precipitation adjustments in this report and is described below:

$$CE = 1.01 \times \exp(-0.09 \times U)$$

where CE is the catch efficiency of a single Alter wind screen Geonor precipitation gauge referenced to true snowfall, and U is the wind speed (m/s) at the Geonor orifice gauge height. The undercatch equation was not applied to rainfall as the catch efficiency is near 100% for all wind speeds (ERM 2018).

Because each catch efficiency equation requires wind speed at the precipitation gauge orifice, the logarithmic wind profile (assuming neutral vertical stability; refer to Stull 2016) was used to estimate precipitation gauge orifice height wind speeds. The following logarithmic wind profile equation is used at the Brucejack Mine:

$$U_2 = U_1 \times (\ln(z_2/z_0) / \ln(z_1/z_0)$$

Values for these coefficients were assumed as follows: z_0 as 0.017 m, z_1 as 10 m, U_1 as the daily mean wind speed (m/s) measured at 10 m above the ground, and z_2 is the height of the Geonor precipitation gauge orifice above the ground (3.3 m at VOK, and 3.6 m at Bowser and Scott Pass).

A detailed description of these undercatch coefficients is provided in the 2017 Meteorology Monitoring report (ERM 2018).

3.3.2 Estimating Missing Precipitation Data

The equations shown in Table 3-1 are reproduced from the 2021 MMR (see Pretium 2022a for more detail). When necessary, missing precipitation, temperature, and snow depth data are estimated using linear equations based on established relationships developed from data collected at the VOK, Bowser and Scott Pass meteorological stations.

The precipitation equations were derived using orthogonal correlation on concurrent historical monthly precipitation datasets (2014 to 2021) among all three stations. Orthogonal correlation was used to derive the resulting equations because the method yielded better R values than simple linear correlation. The precipitation equations were developed using total monthly precipitation datasets and were applied to the daily dataset by dividing the derived intercept values by the average number of days per month (30.5). When applying these equations, any resulting negative precipitation values were set to zero.

Table 3-1:
Example correlations to infill missing climate data, Brucejack Meteorological Monitoring Program

Dependent Variable	Independent Variable	Equation	Correlation Coefficient (R)	Dataset	No. of Pairs
Precipitation (mm)					
P_{Bowser}	$P_{ScottPass}$	$P_{Bowser} = 1.17 \times P_{ScottPasss} - (10/30.5)$	0.94	2014 - 2021	63
P_{VOK}	$P_{ScottPass}$	$P_{VOK} = 1.24 \times P_{ScottPasss} - (8.72/30.5)$	0.91		63
P_{VOK}	P_{Bowser}	$P_{VOK} = 1.10 \times P_{ScottPasss} - (16.68/30.5)$	0.86		64
Temperature (°C)					
$T_{ScottPass}$	T_{VOK}	$T_{ScottPass} = 1.144 \times T_{VOK} + 3.311$	0.98	2021	356
T_{Bowser}	T_{VOK}	$T_{Bowser} = 1.082 \times T_{VOK} + 5.044$	0.92	2021	356
T_{VOK}	T_{Bowser}	$T_{VOK} = 0.655 \times T_{Bowser} - 3.288$	0.91	2021	356
Snow Depth (m)					
SD_{VOK}	$SD_{SnowPlot}$	$SD_{VOK} = 0.7607 \times SD_{SnowPlot} + 0.1912$	0.98	2020-2021	164

Note: Any resulting negative precipitation estimates were set to zero.

3.4 Potential Evaporation

Potential evaporation estimates prior to May 30, 2023, were computed for the VOK meteorological station using measured climate data and the Ref-ET calculator - a compiled, stand-alone computer program that calculates reference evapotranspiration (ASCE, 2005). An hourly input file was prepared for Ref-ET based on measured data for the following parameters: air temperature, relative humidity, incoming solar radiation, atmospheric pressure, and wind speed.

From the assembled climate inputs, Ref-ET returns potential evaporation (PE) computations at daily time-step for an array of evaporation models. Outputs based on the ASCE Standardized Reference Evapotranspiration Equation are reported in Section 4 of the report. The VOK meteorological station was re-programmed on June 1, 2023, and now computes and compiles daily estimates of potential evaporation using the ASCE 2005 formulation.

4. Results

4.1 Air temperature

The following air temperature summaries are presented in this section of the report:

- Average air temperature measurements are presented for the VOK meteorological station at monthly and annual time step (Table 4-1).
    - On average, July and August are the warmest months at the mine site (7.8°C), whereas December (-8.3°C) and February (-8.4°C) are the coldest.
    - A mean annual temperature (MAT) estimate of -0.9°C was computed for VOK meteorological station based on the record period available (*i.e.*, September 2014 through September 2023).
- Table 4-2 summarizes the maximum hourly temperature readings recorded by month and year at VOK meteorological station for the record period.
- Table 4-3 summarizes the minimum hourly temperature readings recorded by month and year at VOK meteorological station for the record period.
- In Figure 4-1, maximum-, average- and minimum daily air temperature readings at VOK meteorological station (September 2014-October 2023) are plotted in time series format.
- Figure 4-2(upper panel) presents the daily averaged air temperature signature for VOK meteorological station (based on 9 years of data; 2014-2023) whereas Figure 4-2 (lower panel) presents the monthly average air temperature signature for VOK.

4.2 Precipitation

The following precipitation summaries are presented in this section of the report:

- Monthly and annual precipitation depths recorded at VOK meteorological station are presented in Table 4-4.
  - On average, October (259 mm) and November (233 mm) are the wettest months at the mine site, whereas May (85 mm), June (93 mm) and July (95 mm) are the driest months.
  - A mean annual precipitation (MAP) estimate of 1,820 mm was computed for VOK meteorological station based on the record period available (*i.e.*, September 2014 through August 2023).
    - The least amount of precipitation was recorded in the 2018 calendar year (1,224 mm) versus the most precipitaiton which was recorded in the 2021 calendar year (2,143 mm).
- In Figure 4-3, daily precipitation readings are plotted for the VOK meteorological station between September 2014 and August 2023.
  - More than ten daily precipitation depths were in excess of 60 mm, four precipitation depths were in excess of 80 mm, and one precipitation depth was recorded in excess of 110 mm.
- Figure 4-4 (upper panel) presents the daily averaged precipitation signature for VOK meteorological station (based on 9 years of data; 2014-2023) whereas Figure 4-4 (lower panel) presents the monthly average precipitation signature for VOK.

4.3 Snow depth Readings and Snow Surveys

The following snow depth summaries are presented in this section of the report:

- Average snow depth readings are presented for the VOK meteorological station at monthly and annual time step (Table 4-5).
  - On average, snow depths reach their annual maxima in March (3.3 m) and April (3.4 m), with melt out of snow storage occurring typically by June or July.
  - A mean annual temperature (MAT) estimate of -0.9°C was computed for VOK meteorological station based on the record period available (*i.e.*, September 2014 through September 2023).
- Table 4-6 summarizes the maximum hourly snow depth readings recorded by month and year at VOK meteorological station for the record period.
- Table 4-7 summarizes the minimum hourly snow depth readings recorded by month and year at VOK meteorological station for the record period.
- Daily snow depth readings at VOK meteorological station (2015-2023) are presented in time series format in Figure 4-5.
- In Figure 4-6, median, 2nd percentile, 10th percentile, 90th percentile and 98th percentile snow depth summaries are plotted for the VOK meteorological station (based on 9 years of data; 2014-2023).
- A map demarcating the VOK snow course is presented in Figure 4-7. Snow course data (*i.e.*, snow depth, SWE and snow density) collected at the snow course since 2015 is presented in Table 4-8.

Table 4-5:

4.4 Relative Humidity

The following relative humidity summaries are presented in this section of the report:

- Average relative humidity estimates are presented for the VOK meteorological station at monthly and annual time step (Table 4-9).
- Table 4-10 summarizes the maximum hourly relative humidity readings recorded by month and year at VOK meteorological station for the record period.

- Table 4-11 summarizes the minimum hourly relative humidity readings recorded by month and year at VOK meteorological station for the record period.
- In Figure 4-8, maximum-, average- and minimum daily relative humidity readings at VOK meteorological station (September 2014-October 2023) are plotted in time series format.

Table 4-9:
Average relative humidity readings at VOK meteorological station (2014-2023).

	Average Relative Humidity (%)												
Year	**Jan**	**Feb**	**Mar**	**Apr**	**May**	**Jun**	**Jul**	**Aug**	**Sep**	**Oct**	**Nov**	**Dec**	**Annual**

4.5 Solar Radiation

The following solar radiation summaries are presented in this section of the report:

- Average solar radiation estimates are presented for the VOK meteorological station at monthly and annual time step (Table 4-12).
- Table 4-13 summarizes the maximum hourly solar radiation readings recorded by month and year at VOK meteorological station for the record period.
- Table 4-14 summarizes the minimum hourly solar radiation readings recorded by month and year at VOK meteorological station for the record period.
- In Figure 4-9, maximum-, average- and minimum daily solar radiation readings at VOK meteorological station (September 2014-October 2023) are plotted in time series format.

4.6 Atmospheric Pressure

The following atmospheric pressure summaries are presented in this section of the report:

- Average station pressure readings are presented for the VOK meteorological station at monthly and annual time step (Table 4-15).
- Table 4-16 summarizes the maximum hourly station pressure readings recorded by month and year at VOK meteorological station for the record period.
- Table 4-17summarizes the minimum hourly station pressure readings recorded by month and year at VOK meteorological station for the record period.
- In Figure 4-10, maximum-, average- and minimum daily station pressure readings at VOK meteorological station (September 2014-October 2023) are plotted in time series format.

4.7 Wind Speed and Direction

The following atmospheric pressure summaries are presented in this section of the report:

- Average wind speed readings are presented for the VOK meteorological station at monthly and annual time step (Table 4-18).
- Table 4-19 summarizes the maximum hourly wind speed readings recorded by month and year at VOK meteorological station for the record period.
- Table 4-20 summarizes the minimum hourly wind speed readings recorded by month and year at VOK meteorological station for the record period.
- In Figure 4-11, maximum-, average- and minimum daily wind speed readings at VOK meteorological station (September 2014-October 2023) are plotted in time series format.
- Annual wind rose and wind speed summaries (Figure 4-12) and an annual wind class frequency distribution (Figure 4-13) are presented for the VOK meteorological station based on the available record period.
- Monthly wind rose/wind speed summaries and monthly wind class frequency distributions (i.e., January through December) are also presented for the VOK meteorological station (see Figure 4-14 through Figure 4-37 inclusive).

Table 4-18:

4.8 Potential Evaporation

The following potential evaporation summaries are presented in this section of the report:

- Monthly and annual potential evaporation estimates are presented for VOK meteorological station for the available record period (Table 4-21).
  - Monthly potential evaporation depths are highest, on average, during months of May, June, July and August.
  - Long-term average rates of potential evaporation are estimated to be 296 mm (May-September) and approximately 400 mm annually.
- In Figure 4-38, daily potential estimates computed for VOK meteorological station (September 2014-October 2023) are plotted in time series format.

Table 4-21:
Monthly and annual potential evaporation estimates for VOK meteorological station (2014-2023).

	Potential Evaporation (mm)													
Period	**Jan**	**Feb**	**Mar**	**Apr**	**May**	**Jun**	**Jul**	**Aug**	**Sep**	**Oct**	**Nov**	**Dec**	**May-Sep**	**Ann**
2014	---	---	---	---	---	---	---	---	34	15	15	9	---	---
2015	9	15	25	40	94	76	64	46	23	14	12	6	303	423
2016	9	9	26	39	69	69	60	54	24	12	3	4	277	379
2017	5	11	15	45	62	58	61	68	34	14	4	4	283	382
2018	1	8	22	39	68	73	91	60	37	15	5	2	330	422
2019	4	12	36	44	83	73	25	60	33	12	5	5	275	394
2020	5	7	25	43	70	57	55	32	36	11	7	5	249	352
2021	5	7	16	51	63	83	76	49	21	19	6	4	291	400
2022	5	9	20	39	69	89	67	62	32	16	9	4	320	422
2023	5	5	22	35	78	79	86	---	---	---	---	---	---	---
Average (2014-2023)	6	9	23	42	73	73	65	54	31	14	7	5	296[1]	401

[1]This potential evaporation estimate compares well to the 30-yr (1991-2020) May-September estimate of 279 mm returned by ClimateBC (https://climatebc.ca/) for a grid point and elevation corresponding to the VOK climate station.

Figure 4-38: Daily potential evaporation estimates for VOK meteorological station (September 2014-August 2023).

5. Closure

We trust this report meets your requirements at this time. Please contact us should you have any questions or concerns or require additional information in support of this work.

Yours sincerely,

Verification Report and Statement – Version 2.0
Greenhouse Gas Emission Reporting Regulation – B.C. Regulation 249/2015 – ANAB Accreditation under ISO 14065
2021 Emission Report for the Facility

Dear Ms. Moore:

Dillon Consulting Limited (Dillon) is pleased to present Newcrest Mining Limited (Newcrest) with this Verification Report under British Columbia Greenhouse Gas Emission Reporting Regulation (B.C. Reg. 249/2015 [the Regulation]) under the *Greenhouse Gas Industrial Reporting and Control Act* for the Brucejack Gold Mine Facility, located north of Stewart, British Columbia, Canada (Facility or Site). The Facility is registered with the BC Ministry of Environment (MOE) and Climate Change Strategy with BCGHG ID # 22122200002.

The Facility used quantification methodologies developed in consideration of British Columbia Greenhouse Gas Emission Reporting Regulation (Regulation), CleanBC Industrial Incentive Program Guideline and the Western Climate Initiative (WCI) *Final Essential Requirements of Mandatory Reporting: Amended for Canadian Harmonization* (2011).

Dillon has reviewed production numbers in support of the CleanBC Industrial Incentive Program (CIIP) application, however was unable to review the final CIIP report as it was not available for review before May 31, 2022. As a result, we have not provided a statement in regards to the CIIP production at this time. Dillon will provide an updated report once the CIIP application report has been provided.

Please contact Zachary Zehr at 226.752.9319 or zzehr@dillon.ca, should you have any questions.

Sincerely,

DILLON CONSULTING LIMITED

Zachary Zehr, P.Eng.

1.0 Verification Overview

1.1 Introduction

Dillon Consulting Limited (Dillon) presents Newcrest Mining Limited (Newcrest) (formerly Pretium Exploration Inc.) with this Verification Report for Greenhouse Gas (GHG) Inventory and CIIP Verification Services under British Columbia Greenhouse Gas Emission Reporting Regulation (B.C. Reg. 249/2015 [the Regulation]) under the *Greenhouse Gas Industrial Reporting and Control Act* for the Brucejack Gold Mine Facility, located north of Stewart, British Columbia, Canada (Facility or Site). In particular, the scope involves the verification of the Facility's 2021 Emission Report and CIIP Production.

1.2 Objectives

The objectives of this assignment are to provide Newcrest and BC MOE Climate Action Secretariat (CAS) (the Regulator) with a reasonable level of assurance, independent, third party verification, and opinion on whether the Facility's 2021 Emission Report and Production Data under the CleanBC Industrial Incentive Program (CIIP) is free of material misstatements, as well as that the information reported is accurate and consistent with the requirements of the Regulation.

1.3 Verification Scope

The following is a summary from the 2021 Emission Report scope for the Facility.

Time Period – January 1, 2021 through December 31, 2021.

Geographic and Organizational Boundaries: This scope includes the emissions generated and 2021 production at the Facility at the physical address as listed below. The emissions are related to specific GHG activities listed in the Regulation and emitted by the Facility. The Facility is located at the following address:

56°27'55.94"N, 130°11'10.06"W
Approximately 65 km north of Stewart
Regional District of Kitimat-Stikine, British Columbia

Activities and Processes: The Facility is an underground high-grade gold mine. The operations and camps are connected to the BC Hydro power grid with full diesel backup generation capacity. The Facility includes three (3) active camp sites, and one (1) closed camp site: Wildfire Camp, Knipple Camp, Brucejack Camp, and Bowser Camp (closed). Operations on-site include:

- WCI.280 – Mobile Equipment at Facilities:
  - Diesel in heavy equipment; and
  - Gasoline in off-road mobile equipment;
- WCI.020 – General Stationary Combustion:
  - Diesel in backup generators;

  - Propane in space heaters;
  - Waste materials in incinerator; and
  - Open burning of wood waste; and
- WCI.200 – Wastewater treatment on-site.

GHG Emission Sources, Categories, and GHG Types: The applicable Facility GHG activities are provided in **Table A** (attached).

Organizational-level Sector: 2 – Mining and mineral production.

1.4 Level of Assurance and Materiality

The verification was conducted to a reasonable level of assurance, per the requirements of the Regulation and CIIP.

The materiality threshold for the Facility was set at plus or minus 5% of the Emissions reported in 2021, consistent with Section 32 of the Regulation. The materiality threshold for the Facility under the CIIP was set at plus or minus 5% of the 2021 Production Data.

BC Regulation requires that net of all over or understatements cannot exceed the lesser of 1,000 tonnes of CO_2e or 1% of the total emissions. In addition, CIIP requires that all correctable errors be corrected and that the aggregate effects of error results in any inaccuracy be no greater than 0.1%.

Individual errors, omissions, misstatements, or the aggregation of discrete errors, omissions, or misstatements, were considered material. As further described in **Section 4.0** and **Section 5.0**, the Facility's 2021 Reported Emissions and Production Data did not exceed the materiality threshold.

1.5 Verification Criteria

Dillon conducted the verification in accordance with the requirements and criteria outlined in the Regulation, including the following:

- *ISO 14064-1:2018 – Part 1: Specification with guidance at the organization level for quantification and reporting of GHG emissions and removals,* ISO, December 2018;
- *ISO 14064-3:2006 – Part 3: Specification with guidance for the validation and verification of GHG assertions,* ISO, March 2006;
- SBC 2014, Chapter 29: *Greenhouse Gas Industrial Reporting and Control Act*, current to January 20, 2021;
- CleanBC Industrial Incentive Program (CIIP) Guidelines;
- BC Regulation 249/2015: *Greenhouse Gas Industrial Reporting Regulation: Greenhouse Gas Emission Reporting Regulation (Regulation),* as amended by BC Reg. 294/2020, December 21, 2020;
- B.C. Regulation 231/2019: *Greenhouse Gas Industrial Reporting and Control Act*;

- Western Climate Initiative (WCI) *Final Essential Requirements of Mandatory Reporting: Amended for Canadian Harmonization*, December 17, 2010;
- WCI *2011 Amendments for Harmonization of Reporting in Canadian Jurisdictions*, December 21, 2011; and
- WCI *Quantification Method 2013 Addendum to Canadian Harmonization version*, December 10, 2013.

2.0 Verification Body and Verification Team

Table 1 below provides an overview of the Verification Body (VB), Dillon Consulting Limited. **Table 2** below provides details regarding the Verification Team.

Table 1: Verification Body Overview

Name	Dillon Consulting Limited
Mailing and physical address	51 Breithaupt St, Kitchener, ON N2H 5G5
Contact information	Zachary Zehr zzehr@dillon.ca 519-571-9833
Accrediting agency	ANAB
Accreditation ID	8896

Table 2: Verification Team Overview

Verification Team	
Lead Verifier and Technical Expert	Zachary Zehr, P.Eng.
Contact Information	zzehr@dillon.ca , 519-571-9833
Additional Qualifications	Zach is a licensed professional engineer in Ontario, and has a Bachelor of Engineering in Environmental Engineering from the University of Guelph. Zach has more than eight years of experience working in a variety of air and noise compliance and GHG projects, including air compliance assessments, permitting, dispersion modelling, stack testing, odour abatement, and noise assessments, and validation and verification of GHG emissions reporting and offset projects. Zach has worked on numerous voluntary and regulated emission offsets and compliance projects in Canada, spanning the waste, manufacturing, institutional, oil and gas, power generation, cement manufacturing, and pulp and paper sectors. Zach has completed well over 100 verification assignments in the following programs: • Alberta (oil and gas extraction, and pulp and paper); • Ontario (institutional/general, manufacturing, power generation, mining and mineral production, chemical production, and oil and gas extraction); • VCS (wind power); • ARB Cap-and-Trade Program (livestock and ODS); • CSA Clean Projects Registry (power generation); and • Québec (fuel distribution).

Verification Team

Responsibilities	All verification activities including data reviews, recalculations, and verification report preparation.
Lead Verifier-in-Training	Martha Hamre, EIT
Contact Information	mhamre@dillon.ca
Additional Qualifications	Martha is an engineering intern with four (4) years of work experience specializing in both atmospheric, infrastructure, and mining related projects, and two years of verification experience. Martha has experience quantifying emissions from both stationary and mobile sources and has performed regulatory dispersion modelling assessments to assist clients across Ontario. Martha has conducted verifications under The Climate Registry, the Greenhouse Gas Protocol, Ontario Regulation 390/18, and the Output-Based Pricing System, for facilities across Canada and the United States.
Responsibilities	All verification activities including data reviews, recalculations, and verification report preparation, and site visit.
Verifier	Alyssa Hooge, B.Sc.
Contact Information	ahooge@dillon.ca
Additional Qualifications	Alyssa is an Environmental Technologist and has a Bachelor of Technology in Environmental Engineering. Alyssa has a broad range of experience in solid waste management and environmental compliance in Canada. She has experience in GHG reporting and verification projects with Dillon for a variety client sectors, including power generation, manufacturing, oil and gas, agriculture, and waste. Through this work, she is well-versed in a number of GHG programs and protocols in Canada and the United States. She has assisted in GHG verifications under the Output-Based Pricing System, the British Columbia GHG Emission Reporting, and other Regulations.
Responsibilities	All verification activities including data reviews, recalculations, and verification report preparation.
Peer Reviewer	Jack Wallace, P.Eng., M.A.Sc.
Contact Information	jwallace@dillon.ca
Additional Qualifications	Jack is an Associate with Dillon and a licensed professional engineer in Alberta and British Columbia, and has over nine years of experience working in a variety of solid waste management and GHG projects. Jack is located in Dillon's Calgary, Alberta office and holds a range of project experience including: evaluation and design of waste processing facilities, waste management system planning and financial analysis, wastewater characterization and treatment system design, validation and verification of GHG emissions reporting and offset projects, and modelling for waste and emissions studies.
Responsibilities	Independent Peer Review activities.

Independent Reviewer Statement

By signing this Verification Report, the Independent Reviewer has reviewed the qualifications of the Verification Team and confirms that the team meets the qualification requirements found in the Regulation.

3.0 Verification Methodology

A detailed review of the verification scope and criteria, Verification Team, project understanding, timeline, and verification methodology are provided below and further detailed in the Final Verification and Sampling Plan (VSP) in **Appendix A.** This includes a detailed Sampling Plan, which describes the nature, scale, and complexity of verification activities undertaken.

3.1 Procedures

3.1.1 Conflict of Interest

Dillon performed a self-evaluation conflict of interest (COI) check to determine the potential of an actual or perceived COI that Dillon may have with the Client. The risk-based evaluation required by the Verification Criteria resulted in a low risk for COI between Dillon and the Facility/Client. The Conflict of Interest Report is included as **Appendix B and C**.

3.1.2 Project Initiation

Dillon held a kick-off conference call on February 22, 2022 to discuss verification scope; sources, sinks, and reservoirs (SSRs); and verification timelines, and to provide the Client with an initial information request. Site visit scheduling and logistics were also discussed during this meeting.

3.1.3 Verification and Sampling Plan

Dillon developed a risk-based VSP that guided the verification process. Dillon notes that this document was dynamic and did change throughout the verification process. The following was contained within the VSP:

- The verification objective, scope, and program criteria;
- The level of assurance provided, the Client's GHG assertion, and the materiality threshold;
- A description of the verification procedures (nature, timing, and extent) applied to address risks identified at the assertion level in the Facility's report;
- A qualitative narrative of the Uncertainty Risk Assessment;
- Members and roles of the Verification Team including team experience and qualifications;
- The verification schedule; and
- A dynamic Sampling Plan.

Dillon submitted an initial VSP to Newcrest on February 25, 2022. The updated VSP (including revised Sampling Plan) that is representative of the audit works undertaken, is provided in **Appendix A.**

3.1.4 Site Visit

A site visit was conducted on March 30, 2022. The site visit was conducted by Martha Hamre and included interviews with Newcrest personnel, witness of site operations and SSRs, verification of

monitoring equipment and calibration records, and a review of data collection and management procedures. Newcrest personnel who attended the site visit included Brittany Moore – Environmental Engineer-in-Training; Robert Shea – Power Generation Technician; Terry McRobb – Maintenance Planner; Gordon Everitt – Lead Waste & Potable Water Operator; Eicenober Jimenez – Waste & Potable Water Operator; Ryland Glaim – Warehouse & Freight Logistics Coordinator; and Vaughan Blackman – Environmental Scientist.

3.1.5 Independent Peer Review

An independent peer review of the Verification Report findings was performed by Jack Wallace, the Independent Peer Reviewer for the verification, on **May 26, 2022** to identify any errors in planning, data sampling, findings, and conclusions of the Verification Team. The Independent Peer Reviewer was not involved in the verification process other than by providing the independent peer review.

Upon completion of the independent review, Dillon's Independent Peer Reviewer concurred with the verification findings presented by the Verification Team.

3.2 Schedule

The verification was conducted over the schedule presented in **Table 3** below.

Table 3: Verification Schedule

Task		Timeline
0	Project award and contract signing	February 2 - 11, 2022
1	Project kick-off call	February 22, 2022
2	Initial VSP preparation and submission to Newcrest	February 25, 2022
---	Newcrest review and approval of VSP	March 7 - 11, 2022
3	Data and information exchange	March 7 - 11, 2022
4	Site visit	March 30, 2022
5	Data checks and recalculation development	March 14 - April 1, 2022
6	First round issues log submission to Newcrest	April 6, 2022
---	Newcrest review and response to issues log	April 6 – April 29, 2022
7	Second round issues log submission to Newcrest	April 29, 2022
---	Newcrest review and response to issues log	April 29 – May 24, 2022
8	Draft Verification Report preparation	April 6 – May 25, 2022
9	Independent Review	May 26, 2022
10	Submittal of Draft Verification Report to Newcrest	May 27, 2022
---	Newcrest review and response to Draft Verification Report	Within two days
11	Submittal of Final Verification Report to Newcrest and BC CAS	May 31, 2022

3.3 Risk Assessment

Dillon developed a Risk Assessment for the following aspects with respect to the Regulation:

- Facility boundary;
- Data management including acquisition equipment, sampling and frequency, and processing and tracking;
- Consistency with previous reporting periods and applied benchmarks;
- Facility production; and
- Facility GHG emissions by source (i.e., stationary combustion, mobile combustion, etc.).

Each of the above categories were developed and assessed as low, medium, or high risk, as it related to the following risk categories:

- Inherent Risk;
- Control Risk; and
- Detection Risk.

The Risk Assessment related to the above was documented in a table format within the VSP, provided in **Appendix A**.

4.0 Verification Findings

Dillon performed data checks of all supporting information and data provided by the Facility. A complete list of the documents provided to Dillon during the verification is presented in **Table B**.

The issues log was developed to summarize the data checks completed by Dillon and present any material and immaterial discrepancies that Dillon identified during verification. Any issues identified were documented in the issues log. The Facility would have an opportunity to respond to the issues identified in the issues log through verbal communication or email correspondence. The final issues log detailing all issues and their resolutions is provided in **Table C**. There were no unresolved qualitative or quantitative findings associated with the data or data management systems.

4.1 Assessment of Data Management Systems and Controls

Newcrest made available to Dillon all documentation that supported a review of the Facility Emission Report. These records include meter and raw data, operational records and logs, data management systems, quality assurance and quality control (QA/QC) practices, quantification methodologies, and staff interviews. A complete list of the documents provided to Dillon during the verification is presented in **Table B**.

The site has physical and digital data collection, and data is retained indefinitely in Newcrest's digital data management system. Data collected in physical data collection forms are digitized and stored. The source of data is acceptable for use in the Emission Report.

Dillon assessed the information systems and controls for sources of potential errors, omissions, and misrepresentations, taking into consideration the following:

- Selection and management of the GHG data and information;
- Processes for collecting, processing, consolidating, and reporting GHG data information;
- Systems and processes that ensure the accuracy of the GHG data and information;
- Degree of automation;
- Use of database features;
- Length of operation;
- Linkage to other systems;
- Standardization within an organization;
- Transparency of calculations;
- Design and maintenance of the GHG information system;
- Systems and processes that support the GHG information system; and
- Results of previous assessment.

4.2 Assessment of GHG Sources and Calculation Methodologies

Table 4 below presents Dillon's assessment of emissions data for the 2021 Submission for each SSR included in the GHG boundary and for Production. A complete list of the documents provided to Dillon during the verification is presented in **Table B**.

Table 4: Assessment of Data Findings

SSR/ Production	Verification Findings
Consistency with Previous Years	Dillon reviewed the emissions reported in 2020 and 2021 and identified a 1.3% increase in overall attributable emissions
WCI.020 – General Stationary Combustion	General stationary combustion consists primarily of backup diesel generators and propane space heaters. Additionally, solid waste materials are incinerated at the Brucejack and Knipple camp sites. Several pits are used for open burning of clean wood waste (pallets, clearing debris), with volumes estimated by dimensions logged and a default void content and density applied. The fuels combusted include: • Propane; • Diesel; • Wood waste; and • Mixed solid waste. Newcrest applied default emission factors under Part 020 of the WCI guidelines, as listed in Table 20-1 though Table 20-7, and default material property values from IPCC (2006) Volume 5: Waste for the estimation of waste emissions from incineration. Default organic and fossil carbon content values are applied based on the type of material combusted. The material breakdown of each batch incineration batch is assessed visually and logged. The methodology for waste combustion was modified from 2020 to 2021 to follow Methodology 1 of WCI.23 rather than formulas from IPCC (2006) as previously referenced. The emission factor for N_2O was revised to reference WCI Table 20-7. Based on bulk diesel delivery to the site, diesel consumption is allocated to stationary equipment based on equipment run hours, power ratings from manufacturer specifications (generator cut sheets), and default load factors. Dillon completed a recalculation of stationary combustion emissions using raw data from invoices as well as observations on the engineering estimates from the site visit and default emission factors and carbon contents (waste). Minor discrepancies were identified due to the availability of generator cut sheet information which detail fuel loads, which are not material.
WCI.280 – Mobile Equipment at Facilities	All gasoline is used for mobile equipment. Based on bulk diesel delivery to the site, and diesel consumption allocated to stationary combustion, the remainder of the diesel delivered to site is allocated to mobile equipment use. Newcrest applied default emission factors under Part 020 of the WCI guidelines, as listed in Table 20-2. Part 280 of the WCI guidelines were followed for general procedures such as sampling frequency and data management.

SSR/ Production	Verification Findings
	Dillon completed a recalculation of mobile equipment emissions using raw data from invoices and default emission factors. Minor discrepancies were identified due to generator cut sheet information referenced for General Stationary Combustion calculations, which are not material.
WCI.200 – Wastewater Emissions	Newcrest reported N_2O emissions from the aerobic wastewater treatment systems, following methodologies under Part 200 of the WCI guidelines. Total nitrogen in effluent results based on the permitted composite sample are used. Dillon completed a recalculation of wastewater emissions using raw data from total nitrogen results and wastewater flow. Minor discrepancies were identified due to wastewater volumes which are not material.
Production	Gold and silver production is tracked through the weigh data of final product using calibrated weigh scales. Weigh scales are checked with a traceable test weight before and after every recorded production weigh-in. Product is weighed prior to loading on shipment vehicles. Electricity is purchased from the grid-supplied network and invoiced monthly. Dillon reviewed electricity invoices. Dillon did not identify any discrepancies in the production reported under CIIP.

The data provided was appropriately employed by Newcrest and is deemed acceptable for quantification of the 2021 Emission Report. In addition, the emissions and production quantification methodologies referenced in the 2021 Emission Report are the same as the ones used in the baseline emissions submission.

4.3 Summary of Recalculation

Dillon performed a complete recalculation of the GHG emissions reported and production in the Facility's 2021 Emission Report and CIIP. Dillon's recalculation of GHG emissions were completed in accordance with the Verification Criteria and applicable quantification methodologies. A detailed list of Dillon's findings is presented in the Issues Log in **Table C** following the report text. The verification findings present a summary of the independent quantifications from the document review and recalculation of the GHG emissions and production reported in the Facility Inventory.
Table 5 and **Table 6** summarizes the results of Dillon's recalculated GHG emissions and production against the Facility reported regulated GHG emissions for each SSR and reported production, as well as relevant findings.

Table 5: Regulated GHG Emissions Quantification

SSR/ Production	Facility Reported Emissions	Dillon Recalculated Emissions	Difference (tonnes CO_2e)	% Difference
WCI.020 – Stationary Fuel Combustion				
Diesel	4,086	4,153	-66.55	-1.6%
Propane	3,095	3,095	0.00	0%
Wood	247	247	0.00	0%
Incineration	123	123	0.00	0%
Subtotal	7,552	7,619	-66.55	-0.88%
WCI.280 – Mobile Equipment at Facilities				
Diesel	21,324	21,258	66.55	0.3%
Gasoline	863	863	0.00	0%
Subtotal	22,187	22,121	66.55	0.30%
WCI.200 – Wastewater Emissions				
Subtotal	3.24	3.23	0.01	0.4%
Total Emissions (tonnes)	**29,743**	**29,743**	**0.01**	**0.00004%**

Table 6: Facility CIIP Production Data

Name of CIIP Product	Facility Reported Production	Dillon Recalculated Production	Difference	Difference (%)
Facility Production				
Electricity Consumption (Purchased) (GWh)	145.16	145.16	0	0%
Heat Consumption	0	0	0	0%
Tonnes of Gold Equivalent	11.124	11.124	0	0%

The accumulated evidence supports the Facility's 2021 Emission Report and CIIP assertion in terms of the required reasonable level of assurance and plus or minus 5% materiality threshold for both production and emissions separately.

5.0 Verification Statement

5.1 Statement of Verification

The Facility reported **29,743 tonnes CO_2e** of regulated emissions for the 2021 year. Dillon conducted a verification of the Newcrest 2021 Emission Report GHG assertion prepared under B.C. Reg. 249/2015 per the Verification Criteria as follows:

- *ISO 14064-1:2018 – Part 1: Specification with guidance at the organization level for quantification and reporting of GHG emissions and removals,* ISO, December 2018;
- *ISO 14064-3:2006 – Part 3: Specification with guidance for the validation and verification of GHG assertions,* ISO, March 2006;
- SBC 2014, *Chapter 29: Greenhouse Gas Industrial Reporting and Control Act*, current to January 20, 2021;
- BC Regulation 249/2015: *Greenhouse Gas Industrial Reporting Regulation: Greenhouse Gas Emission Reporting Regulation (Regulation), as amended by BC Reg. 294/2020*, February 2021.
- B.C. Regulation 231/2019: *Greenhouse Gas Industrial Reporting and Control Act*;
- Western Climate Initiative (WCI) *Final Essential Requirements of Mandatory Reporting: Amended for Canadian Harmonization*, December 17, 2010;
- WCI *2011 Amendments for Harmonization of Reporting in Canadian Jurisdictions*, December 21, 2011;
- WCI *Quantification Method 2013 Addendum to Canadian Harmonization version*, December 10, 2013; and,
- CleanBC Industrial Incentive Program Guideline (CIIP)

Based on the procedures undertaken, it is our opinion that:

- The assertions in the Newcrest 2021 Emission Report prepared under the BC Greenhouse Gas Emission Reporting Regulation (BC Reg. 249/2015) are materially correct and are a fair and accurate representation of the Facility's total attributable emissions for the 2021 reporting period; and
- The Newcrest 2021 Emission Report was prepared and the emissions reported in it quantified in accordance with the Regulation.

A completed Emissions Report Verification Statement, as required by CAS and based on the template provided, is included as **Appendix B**.

5.2 Limitation of Liability

This report and statement was prepared exclusively for the purposes, project, and site locations outlined in the report and statement. The report is based on information provided to, or obtained by Dillon Consulting Limited ("Dillon") as indicated in the report, and applies solely to site conditions existing at the time of the site investigation(s). Although a reasonable level of assurance investigation was

conducted by Dillon, Dillon's investigation was by no means exhaustive. Rather, Dillon's report represents a reasonable review of available information within an agreed work scope, schedule, and budget. Further review and updating of the report may be required as conditions and the regulatory and planning frameworks, change over time.

This report was prepared by Dillon for the sole benefit of our Client. The material in it reflects Dillon's best judgment in light of the information available to it at the time of preparation. Any use which a third party makes of this report, or any reliance on or decisions made based on it, are the responsibilities of such third parties. Dillon accepts no responsibility for damages, if any, suffered by any third party as a result of decisions made or actions based on this report.

The information and opinions rendered in this report are exclusively for use by Newcrest. Dillon will not distribute or publish this report without Newcrest's consent except as required by law or court order. The information and opinions expressed in this report are given in response to a limited assignment and should only be evaluated and implemented in connection with that assignment. Dillon accepts responsibility for the competent performance of its duties in executing the assignment and preparing this report in accordance with the normal standards of the profession, but disclaims any responsibility for consequential damages.

The work completed for this verification was completed as part of the legally enforceable contract for GHG assurance services. The associated reports and statements provided to Newcrest as part of the assurance services provided, are intended for the use of Newcrest and the BC Ministry of Environment Climate Action Secretariat as the regulator only. Should Newcrest wish to use Statements or Marks provided throughout this process, they must seek do so via written statement.

6.0 Conflict of Interest Report

The Conflict of Interest Report, as required by the Regulation, is included as **Appendix B**.

Final Issues Log

Issue No.	Type	Date	Issue Detail	Client Response V1	Status	Client Response V2	Status
1	CL	17-Mar-22	File: 2021 Open Pit Burn log Please clarify for months with multiple burn dates, whether the provided volume burned corresponds to monthly total, or burn volume per event	Where multiple burns occurred during a month, volumes were added up to give a total volume for that month. KU 12/4	Closed		
2	DR	17-Mar-22	File: 11. Novmber 2021 Incinerator BJ log File appears to be a duplicate of the October 2021 data. Please provide November 2021 Incinerator BJ log	Please find November, now updated, in the sharefile. 14/3 KU	Closed		
3	CL	28-Mar-22	File: PVG_Stationary Diesel_2021 Bowser stationary diesel usage is calculated at 50% load instead of 75% of load. Please clarify reason for change from other camps.	The generator at Bowser is rarely used and when it is, it has far more power than required for the area it supplies. Hence the load on it is less than the standard 75%. Talked to Jarret and he explained over email too.	Discussed during site visit. Closed.		
4	CL	28-Mar-22	File: PVG_Stationary Diesel_2021 Location - Stuart appears to be excluded from totals. Please clarify reason for exclusion, or include.	Now included. KU 16/4	Closed		
5	OB	28-Mar-22	File: PVG_Stationary Diesel_2021 Dillon recalculated with a volume conversion factor of 3.78541 Litres per Gallon, which results in a non-material discrepancy	Acknowledged. We understand. We can improve for next year by following spec sheet consumption, which is preffered.	Closed		
6	DR	28-Mar-22	Please provide generator cut sheets to verify fuel consumption ratings	Have upoaded what we have. Acknowledge that is good to have for next year. We will upload more as they come.	Dillon identified that data in cut sheets does not align with information in the *2021 Hours and Kilometers* workbook. Significant difference in GEN-022 and GEN-007 through GEN-012 Please review and confirm data source for provided fuel consumption ratings.	Updated fuel consumption values in *PVG_Stationary Diesel_2021_v2* spreadsheet to match rates in cut sheets. Uploaded cut sheet for GEN-007 through GEN-012 (rates differ from Google search screenshot values). Also uploaded cut sheet for GEN-031. Updated total values in workbook *22.05.06_GHG Worksheet_2021* . (BM / 05-May-22)	Closed
7	DR	28-Mar-22	Please include production data, including purchased heat and electricity, in accordance with CIIP documentation: https://www2.gov.bc.ca/assets/gov/environment/climate-change/ind/cleanbc-program-for-industry/guidance/metal_ore_mining_sector_guidance.pdf	Uploaded 13/4 KU	Please provide production data and completed metal_ore_mining_calculator_2021.xlsx workbook from CleanBC Purchased electricity records provided, closed.	Final production values from Mine Site Controller provided. (KU-17-May-22)	Closed
8	DR	28-Mar-22	Please provide production weigh scale calibration records	Need to ask	Data pending	As per email *RE_Production Scales - Calibration* there are no calibration records for the dore weighing scale. A 20kg traceable test weight is used to check the scale reading before and after packing a dore shipment. (BM / 05-May-22)	Closed
9	OB	25-Mar-22	File: GHG Worksheet_2021 Minor discrepancies are noted in the total food and domestic waste incineration for Brucejack. Please review data provided and confirm sums of waste incinerated align with the Brucejack Incinerator Log data.	Discrepancies should be rectified now. KU 15/4	Closed		
10	OB	25-Mar-22	File: GHG Worksheet_2021 Include "Kitchen Grease/Oils" in Waste Incinerator summary for Brucejack	Included. All waste numbers should be up to date. 15/4 KU	Closed		
11	DR	25-Mar-22	Please provide reference data for 2021 Total Volume Effluent Processed, by month	If you look in the STP > STP effluent volumes > see the report C75. Volumes are recorded in those spreadsheets.	Closed		
12	CL	25-Mar-22	File: GHG Worksheet_2021; Mobile Gas tab Please confirm GWP referenced to calculated CO2e emission factor (2.379)	Resolved. Calculation has been adjusted.	Open: Please review conversion from kg to tonnes. In Totals tab, please complete mobile gasoline CO2e emissions in kg	Updated conversion factor to be tonnes = kg/1000. Added gasoline CO2e emissions in kg to Totals tab.(BM / 06-May-22)	Closed
13	DR	28-Mar-22	Please provide supporting invoices/records for propane deliveries	Additionals have been added to stationary propane folder.	Supporting invoices and records do not comprehensively support propane deliveries. Please review and adjust accordingly.	Previous missing invoices were downloaded from JD Edwards and uploaded to Dillon file share site. (BM / 06-May-2022)	Closed
14	CL	17-Mar-22	File: GHG Worksheet_2021 Please confirm data source for wood waste (open burn) emission factors	https://www2.gov.bc.ca/assets/gov/environment/climate-change/ind/quantification/wci-2012.pdf	Open: Please review CO2e emission factor applied (0.02)	Rather than applying a separate emission factor to calculate the quanitiy of CO2e, I summed the CO2, CH4 and N2O emissons. I applied this method to all emissions sources. (BM / 06-May-2022)	Closed
15	DR	28-Mar-22	File: GHG Worksheet_2021 Please include calculations and results for biogenic CO2 (see GHG Worksheet_2020.xlsx as example)	Resolved. Now included.	Open. Dillon identified that the totals tab does not differentiate non-biogenic and biogenic emissions. Please adjust accordingly.	Updated. (BM / 07-May-22)	Closed
16	CL	28-Mar-22	File: 3134778 - pretium volumes 2021 -summer Please confirm the inclusion of the October 6, 2021 transaction NW65876CR (-2,886.00), and provide invoice backup	Mobile diesel and Gas > Pretium volumes 2021 - summer . Line 244 has all deliveries. BOL has now been included also. See Northwest receipts	Closed		
17	OB	28-Mar-22	File: GHG Worksheet_2021 Wastewater nitrogen data references composite sample results. Dillon recalculated using highest effluent nitrogen value, which results in a non-material discrepancy	Discussed during site visit. We use composite effluent for permit. Resolved	Closed		

Issue No.	Type	Date	Issue Detail	Client Response V1	Status	Client Response V2	Status
18	OB	28-Mar-22	File: GHG Worksheet_2021 Please include wastewater and incineration activities in total site emissions calculation	Updated.	Open. In Totals tab: - Dillon identified that the Stationary incineration did not include CH4 and N2O. Please adjust accordingly. In Waste Incineration tab: - Please confirm data source for 60 g N2O/t MSW	Added CH4 and N2O emissions for stationary incineration.Updated all calculations to follow Methodology 1 of WCI.23 rather than formulas from 2006 IPCC Guidelines for National GHG Inventories. Updated emisison factor for N2O emissions from MSW obtained from WCI.23 Table 20-7. (BM / 07-May-22)	Closed
19	CL	13-Apr-22	Confirm if accelerants are used in the burn pit	No. A blow torch is used to start the burn.	Closed		
20	CL	14-Apr-22	What is the size of the burn pit	25' x 25'	Closed		
21	DR	14-Apr-22	Include serial numbers of the generators	They have been added to the PVG_Stationary_Diesel excel file	Closed		
22	DR	14-Apr-22	Include example of daily/weekly generator checks/inspections	Uploaded to stationary diesel folder 14/4 KU	Closed

Risk-Based Verification and Sampling Plan
Greenhouse Gas Emission Reporting Regulation – B.C. Regulation 249/2015 – ANAB Accreditation under ISO 14065
2021 Emission Report for the Newcrest Brucejack Gold Mine Facility

Introduction

Dillon Consulting Limited (Dillon) is pleased to present Newcrest Mining Limited (Newcrest; formerly Pretium Exploration Inc.) with this risk-based Verification and Sampling Plan under British Columbia Greenhouse Gas Emission Reporting Regulation (B.C. Reg. 249/2015 [the Regulation]) under the *Greenhouse Gas Industrial Reporting and Control Act* for the Newcrest Brucejack Gold Mine Facility, located north of Stewart, British Columbia, Canada (Facility or Site). The Facility is registered with the BC Ministry of Environment (MOE) and Climate Change Strategy with BCGHG ID # 22122200002.

The Facility is using quantification methodologies developed in consideration of British Columbia Greenhouse Gas Emission Reporting Regulation (Regulation), CleanBC Industrial Incentive Program (CIIP) and the Western Climate Initiative (WCI) *Final Essential Requirements of Mandatory Reporting: Amended for Canadian Harmonization* (2011).

Verification Objectives

The objectives of this assignment were to provide Newcrest and BC MOE Climate Action Secretariat (CAS) (the Regulator) with a reasonable level of assurance, independent, third party verification, and opinion on whether the Facility's 2021 Emission Report and Production under the CleanBC Industrial Incentive Program (CIIP) are free of material misstatements, as well as that the information reported is accurate and consistent with the requirements of the Regulation and CIIP.

Verification Scope

The following is a summary from the 2021 Project Report for the Project.

Time Period – January 1, 2021 through December 31, 2021

Geographic and Organizational Boundaries: This scope includes the production and emissions generated at the Facility at the physical address as listed below. The emissions are related to specific GHG activities listed in the Regulation and emitted by the Facility. The Facility is located at the following address:

Approximately 65 km north of Stewart
Regional District of Kitimat-Stikine, British Columbia
Coordinates: 56°27'55.94"N, 130°11'10.06"W

Activities and Processes: The Facility is an underground high-grade gold mine. The operations and camps are connected to the BC Hydro power grid with full diesel backup generation capacity. The Facility includes three active camp sites, and one closed camp site: Wildfire Camp, Knipple Camp, Brucejack Camp, and Bowser Camp (closed). Operations on-site include:

- WCI.280 – Mobile Equipment at Facilities:
  - Diesel in heavy equipment; and
  - Gasoline in off-road mobile equipment;
- WCI.020 – General Stationary Combustion:
  - Diesel in backup generators;
  - Propane in space heaters;
  - Waste materials in incinerator; and
  - Open burning of wood waste; and
- Wastewater treatment on-site.

GHG Emission Sources, Categories, and GHG Types: Based on Dillon's current understanding of Facility operations, the applicable Facility emission sources and gases are marked with a "Y" in the appended **Table A.** For completeness, the emission sources and gases that are not applicable to the Facility are marked with an "N/A", and sources and gases that are negligible are marked with an "NEG".

Verification Criteria

Dillon completed the verification based on and including the following criteria:

- *ISO 14064-1:2018 – Part 1: Specification with guidance at the organization level for quantification and reporting of GHG emissions and removals,* ISO, December 2018;
- *ISO 14064-3:2006 – Part 3: Specification with guidance for the validation and verification of GHG assertions*, ISO, March 2006;
- SBC 2014, Chapter 29: *Greenhouse Gas Industrial Reporting and Control Act*
- B.C. Regulation 231/2019: *Greenhouse Gas Industrial Reporting and Control Act*;

- BC Regulation 249/2015: *Greenhouse Gas Industrial Reporting Regulation: Greenhouse Gas Emission Reporting Regulation* (Regulation), as amended by BC Reg. 294/2020, February 2021;
- Western Climate Initiative (WCI) *Final Essential Requirements of Mandatory Reporting: Amended for Canadian Harmonization,* December 17, 2010;
- WCI *2011 Amendments for Harmonization of Reporting in Canadian Jurisdictions,* December 21, 2011;
- WCI *Quantification Method 2013 Addendum to Canadian Harmonization version,* December 10, 2013; and,
- CleanBC Industrial Incentive Program Guideline (CIIP)

Level of Assurance and Materiality

The verification was conducted to a reasonable level of assurance, per the requirements of the Regulation and CIIP.

The materiality threshold for the Facility was set at plus or minus 5% of the reported 2021 emissions. Dillon understands that the Facility also reported their production under the CleanBC Industrial Incentive Program (CIIP) and the materiality was set at 5% of the 2021 production.

BC Regulation requires that net of all over or understatements cannot exceed the lesser of 1,000 tonnes of CO_2e or 1% of the total emissions. In addition, CIIP requires that all correctable errors be corrected and that the aggregate effects of error results in any inaccuracy be no greater than 0.1%.

Verification Procedures

Dillon used a risk-based verification methodology consistent with the requirements of the Regulation and CIIP. The following subsections detail Dillon's verification procedures for the document and data reviews, and the contents of the Sampling Plan and Risk Assessment.

Kick-Off Meeting

The kick-off meeting was hosted via teleconference following the award of the work by Newcrest to Dillon and the finalization of the verification contract. The meeting covered the following key items:

- Review of roles and responsibilities;
- Review of schedule;
- Review of the audit process to be implemented by Dillon;
- Resolution of any questions; and
- Site Visit and Health and Safety Requirements.

Document and Data Reviews

Dillon completed the verification process using the following fundamental practices:

- Assessment of GHG information systems and controls;
- Assessment of GHG data and information; and
- Assessment against validation or verification criteria.

Upon acceptance of the Verification/Sampling Plan, Dillon submitted an initial information and data request. This request consisted of:

- The Facility's 2021 Emission Report;
- The Facility's CIIP Application;
- Inventory and stock records for production;
- Onsite and offsite delivery records;
- Purchase and delivery records for inputs;
- Previous quantification and verification reports (as applicable);
- Application or project report and any other submission documents;
- Process flow diagrams;
- Third party fuel consumption invoicing;
- Internal metering data;
- Calibration certificates and maintenance schedule for internal meters;
- Quantification details;
- Calculations/spreadsheets used to create the reports; and
- Other materials/sources that were used to support the 2021 Emission Report.

Assessment of Data Management Systems and Internal Controls

Dillon assessed the information systems and controls for sources of potential errors, omissions, and misrepresentations, taking into consideration the following:

- Selection and management of the GHG data and information;
- Processes for collecting, processing, consolidating, and reporting GHG data information;
- Systems and processes that ensure the accuracy of the GHG data and information;
- Degree of automation;
- Use of database features;
- Length of operation;
- Linkage to other systems;
- Standardization within an organization;
- Transparency of calculations;

- Design and maintenance of the GHG information system;
- Systems and processes that support the GHG information system; and
- Results of previous assessment, if available and appropriate.

Assessment of Data and Information Flow

In parallel to the assessment of data management systems and internal controls, Dillon also examined and assessed the data and information flows that formed the basis for Newcrest's GHG assertion with professional skepticism. This assessment was informed by the Verification/Sampling Plan, and like the Verification/Sampling Plan, the assessment of data and information flow was a dynamic and changing process. The Verification Team reviewed sufficient data and information sources to complete the verification in accordance with the Regulation. Accordingly, the Verification/Sampling Plan contains the following requirements, as applicable to the assignment:

- Where possible, review full data sets. When full data sets were not feasible, the Designated Signing Authority determined based on magnitude and accuracy, to what degree (or confidence interval) the data and information was reviewed;
- Review of collection frequency and retention period;
- Complete a rank-based Risk Assessment for each source including the risks related to data and information sources, along with items such as metering, third party data, and self-calculation;
- Focus on data and information sources that may result in a material misstatement; and
- Quality assurance and quality control of the data sets.

Where information or data was either not supplied by Newcrest or was determined to be insufficient, the Verification Team requested additional data and/or information.

Site Visit

Dillon visited the Facility on March 30, 2022 as agreed upon during the kick-off meeting (and subsequent communications) as required by B.C. Reg. 249/2015 subsection (2) (d) and the CIIP verification requirements. The purpose of the site visit was to interview Newcrest personnel, witness site operations, production parameters and GHG emissions sources, verify monitoring equipment and calibration records, as well as review data collection and management procedures.

Uncertainty and Risk Assessment

Dillon developed a Risk Assessment for the following aspects with respect to the Regulation:

- Facility boundary;
- Data management including acquisition equipment, sampling and frequency, and processing and tracking;

- Consistency with previous reporting periods and applied benchmarks;
- Facility production; and
- Facility GHG emissions by source (i.e., stationary combustion, mobile combustion, etc.).

Each of the above categories were developed and assessed as low, medium, or high risk, as it related to the following risk categories:

- Inherent Risk;
- Control Risk; and
- Detection Risk.

The Risk Assessment related to the above were documented in a table format within the Verification/Sampling Plan and Verification Report, respectively. The Risk Assessment is appended in **Table B**.

Working Papers

Throughout the verification process, the Verification Team developed a set of working papers that outline the information reviewed, re-calculation of data sets as applicable, and issues developed by Dillon and their subsequent resolution status. The working papers do not form part of the Final Verification Report, but the information contained within them contributed to the Verification Statement issued by Dillon.

Issues Log

Throughout the verification process, the Verification Team developed a list of verification findings in an issues log, representing clarifications and corrective actions for Newcrest to respond to. The issues logs were be based on the results of Dillon's independent recalculations of Newcrest's GHG assertion, as well our assessment of data management, controls, and data flow. Upon closure, the verification proceeded to the independent peer review and reporting stages.

Independent Review

As a final step of verification, Dillon conducted an independent review of the verification. The independent review included a review of the working papers developed by the Verification Team and the Draft/Final Verification Report and Statement prepared by the team. Dillon notes that the Final Verification Report and Statement were not finalized until approval was received from the Independent Reviewer.

Verification Report and Statement

At the conclusion of the verification process, Dillon prepared a Draft Verification Report that was be subject to internal peer review, as well as review by Newcrest. The Verification Report was be prepared utilizing the appropriate Verification

Statement and Conflict of Interest Report Form as detailed in the Regulation and was prepared by the Lead Verifier.

The Conflict of Interest Report, as set out in the Regulation, includes:

- An assessment of threats to independence;
- Strategies for mitigating threats to independence; and
- A report on the implementation of the strategies referred to above.

The Verification Report and Statement includes:

- Statement of Verification completed in accordance with the Regulation;
- Identification of the following:
  - Information in the emission report that was not reported or quantified in accordance with the Regulation but was corrected during the verification process;
  - Information in the emission report that was not reported or quantified in accordance with the Regulation and was not corrected during the verification process; and
  - The materiality of any errors, omissions, or misstatements in the emission report;
- The name and business address of the Verification Body;
- The name, business email address, and business telephone number of the Lead Verifier;
- The name, business email address, and business telephone number of the Verifiers who assisted the Lead Verifier in performing the verification;
- With respect to the reporting operation, the information referred to in Section 14 (2) of the Regulation;
- With respect to a linear facilities operation, identification of each individual Facility of the reporting operation that has attributable emissions in the reporting period that are:
  - Greater than or equal to 10,000 tonnes of carbon dioxide equivalent, not including carbon dioxide produced from biomass listed in Schedule C;
  - Greater than or equal to 1,000 tonnes and less than 10,000 tonnes of carbon dioxide equivalent, not including carbon dioxide produced from biomass listed in Schedule C; or
  - Less than 1,000 tonnes of carbon dioxide equivalent, not including carbon dioxide produced from biomass listed in Schedule C;
- The date the Verification Statement was completed;
- The scope of the Verification Statement, including whether it relates to all the matters required to be verified under Section 28 of the Regulation;

- The amount referred to in Section 14(3)(a) of the Regulation, with subtotals setting out the total amounts of:
  - Carbon dioxide from non-biomass;
  - Carbon dioxide from biomass listed in Schedule C of the Regulation; and
  - Carbon dioxide from biomass not listed in Section C;
- The name of the member of the International Accreditation Forum by which the verification body is accredited and any associated identification numbers, accompanied by the affirmation of the International Accreditation Forum that the accreditation status is in good standing;
- A summary of the work the verification body performed as part of the verification, including a description of:
  - The verification procedures used to test the data included in the emission report prepared by the reporting operation; and
  - Additional information, not included in the emission report, that was directly or indirectly relied on by the verification body in the course of conducting the verification;
- Identification of each site visit made in the verification and the date the site visit was conducted;
- Identification of (CIIP only):
  - Errors, omissions, and misstatements related to the reported product data that were corrected as part of the verification process
  - Errors, omissions, and misstatements related to the reported product data that were not corrected as part of the verification process, and;
  - The materiality of any errors, omissions, and misstatements related to the reported product data included in the CIIP application.
- A signed declaration by the Lead Verifier on behalf of the verification body that:
  - The Lead Verifier represents an accredited verification body;
  - The evidence obtained during the verification is sufficient and appropriate to support the verification opinion;
  - The Verification Statement is true, accurate and complete; and
  - The verification work documented in the statement was performed in accordance with the Regulation and CIIP;
- A signed declaration from an Independent Peer Reviewer that:
  - The Independent Peer Reviewer was not involved in the verification documented in the Verification Statement, other than by providing an independent peer review; and
  - The verification used to produce the Verification Statement was appropriate;
- A conflict of interest report; and
- Any other information required by the Regulation and CIIP.

Verification Team

For this assignment, Dillon assembled an experienced Verification Team consisting of the following individuals.

Lead Verifier and Technical Expert – Zachary Zehr, P.Eng.

Zach is a licensed professional engineer in Ontario, and has a Bachelor of Engineering in Environmental Engineering from the University of Guelph. Zach has more than eight (8) years of experience working in a variety of air and noise compliance and GHG projects, including air compliance assessments, permitting, dispersion modelling, stack testing, odour abatement, and noise assessments, and validation and verification of GHG emissions reporting and offset projects.

Zach has worked on numerous voluntary and regulated emission offsets and compliance projects in Canada, spanning the waste, manufacturing, institutional, oil and gas, power generation, cement manufacturing, and pulp and paper sectors. Zach has completed well over 100 verification assignments in the following programs:

- Alberta (oil and gas extraction, and pulp and paper);
- Ontario (institutional/general, manufacturing, power generation, mining and mineral production, chemical production, and oil and gas extraction);
- VCS (wind power);
- ARB Cap-and-Trade Program (livestock and ODS);
- CSA Clean Projects Registry (power generation); and
- Québec (fuel distribution).

Lead Verifier-in-Training – Martha Hamre, EIT

Martha is an engineering intern with four (4) years of work experience specializing in both atmospheric, infrastructure, and mining related projects, and two years of verification experience. Martha has experience quantifying emissions from both stationary and mobile sources and has performed regulatory dispersion modelling assessments to assist clients across Ontario. Martha has conducted verifications under The Climate Registry, the Greenhouse Gas Protocol, Ontario Regulation 390/18, and the Output-Based Pricing System, for facilities across Canada and the United States.

Verifier – Alyssa Hooge, B.Sc.

Alyssa is an Environmental Technologist and has a Bachelor of Technology in Environmental Engineering. Alyssa has a broad range of experience in solid waste management and environmental compliance in Canada. She has experience in GHG reporting and verification projects with Dillon for a variety client sectors, including power generation, manufacturing, oil and gas, agriculture, and waste. Through this work, she is well-versed in a number of GHG programs and protocols in Canada and

the United States. She has assisted in GHG verifications under the Output-Based Pricing System, the British Columbia GHG Emission Reporting, and other Regulations.

Peer Reviewer – Jack Wallace, P.Eng., M.A.Sc.

Jack is an Associate with Dillon and a licensed professional engineer in Alberta and British Columbia, and has over nine years of experience working in a variety of solid waste management and GHG projects. Jack is located in Dillon's Calgary, Alberta office and holds a range of project experience including: evaluation and design of waste processing facilities, waste management system planning and financial analysis, wastewater characterization and treatment system design, validation and verification of GHG emissions reporting and offset projects, and modelling for waste and emissions studies.

Jack has extensive experience in a wide range of GHG projects including sectoral scopes ranging from but not limited to: renewable power generation (wind, geothermal, and hydroelectric), oil and gas, agricultural, manufacturing, institutional, chemical plants, pulp and paper facilities, and landfill gas/biogas combustion plants. These projects have been conducted under numerous GHG programs including: California Air Resources Board (ARB) Cap-and-Trade Compliance Offset Program, Verified Carbon Standard (VCS), Canadian Standards Association (CSA) CleanProjects, The Climate Registry, Gold Standard, and the Alberta, British Columbia, and Ontario Reporting and Offset Programs.

Jack has completed well over 50 validation or verification assignments in the following programs:

- British Columbia (institutional/general, oil and gas extraction, pulp and paper, waste, landfill);
- Alberta (oil and gas extraction, composting, landfill, chemical, biogas plants, pulp and paper, food processing);
- Ontario (institutional/general, manufacturing, power generation, mining and mineral production, chemical production, waste);
- VCS (wind power and landfill/waste);
- ARB Cap-and-Trade Program (livestock and ozone depleting substances [ODS]);
- CSA Clean Projects Registry (composting, energy efficiency, electrification, fuel switching);
- United Nations Framework Convention on Climate Change (UNFCCC) Clean Development Mechanism (CDM) (landfill, wind power, hydroelectric, ODS, solar); and
- The Climate Registry (manufacturing, power generation, electric power transactions).

Uncertainty Risk Assessment and Sampling Plan

Based upon available information at the onset of the verification process, Dillon developed a Qualitative Narrative of the Uncertainty Risk Assessment, presented as **Table B** (attached).

In compliment to the Risk Assessment, Dillon developed a Sampling Plan as presented in **Table C** (attached).

Final versions of both **Table B** and **Table C** are provided with the final Verification Report.

Use of Statements and Marks

This Verification and Sampling Plan is part of the legally enforceable contract for GHG assurance services. This Verification and Sampling Plan, and associated reports and statements provided to Newcrest as part of the assurance services provided, are intended for the use of Newcrest and the BC CAS as the regulator only. Should Newcrest wish to use Statements or Marks provided throughout this process, they must seek to do so via a written statement.

Verification Schedule

Dillon provided assurance services consistent with the tasks and schedule presented in **Table 1** below. Dillon is aware of the BC CAS reporting deadline of May 31, 2022 for verified 2021 emissions.

Table 1: Scope of Work Tasks and Schedule

Task		Timeline
0	Project award and contract signing	February 2 - 11, 2022
1	Project kick-off call	February 22, 2022
2	Initial VSP preparation and submission to Newcrest	February 25, 2022
---	Newcrest review and approval of VSP	March 7 - 11, 2022
3	Data and information exchange	March 7 - 11, 2022
4	Site visit	March 30, 2022
5	Data checks and recalculation development	March 14 - April 1, 2022
6	First round issues log submission to Newcrest	April 6, 2022
---	Newcrest review and response to issues log	April 6 – April 29, 2022
7	Second round issues log submission to Newcrest	April 29, 2022
---	Newcrest review and response to issues log	April 29 – May 24, 2022
8	Draft Verification Report preparation	April 6 – May 25, 2022
9	Independent Review	May 26, 2022
10	Submittal of Draft Verification Report to Newcrest	May 27, 2022
---	Newcrest review and response to Draft Verification Report	Within two days
11	Submittal of Final Verification Report to Newcrest and BC CAS	May 31, 2022

Closure

Please do not hesitate to contact Zachary Zehr at 226-752-9319 or zzehr@dillon.ca should you have any questions.

Sincerely,

DILLON CONSULTING LIMITED

Zachary Zehr, P.Eng

Appendix B

Qualitative Narrative – Uncertainty Risk Assessment

Table B
Newcrest Mining Limited - Brucejack Gold Mine Facility
Verification and Sampling Plan

Qualitative Narrative - Uncertainty Risk Assessment

SSR	GHG Source / Risk Factor	Percentage of Emissions	Risk Type	Risk Level	Risk Action
General					
---	Facility Boundary	N/A	Inherent	Low	Low risk action, facility boundaries are well defined and include operations that largely do not change year to year.
			Control	Low	
			Detection	Low	
---	Data Management Systems	N/A	Inherent	Low	The detection and control risks for data management systems can be classified as a medium risk, as there may be instances when transcription errors and double counting may occur. Instances where emissions calculations software is not updated or checked automatically may also exist. As a whole, the risk of errors with the data management system were medium to low.
			Control	Medium	
			Detection	Medium	
---	Consistency with Baseline	N/A	Inherent	Low	The detection risk for emissions changes and consistency with previous years can be classified as a medium risk, as there may be instances when transcription errors may occur. As a whole the risk of errors due to inconsistencies with previous years were low.
			Control	Low	
			Detection	Medium	
---	Production	N/A	Inherent	Medium	The inherent and control risk has been set to medium as the process of collecting data for these production sources can be complex and require multiple departments and sources. There is also a risk of allocation and omitting production data. Detection risk has been set to low as Dillon reviewed the data which was made available.
			Control	Medium	
			Detection	Low	
Emission Sources					
1	WCI.020 - General Stationary Combustion (Diesel)	13.74%	Inherent	Medium	Significant source for reporting with resulting high inherent risk. Third party invoices for fuel consumption may lead to accounting errors, and allocation across stationary vs. mobile sources may lead to reporting errors, both resulting in medium control risk. All invoices were reviewed and assessed with trending and equipment inventory to reduce inherent and control risks, resulting in a lower detection risk.
			Control	Medium	
			Detection	Low	
2	WCI.020 - General Stationary Combustion (Propane)	10.41%	Inherent	Low	Smaller scale source when compared with diesel, resulting in low inherent risk. Understood to make use of third party invoices, resulting in medium detection risk. Detection risk was set to medium given low inherent risk.
			Control	Medium	
			Detection	Medium	
3	WCI.020 - General Stationary Combustion (Mixed Waste)	0.41%	Inherent	Low	Minor source, resulting in low inherent risk. Understood to be estimated on-site based on mass quantities or loads, increasing control risk. Detection risk was set to medium given low inherent risk.
			Control	High	
			Detection	Medium	
4	WCI.020 - General Stationary Combustion (Wood Waste)	0.83%	Inherent	Low	Minor source, resulting in low inherent risk. Understood to be estimated on-site based on mass quantities or loads, increasing control risk. Detection risk was set to medium given low inherent risk.
			Control	High	
			Detection	Medium	
5	WCI.280 - Mobile Equipment at Facilities (Diesel)	71.70%	Inherent	Medium	Significant source for reporting with resulting higher inherent risk. Third party invoices for fuel consumption may lead to accounting errors, and allocation across stationary vs. mobile sources may lead to reporting errors, both resulting in medium control risk. All invoices were reviewed and assessed with trending and equipment inventory to reduce inherent and control risks, resulting in a lower detection risk.
			Control	Medium	
			Detection	Low	
6	WCI.280 - Mobile Equipment at Facilities (Gasoline)	2.90%	Inherent	Medium	Minor source for reporting with resulting medium inherent risk. Third party invoices for fuel consumption may lead to accounting errors, and allocation across stationary vs. mobile sources may lead to reporting errors, both resulting in medium control risk. All provided invoices were reviewed and assessed with trending and equipment inventory to reduce inherent and control risks, resulting in a lower detection risk.
			Control	Medium	
			Detection	Low	
7	WCI.200 - Wastewater Emissions	0.01%	Inherent	Low	Minor source, resulting in low inherant risk. Wastewater volumes measured and collected by Newcrest. Operations were observed to minimize risk detection and control risks.
			Control	Low	
			Detection	Low

Sampling Plan

Table C
Newcrest Mining Limited - Brucejack Gold Mine Facility
Verification and Sampling Plan

Sampling Plan

SSR	GHG Source	Percentage of Emissions	Data Check and Document Review Methods	Data Sources / Parameters	Monitoring Schedule	Sampling Action
General						
---	Facility Boundary	N/A	• Reviewed historical reporting and Site Visit to assess boundary. • Interviewed key Facility and head office staff	• Process flow diagram(s) • Emissions report(s) • Site visit	Once at Start	• Reviewed the past emissions report for consistency with current year. • Interviewed Facility staff.
---	Data Management Systems	N/A	• Reviewed Data Management Systems and their interactions with staff and each other • Reviewed meter calibrations and tracking of work orders	• Data historian, management systems • Operational records, staff logs • Calibration and inspection records and reports • Quality Assurance/Quality Control (QA/QC) procedures • Staff interviews	As recorded or annualy	• Reviewed the Facility's data systems including frequency of data collection. • Interviewed Facility staff. • Reviewed calibration records and maintenance logs for meters and equipment.
---	Consistency with previous years	N/A	• Reviewed regulatory and Programme changes, updated guidelines and standards, and quantification methods • Reviewed quantification methodology applied	• Quantification methodology document (QMD) or similar • Regulation, Programme documents, standards, and guidelines	Once at Start	• Reviewed the past emissions report for consistency with current year.
---	Electricity purchased	N/A	• Reviewed regulatory and Programme changes, updated guidelines and standards • Reviewed Production requirements	• Data historian, management systems. • Operational records, staff logs. • Calibration and inspection records and reports. • Electricity meter data • Staff interviews.	As recorded or annually	• Reviewed the Facility's data systems including frequency of data collection. • Interviewed Facility staff. • Reviewed production data collection system
---	Heat Purchased	N/A	• Reviewed regulatory and Programme changes, updated guidelines and standards • Reviewed Production requirements	• Data historian, management systems. • Operational records, staff logs. • Calibration and inspection records and reports. • Steam and Heat Production • Staff interviews.	As recorded or annually	• Reviewed the Facility's data systems including frequency of data collection. • Interviewed Facility staff. • Reviewed calibration records and production data collection system
---	Total Gold production	N/A	• Reviewed regulatory and Programme changes, updated guidelines and standards, and quantification methods. • Reviewed quantification methodology applied. • Reviewed Production requirements	• Data historian, management systems. • Operational records, staff logs. • Calibration and inspection records and reports. • Weigh scales and production tracking system • Staff interviews.	As recorded or annually	• Reviewed production values and management of data • Review calibration records • Interviewed Facility staff
---	Total Silver Production	N/A	• Review regulatory and Programme changes, updated guidelines and standards, and quantification methods. • Review quantification methodology applied • Review Production requirements	• Data historian, management systems. • Operational records, staff logs. • Calibration and inspection records and reports. • Weigh scales and production tracking system • Staff interviews.	As recorded or annually	• Review past production reports and sale records. • Review production values and management of data • Review calibration records and maintenance logs for meters and equipment. • Review the Facility's data systems including frequency of data collection. • Interview Facility staff.
Emission Sources						
1	WCI.020 - General Stationary Combustion (Diesel)	13.74%	• Raw and metered data. • Full recalculation of emissions. • Reviewed data assumptions and methods. • Reviewed consistency to regulatory defaults, emission factors, and calculation methodologies. • Reviewed regulatory compliance. • Operational status of equipment.	• Calculation workbooks. • Invoiced data (third party invoices, heating values, carbon content). • Metered data (flow rates, steam generation). • Calibration records and operations logs. • Regulatory parameters. • Heating equipment inventory.	As recorded or monthly	• Invoiced quantities. • Engineering estimates and assumptions. • Default factors from regulatory documents. • Review methodology for stationary emissions estimations. • Review equipment list and operating data. • Review allocation methods for stationary vs. mobile equipment.
2	WCI.020 - General Stationary Combustion (Propane)	10.41%				
3	WCI.020 - General Stationary Combustion (Mixed Waste)	0.41%				
4	WCI.020 - General Stationary Combustion (Wood Waste)	0.83%				
5	WCI.280 - Mobile Equipment at Facilities (Diesel)	71.70%	• Full recalculation of emissions • Reviewed data assumptions and methods • Reviewed consistency to regulatory defaults, emission factors, and calculation methodologies • Reviewed regulatory compliance • Operational status of vehicle	• Calculation workbooks • Third party invoices • Regulatory parameters • On-site vehicle inventory	As recorded or monthly	• Engineering estimates and assumptions • Default factors from regulatory documents • Review methodology for on-site transportation emissions estimations. • Review vehicle list and operating data. • Review allocation methods for stationary vs. mobile equipment.
6	WCI.280 - Mobile Equipment at Facilities (Gasoline)	2.90%				
7	WCI.200- Wastewater Emissions	0.01%	• Full recalculation of emissions • Reviewed data assumptions and methods • Reviewed consistency to regulatory defaults, emission factors, and calculation methodologies • Reviewed regulatory compliance	• Calculation workbooks • Regulatory parameters	As recorded or annually	• Engineering estimates and assumptions • Default factors from regulatory documents • Review calibration records and maintenance logs for meters and equipment. • Review the Facility's data systems including frequency of data collection. • Interview Facility staff.

Emission Report Verification Statement and Conflict of Interest Report

Template Version 3 – February 2021

1 OVERVIEW

1.1 INTRODUCTION / VERIFICATION OBJECTIVE

The Verification Statement provides the opinion of a Verification Body as to whether a Reporting Operation's Emission Report is free of material errors, omissions or misstatements and conforms to the requirements of the *Greenhouse Gas Industrial Reporting and Control* Act (the Act), the Greenhouse Gas Emission Reporting Regulation (the Regulation), ISO 14064-3 and IAF MD4. The content of the Verification Statement is based on section 31 and 33 of the Greenhouse Gas Emission Reporting Regulation (the Regulation) and must identify information that was not reported or quantified in accordance with the Regulation and indicate whether or not that information was corrected through the verification process. The Verification Statement identifies the materiality of any errors, omissions or misstatements in the Emission Report. Additionally, the Verification Body must ensure the Verification Statement includes, in the form and manner specified by the Director, any additional information required to be included by the Director in accordance with section 31(1)(c) of the Regulation.

1.2 VERIFICATION BODY

General Information	
Verification Body *Regulation s.33(2)(a)*	Dillon Consulting Limited
Business Address *Regulation s.33(2)(a)*	Dillon Consulting Limited 51 Breithaupt Street Suite 200 Kitchener, Ontario, N2H 5G5
Accreditation *Regulation s.33(2)(h)*	ANSI National Accreditation Board (ANAB) #8896
Accreditation Status *Regulation s.33(2)(h)*	Accreditation is in good standing.
Verification Body Team	
Lead Verifier *Regulation s.33(2)(b)*	Zachary Zehr, P. Eng. zzehr@dillon.ca

	519-571-9833 x 3151
Verification Team Members *Regulation s.33(2)(c)*	Martha Hamre, EIT mhamre@dillon.ca 519-571-9833 x 3136 Alyssa Hooge ahooge@dillon.ca T - 604.278.7847 ext. 4234
Independent Peer Reviewer *Regulation s.33(2)(l)*	Jack Wallace, P. Eng. jwallace@dillon.ca 403-215-8880 x 4364

1.3 REPORTING OPERATION

General Information	
Reporting Operation *Regulation s.33(2)(d)*	Newcrest Mining Limited
BCGHG ID *Regulation s.33(2)(d)*	22122200002
Operator *Regulation s.33(2)(d)*	Newcrest Mining Limited Brucejack Mine, BC
Operation Representative *Regulation s.33(2)(d)*	Jason Gabora Environmental Coordinator T: +1 778 724 4186 x103 jgabora@pretivm.com
Person Primarily Responsible for Preparing and Submitting the Emission Report	Brittany Moore Environmental Engineer-in-Training

Regulation s.33(2)(d)	Brucejack Operations 2965 Tatlow Road Smithers, BC V0J 2N5 T: +1 778 724 4186 x139 bmoore@pretivm.com
Name of Facility *Regulation s.33(2)(d)*	Brucejack Gold Mine Facility
Facility type:	Single Facility Operation
Facility Address *Regulation s.33(2)(d)*	Brucejack Mine, BC 56°27'55.94"N, 130°11'10.06"W
Individual Facilities within an LFO *Regulation s. 33(2)(d.1), s.14(4)*	Not applicable.
National Pollutant Release Inventory Identification Number *Regulation s.33(2)(d)*	29072
Process flow diagram *Regulation s.33(2)(d), s.30(4)(c)*	Confirmed that a process flow diagram was submitted and that it is accurate and reliable for the purposes of the verification.

1.4 VERIFICATION SCOPE

Verification Scope	
Reporting Period: *Regulation s.33(2)(d)*	Janaury 1, 2021 to December 31, 2021
Scope of Verification Statement *Regulation s.33(2)(f)*	Please identify the circumstances that apply in relation to the Reporting Operation and the scope of the Verification Statement (check all that apply):

	The Emission Report to which this Verification Statement applies was prepared for a Reporting Operation for the purpose of submitting an application to the CleanBC Industrial Incentive Program.	☐
	The Reporting Operation had Attributable Emissions over 25,000 tonnes CO_2e, not including Reporting-Only Emissions, during the reporting period for which this verification statement applies.	☒
	The Reporting Operation had Attributable Emissions over 25,000 tonnes CO_2e, not including Reporting-Only Emissions, at least once in the previous three reporting periods (not including the reporting period to which this Verification Statement applies).	☒
	The Reporting Operation had Attributable Emissions less than 25,000 tonnes CO_2e, not including Reporting-Only Emissions, during the reporting period for which this verification statement applies.	☐
	A Supplementary Emission Report to which Section 29 (1) or (2) of the Regulation applies was required.	☐

1.5 REPORTING OPERATION EMISSIONS

Reporting Operation Emissions	
Total Emissions Attributable to the Reporting Operation during the Reporting Period.	29,743 tonnes CO_2e
Total Emissions *that are not* Reporting-Only Emissions Attributable to the Reporting Operation during the Reporting Period.	7,314 tonnes CO_2e
Total Reporting-Only Emissions Attributable to the Reporting Operation during the Reporting Period.	22,429 tonnes CO_2e

Total amount of carbon dioxide *from non-Biomass* that is Attributable to the Reporting Operation during the Reporting Period.	28,233 tonnes CO_2
Total amount of carbon dioxide *from Biomass not listed in Schedule C* of the Regulation that is Attributable to the Reporting Operation during the Reporting Period:	43 tonnes CO_2
Total amount of carbon dioxide *from Biomass listed in Schedule C* of the Regulation Attributable to the Reporting Operation during the Reporting Period:	242 tonnes CO_2

2 VERIFICATION PROCESS

2.1 SITE VISITS

Site Visits	
Fill out the following information for each site visited, including head office visits. Add additional lines for multiple facilities.	
Site Visited *Regulation s.33(2)(j) and s.30(3)*	Brucejack Gold Mine Facility
Type of Site Visit *Regulation s.30(3)(a)*	Conducted in-person
Date of Site Visit *Regulation s.33(2)(j) and s.30(3)*	March 30, 2022
Information and Communication Technology (ICT) used *IAF MD4: 2018* *Regulation s.33(2)*	Not applicable, as an in-person site visit was performed.

Risk identification and mitigation *IAF MD4: 2018* *Regulation s.33(2)*	Not applicable, as an in-person site visit was performed.
Requirements for virtual site visits *Regulation s. 30(4)*	Not applicable, as an in-person site visit was performed.

3 VERIFICATION FINDINGS

Dillon performed data checks of all supporting information and data provided by the Facility. A complete list of the documents provided to Dillon during the verification is presented in **Table B**.

The issues log was developed to summarize the data checks completed by Dillon and present any material and immaterial discrepancies that Dillon identified during verification. Any issues identified were documented in the issues log. The Facility would have an opportunity to respond to the issues identified in the issues log through verbal communication or email correspondence. The final issues log detailing all issues and their resolutions is provided in **Table C**. There were no unresolved qualitative or quantitative findings associated with the data or data management systems.

Assessment of Data Management Systems and Controls

Newcrest made available to Dillon all documentation that supported a review of the Facility Emission Report. These records include meter and raw data, operational records and logs, data management systems, quality assurance and quality control (QA/QC) practices, quantification methodologies, and staff interviews. A complete list of the documents provided to Dillon during the verification is presented in Table B.

The site has physical and digital data collection, and data is retained indefinitely in Newcrest's digital data management system. Data collected in physical data collection forms are digitized and stored. The source of data is acceptable for use in the Emission Report.

Dillon assessed the information systems and controls for sources of potential errors, omissions, and misrepresentations, taking into consideration the following:

- Selection and management of the GHG data and information;
- Processes for collecting, processing, consolidating, and reporting GHG data information;
- Systems and processes that ensure the accuracy of the GHG data and information;
- Degree of automation;
- Use of database features;
- Length of operation;
- Linkage to other systems;
- Standardization within an organization;
- Transparency of calculations;
- Design and maintenance of the GHG information system;
- Systems and processes that support the GHG information system; and
- Results of previous assessment.

Assessment of GHG Sources and Calculation Methodologies

Table 1 below presents Dillon's assessment of emissions data for the 2021 Submission for each SSR included in the GHG boundary and for Production. A complete list of the documents provided to Dillon during the verification is presented in **Table B**.

Table 1: Assessment of Data Findings

SSR/ Production	Verification Findings
Consistency with Previous Years	Dillon reviewed the emissions reported in 2020 and 2021 and identified a 1.3% increase in overall attributable emissions
WCI.020 – General Stationary Combustion	General stationary combustion consists primarily of backup diesel generators and propane space heaters. Additionally, solid waste materials are incinerated at the Brucejack and Knipple camp sites. Several pits are used for open burning of clean wood waste (pallets, clearing debris), with volumes estimated by dimensions logged and a default void content and density applied. The fuels combusted include: • Propane; • Diesel; • Wood waste; and • Mixed solid waste.

SSR/ Production	Verification Findings
	Newcrest applied default emission factors under Part 020 of the WCI guidelines, as listed in Table 20-1 though Table 20-7, and default material property values from IPCC (2006) Volume 5: Waste for the estimation of waste emissions from incineration. Default organic and fossil carbon content values are applied based on the type of material combusted. The material breakdown of each batch incineration batch is assessed visually and logged. The methodology for waste combustion was modified from 2020 to 2021 to follow Methodology 1 of WCI.23 rather than formulas from IPCC (2006) as previously referenced. The emission factor for N_2O was revised to reference WCI Table 20-7. Based on bulk diesel delivery to the site, diesel consumption is allocated to stationary equipment based on equipment run hours, power ratings from manufacturer specifications (generator cut sheets), and default load factors. Dillon completed a recalculation of stationary combustion emissions using raw data from invoices as well as observations on the engineering estimates from the site visit and default emission factors and carbon contents (waste). Minor discrepancies were identified due to the availability of generator cut sheet information which detail fuel loads, which are not material.

SSR/ Production	Verification Findings
WCI.280 – Mobile Equipment at Facilities	All gasoline is used for mobile equipment. Based on bulk diesel delivery to the site, and diesel consumption allocated to stationary combustion, the remainder of the diesel delivered to site is allocated to mobile equipment use. Newcrest applied default emission factors under Part 020 of the WCI guidelines, as listed in Table 20-2. Part 280 of the WCI guidelines were followed for general procedures such as sampling frequency and data management. Dillon completed a recalculation of mobile equipment emissions using raw data from invoices and default emission factors. Minor discrepancies were identified due to generator cut sheet information referenced for General Stationary Combustion calculations, which are not material.
WCI.200 – Wastewater Emissions	Newcrest reported N_2O emissions from the aerobic wastewater treatment systems, following methodologies under Part 200 of the WCI guidelines. Total nitrogen in effluent results based on the permitted composite sample are used. Dillon completed a recalculation of wastewater emissions using raw data from total nitrogen results and wastewater flow. Minor discrepancies were identified due to wastewater volumes which are not material.
Production	Gold and silver production is tracked through the weigh data of final product using calibrated weigh scales. Weigh scales are checked with a traceable test weight before and after every recorded production weigh-in. Product is weighed prior to loading on shipment vehicles. Electricity is purchased from the grid-supplied network and invoiced monthly. Dillon reviewed electricity invoices. Dillon did not identify any discrepancies in the production reported under CIIP.

3.1 ERRORS, OMISSIONS, MISSTATEMENTS AND OPPORTUNITIES FOR IMPROVEMENT

Identified Error, Omission or Misstatement	Material/Immaterial	Resolution
Stationary Fuel Combustion	Immaterial -66.65 tonnes of CO_2e	Not resolved

	-0.22% of total	
Mobile Equipment	Immaterial 66.65 tonnes of CO_2e 0.22% of total	Not resolved
Wastewater:	Immaterial 0.01 tonnes of CO_2e 0.00004% of total	Not resolved
Summary Misstatements		
Total Absolute Misstatement	0.01 tonnes of CO_2e 0.00004% of total reported emissions	
Opportunities for Improvement		
Opportunities for improvement	No Opportunities for Improvement were identified.	

4 DECLARATIONS

LEAD VERIFIER DECLARATION

In signing this declaration, I certify that:

- the Emission Report was prepared and the Emissions reported in it were quantified in accordance with the Regulation;
- the verification of the Emission Report was conducted in a manner consistent with ISO 14064-3 and IAF MD4 requirements, and in accordance with the Act and the Regulation;
- any information that is required but was not included in the Emission Report, any information that was not reported or quantified in accordance with the Regulation, and the materiality of any errors, omissions or misstatements, has been identified in the Verification Statement;
- any information required by the Director has been included in the Verification Statement; and
- a Conflict of Interest Report was completed prior to verifying the Emission Report, showing that the Verification Body is qualified under the Regulation to complete the verification.

The evidence obtained by the Verification Body during the verification is sufficient and appropriate to support the verification opinion. Based on the processes and procedures conducted and described in

this Verification Statement, the Verification Body is satisfied the Emission Report, including the total Attributable Emissions, for the Reporting Period is materially correct, and a fair and accurate representation of the Reporting Operation's total Attributable Emissions for the Reporting Period in accordance with the verification criteria, in all material respects, and are substantiated by sufficient and appropriate evidence.

The Verification Statement is true, accurate and complete.

Verification Body-Signatory Name and Title:	Zachary Zehr, P.Eng. Associate
Signature:	Signatory is authorized to represent the Verification Body.
Date:	2022/05/31

INDEPENDENT PEER REVIEWER DECLARATION

In signing this form, I certify that I was not involved in the verification documented in the Verification Statement, other than providing an independent peer review, and that the verification used to produce the Verification Statement was appropriate

Name and Title:	Jack Wallace, P.Eng. Associate
Signature:	
Date:	2022/05/31

5 APPENDIX A: CONFLICT OF INTEREST REPORT

1 ASSESSMENT AND PROCEDURES

1.1 ASSESSMENT OF THREATS TO INDEPENDENCE -SECTION 41 (3)

Prior to issuing a proposal to the client for GHG verification services, Dillon's verification team reviewed the assignment to determine if there are any threats that would impact impartiality. Regardless of who at Dillon received or solicited the opportunity, the opportunity was forwarded on to Dillon's Climate Change Partner. The Climate Change Partner reviewed the opportunity at the Policy, Organization level to determine if there are any threats to impartiality.

Upon approval, the Climate Change Partner worked with the applicable Program Manager and Staffing Coordinator to assign a competent Project Team. Once assigned, each Project Team Member was required to complete an internal Project Impartiality, Resources and Conflict (PIRC) Form for the assignment indicating that they do not have any perceived threats against COI or impartiality. Dillon completed this process for the verification of the Facility, and as a result of this process and the PIRC Form, did not identify any threats to independence or conflicts of interest requiring further mitigation.

In addition to the Climate Change Partner's involvement in screening opportunities, a Risk Screening Partner is engaged to review opportunities from a corporate risk and impartiality perspective. The Risk Screening Partner role spans all of Dillon's service sectors. The role of the Risk Screening Partner and their competencies are outlined within Dillon's Quality Management System. Specifically relating to GHG projects, the Risk Screening Partner will be responsible for the following:

- Review contracts relating to risks (financial, liability, etc.), and provide as necessary with the Dillon Business Administration Manual, approvals of contracts
- Overall Go/No-Go decisions, utilizing the Climate Change Partner as required, and
- Review corporate level COI considerations and provide approval for proceeding with projects

1.2 MITIGATION PROCEDURES -SECTION 41 (3)

Mitigation procedures were not required based on the assessment completed as described under Section 1.1 above.

1.3 IMPLEMENTATION OF PROCEDURES -SECTION 41 (3)

Not applicable.

2 AFFIRMATION

In signing this document, I certify, on behalf of the Verification Body that:

I am an authorized officer of the Verification Body and have personally examined and am familiar with the information submitted in this Conflict of Interest Report.

Based upon reasonable investigation, including my inquiry of those individuals responsible for completing the assessment and implementing the procedures, I hereby warrant that the Verification Body avoided any actual or potential conflict of interest with the operator of the Reporting Operation or Regulated Operation.

I understand that any false statement made in the submitted information may be a violation of the Greenhouse Gas Emission Reporting Regulation, section 41.

Dear Mr. Chang,

Re: Brucejack Project Environmental Assessment – Hydrogeology Baseline Report

Please find attached a copy of the above-referenced final report, summarizing the baseline hydrogeology study completed in support of the Environmental Assessment (EA) for the Brucejack Project.

We appreciate the continued opportunity to take part in the development of the Brucejack Project; should you have any questions or comments, please do not hesitate to contact me.

Yours sincerely,

BGC ENGINEERING INC.

EXECUTIVE SUMMARY

BGC Engineering Inc. (BGC) was retained by Pretium Resources Inc. (Pretium) to complete a baseline groundwater hydrology, or hydrogeology, study for the Brucejack Project located in northwestern British Columbia, Canada. The Brucejack Project (the Project) is a proposed gold-silver mine previously explored by Newhawk Gold Mines Ltd. during the 1980's and 1990's (Pretium, 2012).

The objective of this report is to define the current understanding of the baseline hydrogeologic conditions in the local study area for the Project. This report will support the Environmental Assessment (EA) Certificate application, to be submitted for the Brucejack Project during 2014.

SPATIAL AND TEMPORAL BOUNDARIES

The baseline hydrogeology assessment was completed for the local study area (LSA) within the Brucejack Creek watershed. The LSA is defined as "*the Project footprint (all physical structures and activities that comprise the Project) and surrounding area within which there is a reasonable potential for immediate effects on a specific intermediate component or receptor VC [valued component] due to an interaction with a Project component(s) or physical activity*" (Rescan, 2013a). For the purposes of a hydrogeologic assessment, such effects may include drawdown due to dewatering, alteration in the flow regime, changes to groundwater recharge and/or discharge, and changes to groundwater chemistry. It is anticipated that the effects on the groundwater system at the Brucejack Project site will be focused around the underground mine development, and that the LSA from a hydrogeologic perspective will extend over a radial distance of a few kilometres from the proposed mine.

Hydrogeological data specific to the Brucejack Project site have been collected since 2010 by BGC, through site investigations associated with a Preliminary Economic Assessment (PEA), a Feasibility Study (FS) and an Environmental Assessment (EA). The most recent data presented in this report are from September 2013.

APPROACH AND METHODOLOGY

This baseline hydrogeologic assessment for the LSA involved the compilation and review of available geological, geotechnical, hydrogeologic, and geochemical data obtained from investigations of the Brucejack site, comprising:

- The drilling and hydraulic response testing completed in boreholes at the site
- Installation and development of groundwater monitoring wells
- Water level monitoring and groundwater sampling conducted at the site in support of the baseline hydrogeologic assessment.

PHYSICAL HYDROGEOLOGIC RESULTS

Surface topography has a pronounced influence on the groundwater flow system at the site. Measured groundwater elevations suggest that the water table is a subdued replica of

topography, with depths to groundwater typically greater in the uplands relative to lowlands, and greater seasonal variation at higher elevations. It follows that, in general, groundwater flow at the site follows topography, with groundwater recharge occurring at higher elevations and groundwater discharge occuring in the vicinity of Brucejack Creek and Brucejack Lake. A component of groundwater flow also occurs westwards, towards the Sulphurets Glacier.

The hydrostratigraphy of the site is composed of a thin, discontinuous layer of glacial till or colluvium underlain by bedrock. Thicker overburden deposits are confined to local sections of the valley bottom and are not present in the vicinity of the proposed underground mine.

Bedrock of the Brucejack Project area can be broadly divided as follows:

- Triassic marine sedimentary and volcanic rocks of the Stuhini Group.
- Jurassic sediments and volcanics of the Hazelton Group.
- Early Jurassic dikes, sills, and plugs of diorite, monzonite, syenite, and granite, the most common of which are grouped as the “Sulphurets Intrusions”.

Site wide, a general trend of decreasing bedrock hydraulic conductivity with depth is observed, though hydraulic conductivity varies by 2 to 3 orders of magnitude at any given depth. Based on available data, there is no apparent relationship between hydraulic conductivity and the major structure in the immediate vicinity of the Brucejack Project, the Brucejack Fault.

Adit dewatering, which occurred from November 2011 to February 2012 and August 2012 onwards, created a pronounced decrease in groundwater elevation in nearby monitoring wells. Dewatering activities also changed hydraulic head gradients, leading to increasingly large gradients associated with downward groundwater flow in areas affected by dewatering.

GEOCHEMICAL RESULTS

For the purposes of this baseline hydrogeologic assessment, and consistent with the requirements of the Project Application Information Requirements (AIR), concentrations of physical parameters, total metals, and dissolved metals were compared to appropriate regulatory guidelines for the protection of freshwater aquatic life (Canadian Council of Ministers of the Environment Water Quality Guidelines; and British Columbia Ministry of Environment (BC MOE) Water Quality Guidelines) and for drinking water use (BC MOE Water Quality Guidelines). Guideline exceedance does not imply contaminated groundwater, but rather suggests that background concentrations are higher than typically found in groundwater at other natural sites in Canada due to mineralization in the area. Observed concentrations are considered to be reflective of the natural site conditions.

In general, all groundwaters sampled present moderate alkaline pH values (~ pH 8), low to below detection limit chloride and nutrient concentrations (e.g., ammonia, nitrate, nitrate) and temperatures of approximately 2°C, with minimal seasonal variation. The groundwater sampled from the monitoring wells were grouped based on the geological model unit surrounding the well screens, and pertain to four material types: Office P1, P2, VSF and Bridge P1. Piper diagrams show all groundwaters present similar major cation concentrations, however anion constituents appear to show material-specific trends. Office P1 is

representative of one end-member, with low sulphate and high alkalinity, and Bridge P1 is highlighted as the opposite end-member. An analysis of bulk chemistries from the four material types revealed several metals presented common exceedances to guideline values. Specifically, six metals are shown to be enriched in all groundwaters sampled at the Project site (i.e., Al, Ag, As, Cr, Cu, and Fe). In addition to these metals, several material-specific enrichments were noted; by geologic mdel unit type these are: P2 (F, total Hg and Zn), VSF (F, total Cd, Co, Pb, and Zn), and Bridge P1 (F, total Cd, Pb, and Zn). These results, coupled with general groundwater chemistries (observed from Piper diagram results), imply Bridge P1 and Office P1 likely represent baseline groundwater high and low end-members (respectively) present at the Project site.

1.0 INTRODUCTION

BGC Engineering Inc. (BGC) was retained by Pretium Resources Inc. (Pretium) to complete a baseline groundwater hydrology, or hydrogeology, study for the Brucejack Project located in northwestern British Columbia, Canada. The objective of this report is to define the baseline hydrogeologic conditions in the local study area for the proposed Brucejack minse site. This report will support the Environmental Assessment (EA) Certificate application, to be submitted for the Brucejack Project during 2014.

1.1. Project Background

The Brucejack Project is a proposed underground mine targeting a gold-silver deposit in the high alpine in the Sulphurets District of the Iskut River region of British Columbia. The project is located approximately 70 km north-northwest of Stewart and 30 km west of Bowser Lake, at latitude 56°28’20” N and longitude of 130°11’31” W (Drawing 01). Access to the site is via an all-season road that crosses the Knipple Glacier, or via helicopter from one of Bell II, Stewart, B.C., or Grand Duc via Hyder, Alaska.

The Brucejack Project proposes to open a mine in an area previously explored by Newhawk Gold Mines Ltd. during the 1980’s and 1990’s (Pretium, 2012). At the end of Newhawk’s tenure, the project site included camp facilities, shop facilities, a ventilation shaft, an adit, and approximately 5,300 m of exploratory underground development (McLeod, 1999). A major reclamation program was completed in 1999 and the property was placed on a schedule of care and maintenance (McLeod, 1999).

The Brucejack Project was acquired by Silver Standard Resources Inc. in 1999-2000, and subsequently by Pretium Resources Inc. following the discovery of the Valley of Kings Zone in 2009-2010 (Pretium, 2013). Active exploration has been ongoing at the site since that time, including a bulk sample excavation from the Valley of Kings in 2013. A *Feasibility Study and Technical Report* was completed for the project, and submitted in June 2013 (Tetra Tech, 2013).

The proposed underground operation is to be located to the southwest of Brucejack Lake (Drawing 02). The project will include development of a mill adjacent to Brucejack Lake for primary processing of the ore. Flotation tailings from this mill will be deposited in Brucejack Lake along with waste rock from the underground mine. Waste rock and paste thickened tailings will also be used to backfill portions of the underground mine. Concentrate produced at the mine site will be hauled off-site by truck along the 70 km long access road that connects to Highway 37.

2.0 SCOPE OF WORK

This report is based on a review of the results from geological, geotechnical and groundwater quality investigations conducted by BGC on behalf of Pretium, and presents the conceptual understanding of the pre-construction and pre-mining hydrogeologic setting of the Brucejack Project. Predicted effects of the project on groundwater hydrology during construction, operations and closure (decommissioning and reclamation) and post-closure are addressed under separate covers (BGC, 2013a; 2013b).

The assessment was completed in general accordance with the requirements of Section 5 of the *Water and Air Baseline Monitoring Guidance Document for Mine Proponents and Operators* (British Columbia Ministry of Environment [BC MOE], 2012), and is generally consistent with the document *Groundwater Mapping and Assessment in British Columbia* (Resource Information Standards Committee [RISC], 2013). This report has also considered information requirements outlined in Section 4.1 of the document *Framework for a Hydrogeologic Study in support of an application for an Environmental Assessment Certificate under the Environmental Assessment Act and Regulations* for groundwater extraction projects (BC MOE, 2013). Finally, the study meets requirements in *Brucejack Gold Mine Project: Application Information Requirements for Pretium Resources Inc.'s Application for an Environmental Assessment Certificate* (BC EAO, 2014), the 'AIR', and in *Environmental Impact Statement Guidelines for the Brucejack Gold Mine Project* (CEAA, 2013), the 'EIS'.

2.1. Temporal Boundaries

Hydrogeological data specific to the Brucejack Project site have been collected since 2010 by BGC, through site investigations associated with a Preliminary Economic Assessment (PEA), a Feasibility Study (FS) and an Environmental Assessment (EA). The most recent data presented in this report are from September 2013.

2.2. Spatial Boundaries

There are nine groundwater regions in British Columbia, classified in relation to physiography (Foweraker, 1994). The proposed mine site lies within the Coastal Mountains sub-region of the Insular and Coastal Mountains physiographic region. Parsons and Quinn (1994) provide a general overview of the groundwater occurrence, recharge and quality for the Insular and Coastal Mountains, which extend from the United States border to the Yukon. The extent of the Coastal Mountain sub-region and location of the project area are shown on Drawing 03.

2.2.1. Regional and Local Study Areas

The regional study area (RSA), defined as "*the spatial area within which direct and indirect effects are anticipated to occur*" (Rescan, 2013a), comprises the area selected for numerical hydrogeologic modeling, discussed in more detail in the report entitled *Brucejack Project Environmental Assessment – Numerical Hydrogeologic Model* (BGC, 2014a).

The baseline hydrogeology assessment was completed for the local study area (LSA) within the Brucejack Creek watershed. Catchment boundaries for the Brucejack Creek watershed are shown on Drawing 04.

The LSA is defined as "*the Project footprint (all physical structures and activities that comprise the Project) and surrounding area within which there is a reasonable potential for immediate effects on a specific intermediate component or receptor VC [valued component] due to an interaction with a Project component(s) or physical activity*" (Rescan, 2013a).

For the purposes of a hydrogeologic assessment, such effects may broadly include:

1. Drawdown of the water table or hydraulic heads due to mine dewatering;
2. Accompanying changes in groundwater recharge and/or discharge rates; and/or,
3. Changes to groundwater chemistry from geochemical reactions within the mine or waste materials, or within any zones that are dewatered.

It is anticipated that these stresses to the groundwater system at the Brucejack Project site will be focused around the underground mine development, and that the LSA from a hydrogeologic perspective will extend over an approximately radial distance of a few kilometers from the proposed mine.

3.0 SITE DESCRIPTION

3.1. Physiography

The Brucejack Project is located within the Boundary Range of the Coast Mountain Physiographic Belt along the western margin of the Intermontane Tectonic Belt. The region is characterized by steep mountains and extensive glaciation. Within the local project area, elevations vary from 1,300 to 2,000 m asl. Prominent depositional and erosional features that have resulted from glaciation include melt water channels on sloping surfaces, and small depressions frequently occupied by ponds and lakes. No permafrost conditions have been observed in the Project mine site area.

The tree line is at approximately 1,200 m elevation; therefore the mine site is sparsely vegetated. Sparse fir, spruce, and alder grow along the valley bottoms, and scrub alpine spruce, juniper, alpine grasses, moss, and heather cover the steep valley walls (Rescan, 2011a).

3.2. Climate & Meteorology

The climate at lower elevations in the regional study area is generally that of a temperate or northern coastal rainforest, with subarctic conditions at the high elevations where the Brucejack Project is located. An orographic influence of increased precipitation with increased elevation is often observed in mountainous terrain (Loukas & Quick, 1996). This same effect is expected within the study area, the result being highly variable precipitation and air temperature (Rescan, 2012). Though the Brucejack Project is located more than 200 km inland from the Pacific Ocean, lower mountains near the coast and a corridor created by Behm Canal, Burroughs Bay, and the Unuk River valley allow penetration of maritime air to the mine site area and subsequent abundant precipitation.

Meteorology baseline studies for the Brucejack Project were initiated in 2009, with the installation of an automated meteorological station near the site at an elevation of 1,360 m asl (Rescan, 2012). Precipitation and climate have also been monitored within the region at the Unuk River – Eskay Creek (#1078L3D) and Bob Quinn (#1200R0J) stations. Both stations are operated by Environment Canada from 1989 – present and 1977 – 1994, respectively.

The estimated mean annual adjusted precipitation at the Brucejack meteorological station is 1,589 mm based on data collected from January 2010 to December 2012 (Rescan, 2013b). This may under-predict precipitation, however, as the high wind speeds at the project site may result in under-catch. Average annual precipitation estimated by ClimateBC (Wang, 2012) for an elevation of 1,400 m asl exceeds 2,000 mm, as does annual average precipitation observed at lower-elevation Unuk River – Eskay Creek station. Average monthly precipitation data from the Brucejack Lake, Unuk River – Eskay Creek, and Bob Quinn meteorological stations, as well as estimates from the ClimateBC model, are presented Table 1. Data from all stations indicate that most of the precipitation occurs over the winter months, while the meteorological

station at Brucejack Lake indicates that the highest average monthly precipitation in the LSA occurs during September.

From October to May, most precipitation falls as snow. At higher elevations, snow accumulation can reach between 10 m and 15 m, while snow accumulation in low river valleys ranges from 2 m to 3 m (Rescan, 2011a). Strong winds in all seasons at high elevations in the project area lead to significant redistribution of snow (Rescan, 2012). The length of the snow-free season varies from about May through November at lower elevations and from July through September at higher elevations. Monthly mean air temperatures range from approximately -10°C in December and January to +10°C in July and August for this area (Rescan, 2011a). These temperatures are generally similar to regional climate normals for the Unuk River – Eskay Creek station.

3.3. Hydrology

The local study area contains glaciated areas, as well as several streams, wetlands and lakes, the largest of which is Brucejack Lake. Brucejack Lake is located in the immediate vicinity of the Brucejack Project within a relatively small sub-basin (10.1 km^2) of the Sulphurets Creek watershed (300 km^2). Sulphurets Creek is a tributary to the Unuk River (2,577 km^2) which flows southwest, draining into the Pacific Ocean to the northeast of Ketchikan, Alaska.

The hydrology of the project area is characteristic of a snowmelt dominated regime supplemented by glacier meltwaters in the late summer. Peak flows typically occur in mid-summer and low flow conditions occur during the winter months of January to March (Rescan, 2013a). The long period of snow and ice cover limit evaporation at the site. The local terrain at the Brucejack Project is steep, with elevations ranging from 1,300 to 2,000 m above sea level.

The Brucejack Lake catchment is approximately 41% glaciated (Rescan, 2013c), however, estimates of glacier contributions to streamflow are not yet available.

Data collection for a hydrology baseline study for the Brucejack Project commenced in 2010 (Rescan, 2011b). The baseline study includes data from automated hydrometric stations installed by Rescan during 2007 and 2008 to characterize the hydrology at a neighbouring property. The hydrometric stations relevant for the Brucejack Project are BJL-H1 (Drawing 04) and SL-H1 which collect continuous water level data downstream of Brucejack Lake and Sulphurets Lake, respectively.

Average monthly and annual streamflow, and runoff data for the area are presented in Table 1, along with the precipitation data. Streamflow data are from the hydrometric station BJL-H1 which is located at the discharge point of an approximately 11.7 km^2 catchment area containing the Brucejack Lake sub-basin and three intervening tributaries (Drawing 04). Runoff estimates, which are calculated from streamflow, are expected to represent all of the runoff from the upstream watershed, as baseflow bypassing the hydrometric station is not believed to be susbstantial (BGC, 2014b). The highest average monthly runoff occurs during the months of May through August, and is mostly related to snowmelt in late May and throughout the summer.

This meltwater also appears to act as a significant source for groundwater recharge (discussed further in Section 6.2).

Average annual runoff of 1,746 mm is reported, based on available monthly streamflow data over the period of 2007-2012 (Rescan, 2013d). This estimate exceeds the estimated annual precipitation of 1,589 mm. The discrepancy between annual precipitation and runoff could be related to any one or combination of the following justifications:

1. Prevalent orographic effect causing a difference in precipitation amounts at the two station locations;
2. Precipitation underestimates due to under-catch; or,
3. There is a significant contribution to runoff from glacial melt (BGC, 2014b).

3.4. Geology

The regional geology of the area has previously been described in detail by Grove (1971, 1986), Alldrick (1989), Britton and Alldrick (1988), Alldrick and Britton (1988), Roach and MacDonald (1992), McPherson et al., (1994) and Savell (2008). Regional geology is illustrated on Drawing 05, while site-specific geology is summarized briefly in Sections 3.4.1 though 3.4.4; for more detail on local geology, refer to the FS level rock mechanics assessment completed by BGC and provided under separate cover (BGC, 2013b).

Pretium's geological model units (shown on Drawing 06 and cross-sections 12 and 13) are discussed in Section 3.4.5, in relation to site-specific geology.

3.4.1. Overburden

The overburden in the LSA consists of a veneer of well-graded glacial till over bedrock. Grain size varies from sand to gravel, with some silt and clay, and variable quantities of cobbles and boulders. Clasts are subrounded to rounded, and color varies from orangey brown to grey. Overburden thickness varies but is generally less than 5 m, often less than 1 m, and occasionally absent. A thin (often less than 0.5 m, but occasionally up to 3.0 m) layer of sandy organics overlies the overburden.

3.4.2. Bedrock Geology

The Brucejack Property is underlain by Upper Triassic volcaniclastic and epiclastic sedimentary rocks of the Stuhini Group and Lower to Middle Jurassic volcanic, volcaniclastic, and sedimentary rocks of the Hazelton Group. An angular unconformity marks the contact between the sedimentary rocks of the Stuhini Group and medium- to coarse-grained sandstones of the Jack Formation which is the basal formation of the Hazelton Group and is dated at about 196 million years (Ma).

The sedimentary rocks belonging to the Jack Formation are overlain by a 10-50 m thick unit of mudstone/argillite and cherty argillite belonging to the Unuk River Member of the Betty Creek

Formation. This argillaceous unit is exposed along the southwest side of the West Zone deposit.

Overlying the argillite unit is a 500 m thick package of hornblende and plagioclase-phyric andesitic flows, flow breccias and intermediate tuffaceous rocks intercalated with volcaniclastic conglomerates, sandstones and siltstones. These rocks form the bulk of the Unuk River Member in the Brucejack Property and outcrop extensively within a northwest-trending belt that passes beneath Brucejack Lake. U-Pb geochronology and biochronology done by Mineral Deposit Research Unit (MDRU) geoscientists have determined the age of the Unuk River Member volcanics to be in the range of 196 to 194 Ma.

The rocks of the Unuk River Formation are overlain by a thick sequence of dacitic pyroclastic rocks (tuff-breccia, lapilli tuff, crystal-lithic tuffs, minor ash tuff) and flows with thin argillite interbeds belonging to the Brucejack Lake Member of the Betty Creek Formation. These are exposed on the mountainside north of Brucejack Lake.

The intrusive Unuk River Member andesites are the most important host rocks to the gold and silver bearing quartz veins discovered in the Brucejack Property (P&E Mining Consultants, 2009), and are the focus of the proposed development in the Valley of Kings (VOK) and West Zone (WZ).

3.4.3. Lithologies and Alterations

Multiple stages and zones of alteration have been noted in the project area. The rocks in the VOK and WZ are highly altered, and in many cases stratigraphic relationships must be used on top of lithologic descriptions. The main lithologies include:

- Volcanics: Felsic, intermediate, and mafic volcanics as well as mafic dykes
- Porphyries: Plagioclase-hornblende porphyritic rocks, potassium feldspar-hornblende-plagioclase porphyritic rocks, and plagioclase porphyritic rocks
- Intrusives: Felsic, intermediate, and mafic intrusives
- Sediments: Conglomerates, sandstone/arenite, mudstone/siltstone/pelites, carbonates, cherts/jasperites
- Hydrothermals: Quartz veins, quartz-carbonate veins, quartz-silicate veins, hydrothermal replacement, hydrothermal breccias, and intensely silicified breccia zones
- Metamorphics: Metamorphosed felsic igneous rock, and metamorphosed intermediate to mafic igneous rocks (these lithologies present only at the adjacent Snowfields property)
- Fault zones

Alteration assemblages vary with proximity to deformation events, but sericitic alteration is pervasive throughout the project area. Carbonate, chlorite, and silica alteration are also common.

As summarized by Greig (2012), mid-Cretaceous deformation, which represents the major phase of regional deformation, has deformed both the mineralized zones and the host stratigraphy and therefore post-dates the mineralization event. The regional event led to the development of the predominant WNW to ENE trending and very steeply dipping foliation best displayed in the altered rocks which are the immediate hosts to the mineralization. Late stage brittle faulting has locally disrupted some of the earlier tectonic fabrics. There is evidence for northerly, northwest, and northeast fault trends.

Two major phases of folding are present on the property. Although their origin is uncertain, they may have been developed during the mid-Cretaceous event. One fold axis generally trends northerly but with an arcuate shape, and the other is a tightly folded syncline plunging to the east-southeast with the above-mentioned dominant foliation primarily axially parallel to it. Both fold axes are steeply plunging.

3.4.4. Major Structures and Faulting

The major regional lineaments, as interpreted by ERSi (2010), around the Brucejack area are the Brucejack Fault lineament, the Upper Treaty Glacier lineament and the Treaty Creek lineament. The Bruce Fault, a west-trending fault occupying Brucejack Creek was also identified at earlier stages of exploration as a major feature at the site (McPherson et al., 1994).

The Brucejack Fault truncates several site-scale faults at the western extent of the Brucejack property, and thus has been interpreted as post-dating site-scale deformation events. Orientations parallel to the inferred Brucejack Fault lineament were commonly observed in downhole structural measurements across the property. All interpreted structural domains include sets oriented along the Brucejack Fault with dips ranging from 56˚ to vertical.

The Upper Treaty Glacier lineament is a prominent high angle topographic lineament north of the Brucejack property. Although not associated with a specific fault set, similarities in regional topography and drainages make it likely that parallel structures will be prevalent throughout the study area. The Upper Treaty Glacier appears in drill hole and underground mapping data in the northern regions of the property, and appears locally in the West Zone and VOK 1 domains as a moderately strong shear and joint set. It also aligns with the topographic lineament used to define the VOK 2 – VOK 3 structural domain boundary (BGC, 2013b).

The Treaty Creek lineament strikes east-southeast and extends north to the Iskut River Fault. The lineament marks the contact between the Hazelton Group and Bowser Lake Group rocks to the north of the property, and is a common orientation for valleys and drainages in the region. It is expected that lineament-parallel steep structures will be prevalent throughout the study area. The Treaty Creek lineament was observed in drill hole data as a joint and shear set throughout the property, and parallels the VOK 1 – VOK 2 domain boundary.

The Brucejack Fault lineament is currently the only known major structure that intersects the proposed mining footprint. It is a northerly striking anastomosing fault zone located along the western margin of the study area and extends north to the Iskut River Fault. In places the

lineament appears to be several sub-vertical to moderately (greater than 60°) dipping fault strands braided together. The zone has normal faulting with variable displacement estimated at 500 to 800 m (ERSi, 2010).

3.4.5. Geological Model Units

As discussed above, the Brucejack Property contains a wide range of rock types, with 24 unique rock lithologies identified by Pretivm geologists from drill core. Mapping within the Brucejack area shows many of these rock types are intensely altered and this, in addition to a diverse range of mineral assemblages, adds to the difficulty in relating logged drill core to stratigraphic sequences.

Pretivm developed a geological model to relate these logged lithologies to 7 model units that best categorize the rock composition:

- P2 Model Unit – characterized as megacrystic, plagioclase, K-feldspar and hornblende phyric flow. Sulphide content comprises pyrite with minor sphalerite and trace chalcopyrite.
- Fragmental Model Unit – characterized as Hornblende and/or feldspar phyric latite to andesite fragmental volcanic rocks and subordinate flows with minor ash and lapilli tuff. Sulphide content comprises pyrite with minor sphalerite and trace chalcopyrite.
- Conglomerate Model Unit – characterized as Heterolithic boulder to course cobble conglomerate with sandstone. Sulphide content comprises pyrite with minor sphalerite and trace chalcopyrite.
- Silicified Cap Model Unit – characterized as Silicified rocks; typically poorly sorted heterolithic conglomerate, lesser sandstone and local mudstone; commonly includes rhyolite fragments. Sulphide content comprises pyrite with minor sphalerite and trace chalcopyrite.
- Volcanic Sedimentary Facies (VSF) Model Unit – characterized as Volcanically derived siltstone and sandstone with minor arenite and pebble conglomerate. Sulphide content comprises pyrite with minor sphalerite and trace chalcopyrite.
- Office P1 Model Unit – characterized as Hornblende, feldspar phyric latite flows. Sulphide content comprises pyrite with minor sphalerite and trace chalcopyrite.
- Bridge P1 Model Unit – characterized as Hornblende, feldspar phyric latite flows. The Bridge P1 unit is the same general rock type as Office P1 but with a different age and geochemical signature. Sulphide content comprises pyrite with minor sphalerite and trace chalcopyrite.

For the geochemical characterization of the site, sample materials are classified as one of the seven geological model units based on geochemical assay results (i.e., Ti/V) and/or its proximity to intensely silicified rocks located within the central part of the deposit (BGC, 2014d).

4.0 GROUNDWATER RESOURCES

4.1. Regional Groundwater Resources

Regional groundwater resources were assessed by reviewing information available from the BC Ministry of Environment (MOE) Water Stewardship Division and other online resources.

Groundwater in the mountains generally occurs within voids and fractures in bedrock and can be irregularly distributed due to the variability of the fractures (Parsons and Quinn, 1994). Variations in permeability and topographic relief have a strong effect on the direction of groundwater flow, and mountain springs are common where lower permeability rock impedes the downward movement of groundwater.

Groundwater generally occurs in the intervening valley fill deposits between mountain ranges in granular deposits such as sand and gravel, however, low permeability deposits are often present and are not suitable as sources of groundwater supply. The Insular and Coastal Mountains include significant thicknesses (up to hundreds of metres) of unconsolidated material in the valleys which dissect the mountain ranges due to glacial processes during the Pleistocene ice age (Parsons and Quinn, 1994).

Parsons and Quinn (1994) indicate that groundwater quality is generally dependent on the mineral composition of rocks that the groundwater moves through. In areas with base metal mineralization, groundwater may have high concentrations of these metals and may not be suitable for drinking water. In crystalline bedrock of low solubility, the groundwater is typically good quality for drinking water and other uses. Mountainous terrain is considered especially vulnerable to contamination due to generally sparse soil cover and limited natural attenuation and retardation of flow in crystalline fractures.

4.2. Local Groundwater Resources

The BC MOE online British Columbia Water Resources Atlas (BCWRA) did not show any aquifers mapped in the vicinity of the proposed mine LSA. The nearest wells shown in the BCWRA are located approximately 40 km to the east, northeast and northwest of the project site. A map showing the locations of these wells in relation to the project site and Bowser Lake is included as Appendix A, along with associated well records.

There are a total of six wells within approximately 40 km of the Brucejack project site. One well is mapped to the east of the project site in the Wildfire camp area and is owned by Pretium Exploration. Two wells are mapped to the northeast of the project site and are owned by Vallard Construction and designated for commercial and industrial use. Three wells are mapped to the northwest of the project site and owned by Alta Gas. Of these wells, two are designated for commercial and industrial use and one is designated for “other” uses.

A groundwater supply well is proposed for the Brucejack Project site but this well had not been sited, drilled or tested at the time of report writing. Results from a desktop potable groundwater supply well assessment for Brucejack Mine Camp (BGC, 2014c) indicated that:

1. Selecting a successful location for potable groundwater supply wells for the Brucejack Camp will be difficult, and may not be able to supply the maximum demand (i.e., 500 person camp).
2. A bedrock well may only yield approximately an estimated 20 US gallons per minute. A field of three wells (two operating and one back-up well to be used during maintenance and redevelopment of the main production wells) may be sufficient to supply a 50 person camp.
3. Some treatment of the groundwater from the mineralized area may be required to meet drinking water quality standards.

Based on the absence of public-domain hydrogeologic information, the preliminary evaluation of groundwater resources within the local study area is based entirely on site investigations conducted by BGC. Available information on groundwater occurrence and quality and on aquifer formation parameters are discussed in the subsequent sections of this report.

5.0 APPROACH AND METHODS FOR ASSESSMENT

This baseline hydrogeologic assessment for the LSA involved the compilation and review of available geological, geotechnical, hydrogeologic, and geochemical data obtained from investigations of the Brucejack site. The subsequent sections discuss:

1. The installation and development of groundwater monitoring wells
2. The geotechnical drilling and hydraulic response testing completed in boreholes at the site
3. Water level monitoring and groundwater sampling conducted at the site in support of the baseline hydrogeologic assessment.

5.1. Groundwater Monitoring Wells

In the fall of 2011, nine groundwater monitoring wells were installed at six different locations in the vicinity of the existing underground workings and proposed new development areas (Drawing 06). The monitoring wells were completed as three sets of nested shallow and deep wells (MW-BGC11-BJ-1A/B, MW-BGC11-BJ-3A/B, and MW-BGC11-BJ-5A/B), and three individual wells (MW-BGC11-BJ-2A, MW-BGC11-BJ-4A, and MW-BGC11-BJ-6A).

Between June and August 2012, an additional twelve groundwater monitoring wells at two existing locations (MW-BGC12-BJ-4B, MW-BGC12-BJ-6B) and five new locations were installed at the Brucejack site (MW-BGC12-BJ-8A/B, MW-BGC12-BJ-9A/B, MW-BGC12-BJ-10A/B, MW-BGC12-BJ-11A/B, MW-BGC12-BJ-12A/B). The monitoring wells are identified with either the letters ‘A’ or ‘B’, to differentiate the deep (A) and shallow (B) well in each nest.

The locations for the installation of monitoring wells were selected based on the following considerations:

- Locations of the mineral deposits and surface water receptors (i.e., Brucejack Creek and Brucejack Lake);
- Good spatial distribution of groundwater elevation data;
- Locations of existing vibrating wire piezometer installations;
- Access to wells during the winter; and,
- Proximity to Brucejack Fault.

Originally, nested wells were planned for each site, however, the number of installations and depths were adjusted based on static water levels observed in the field and the presence or absence of water bearing fractures. For example, at MW-BGC11-2A it was determined that a shallow completion was not necessary because the static water level was deeper than 50 m. Installation depths varied from 8.8 to 103.3 m and well screen intervals were selected based on the intersection of water bearing fractures and on the depth to static water level.

Drilling of the PQ-sized holes for monitoring well installations was conducted by Radius Drilling Corporation and Matrix Diamond Drilling using heli-portable diamond drills. Drilling fluid consisted of freshwater obtained from Brucejack Lake, Brucejack Creek, or other nearby

surface bodies of water. No drilling additives or muds were used for the groundwater investigation drill holes, with the exception of MW-BGC12-BJ-12A which was drilled with grease to get past a significant discontinuity at an approximate depth of 50 m bgs. Where overburden thickness exceeded 0.3 m, a short length of surface casing was installed to facilitate drilling and monitoring well installation.

Monitoring wells were constructed using 2” solid pvc, and 0.20 slot PVC screens. Wells were completed with 10/20 silica sand packs placed around the screened intervals, and 3/8” coated bentonite pellet seals placed above the sand packs. The borehole annulus above the bentonite plug was filled with a cement-bentonite grout. The 2011 monitoring wells could not be grouted at the time of installation due to winter drilling conditions and available supplies on site, though the bentonite plugs above the sandpacks in the boreholes and at ground surface are considered sufficient to maintain the integrity of these monitoring wells. Completion of the 2011 wells is documented in the memo entitled *Brucejack Project – Preliminary Summary of October 2011 Groundwater Investigation* (BGC, 2012).

Following installation, BGC developed all monitoring wells by removing approximately 10 well volumes of water from the wells and monitoring the stability of field chemistry parameters, namely pH, electrical conductivity (EC), temperature, and total dissolved solids (TDS). Groundwater was removed from the wells using dedicated Waterra inertial pumps fitted with surge blocks, dedicated bailers, an air compressor, or by removing a length of PVC casing and allowing the well to flow naturally (for artesian wells MW-BGC11-BJ-3A and -3B). Well development was considered to be sufficient once the field parameters stabilized and there was no further visual improvement in water quality.

Following well development, pressure transducers (HOBO data loggers by Onset Corporation) were installed in all monitoring wells which collect continuous water level measurements at 6-hour time intervals.

Well logs and drill hole details for the Brucejack site groundwater monitoring wells are provided in Appendix B and summarized in Table 2. The locations of the monitoring wells are shown on Drawing 06.

5.2. Vibrating Wire Piezometers

Three geotechnical drill holes were completed by BGC at Brucejack in 2010 as part of a geotechnical site investigation that also included borehole televiewer surveys, packer testing and the installation of vibrating wire piezometers (VWPs). Nested shallow and deep VWPs were installed in two of the angled geotechnical drill holes (SU-82, SU-88), with a single VWP installed in the third (SU-77). Continuous single-channel data loggers set to record measurements of pressure and temperature at 6-hour intervals were attached to all VWP installations.

In the spring and fall of 2012, an additional 17 geotechnical drill holes were completed as part of FS-level underground and plant site investigations (Drawing 06). A total of 18 VWPs were

installed in 12 of the drill holes (Table 3) and attached to continuous single-channel data loggers recording at 6-hour intervals. Standpipe piezometers were installed in three of the shallow geotechnical holes (DH-BGC12-28, DH-BGC12-29, and DH-BGC12-30), with the same procedures and materials described above in Section 5.1.

Geotechnical drill hole logs are provided in Appendix C with borehole details summarized in Table 3. Details on the vibrating wire installations, including VWP tip coordinates and depths, are provided in Table 4.

5.3. Hydraulic Response Testing

5.3.1. Packer Tests

Packer testing is a method for obtaining hydraulic conductivity estimates in rock, and may be performed using a single or double packer set-up. There are three different types of packer tests that can be performed:

1. Constant head tests (i.e., constant pressure)
2. Falling head tests
3. Flow recession tests.

Of these, constant head packer tests are preferred, as information can be gained on both the permeability of the tested interval and the rock and fracture behaviour.

The general procedure for conducting a packer test involves isolation of a predetermined testing interval within a borehole by lowering packers down the hole inside drill rods and inflating them with nitrogen gas or water. After isolation, a constant pressure head is applied to the test interval and maintained using a pump located at the surface. For each test, three ascending and two descending pressure stages were applied. A flow totalizer was used to record the total volume of water that is pumped down the hole during each test over a given time (generally 5 to 10 minutes per stage). The bulk hydraulic conductivity across the test interval may then be estimated using a formula involving the applied pressure differential, the observed steady-state flow rate, and an empirical shape factor based on the geometry of the test interval.

A falling head test may be conducted if the hydraulic conductivity is found to be too low to perform a constant head test (i.e., hydraulic conductivity less than ~$1x10^{-8}$ m/s at which flows are generally too low for measurement using commercially available, non-specialized, flow metres). This type of test typically involves addition of water to a predetermined level within the drill rods and recording the rate at which the water level drops, and is very similar to the procedure described below in Section 5.3.2.

A flow recession test may be performed if the sealed packer interval is found to be flowing artesian. For this test, the artesian interval is sealed and the pressure buildup over time is recorded. After the pressure has stabilized, the interval is unsealed and the discharge rate monitored until pressure in the interval returns to pre-test conditions.

Hydraulic conductivity data from a total of 52 packer tests carried out in the bedrock at the Brucejack Site were available for analysis and review. Six packer test results were available from 2010 investigations at the site, with an additional 46 results obtained during the 2012 site investigations. Hydraulic conductivity values estimated from packer tests are summarized in Table 5.

5.3.2. Slug Tests

Rising and falling head tests were carried out by BGC in 2012 to obtain estimates of the hydraulic conductivity of the near-surface, fractured rock zone in which the monitoring wells are completed. Generally, the procedure for these tests involves bailing water from, or adding a displacement slug to, a monitoring well and measuring the resulting water level recovery with time. Test results were analyzed using the Hvorslev (1951) method to estimate the hydraulic conductivity of the formation around the test interval.

A total of 15 falling or rising head tests were conducted in monitoring wells at the Brucejack Site during the 2012 site investigations. Results of the rising and falling head slug test analyses are summarized in Table 6.

5.4. Water Level Monitoring

Hydraulic head data were collected by the network of data loggers attached to VWPs and pressure transducers deployed in groundwater monitoring wells (Sections 5.1 and 5.2). These data loggers were downloaded during each site visit, depending on accessibility and status of the water column (i.e., frozen or unfrozen). Hydraulic head data were corrected for barometric pressure and are plotted as groundwater hydrographs along with climate data in Appendix D.

Hydraulic head data from data loggers were supplemented by manual water level measurements in standpipe piezometers. Static groundwater levels and total well depth were measured from a notch cut at the top of the PVC pipe at each monitoring well using a water level tape, and well stick-up height was measured using a measuring tape. Given the topographic relief, the measurement accuracy of 0.01 m for groundwater levels is considered adequate for baseline characterization of the groundwater flow system in the Brucejack Project LSA. Water level measurements were not always possible during the winter months due to deep snow cover prohibiting access to the wells, or due to frozen water columns. Manual water level measurements from groundwater monitoring wells are presented along with installation and lithologic data in Table 2.

5.5. Groundwater Sampling

Groundwater samples have been collected from monitoring wells at the Brucejack site on a quarterly basis since installation, though weather and site access occasionally prevented a monitoring well from being sampled during a given sampling event, particularly during the winter. The general methodology for groundwater sampling is summarized below.

In general, at least three well volumes were purged from monitoring wells to remove stagnant water from the well and filter pack prior to collection of groundwater samples. For wells screened in low permeability formations, less than tree well volumes may have been purged prior to sampling due to slow well recovery. Purging was conducted using Waterra inertial pumps, dedicated polyethylene bailers, mini-monsoon pumps, or for later sampling events Grundfos Redi-Flo 2 pumps. All pumps were used with dedicated tubing for each monitoring well. Purge volumes were measured in 20 L pails, and discarded at ground surface away from the borehole annulus. For all purging methods an effort was made to minimize agitation of the water column, to reduce sediment suspension in sample water.

During purging, in-situ parameters (pH, temperature, and EC) were monitored until relatively constant readings were observed (i.e., constant temperature, 0.1 pH variation, 2-5% EC variation). It was assumed that water in the well was formation water representative of in-situ groundwater conditions when these parameters were determined to be stable.

Samples were collected from each well using dedicated Waterra tubing with inertial or mechanical pumps, or dedicated single-use polyethylene bailers and placed into the appropriate sterile sample containers provided by the laboratory. Samples were filtered and/or preserved as required and were stored in coolers with ice packs at approximately 4°C until they were transported under chain of custody to ALS Environmental Laboratories in Burnaby, BC for analysis.

The samples were submitted for analysis of physical parameters, anions, nutrients, cyanides, organic carbon, total metals, and dissolved metals. Quality assurance and quality control (QA/QC) samples including field blanks, travel blanks and field duplicates were submitted as required, and were tested for the same parameters as the groundwater samples. In general, one set of field blanks and one set of travel blanks were included with each sampling event, along with one set of duplicates, which equates approximately to a 1:10 ratio. Results of groundwater sampling are summarized in Appendix E and lab certificates are compiled in Appendix F.

6.0 PHYSICAL HYDROGEOLOGY RESULTS

Results of the physical hydrogeologic investigations based on the approach and methods for data collection described in Sections 5.1 to 5.4 are described in the subsections that follow. Specifically, this includes discussion of:

1. Hydraulic conductivities in the LSA;
2. Groundwater elevation data;
3. Groundwater flow directions;
4. Hydraulic gradients and groundwater recharge and discharge; and,
5. The occurrence of groundwater springs and seeps.

6.1. Hydraulic Conductivity

Hydraulic conductivity data from a total of 67 hydraulic tests (15 slug tests and 52 packer tests) carried out in bedrock at the Brucejack Site were available for analysis and review. Six packer tests results were available from 2010 investigations at the site, with an additional 46 results obtained during the 2012 site investigations. Slug tests completed in monitoring wells at the Brucejack project in 2012 provide another 15 estimates of hydraulic conductivity. Hydraulic conductivity data are presented in Tables 5 and 6.

Hydraulic conductivity data are illustrated schematically versus depth by test type (i.e., packer test or slug test) in Drawing 07, by lithology in Drawing 08, and by discontinuity class (i.e., 0-1 discontinuities, 2+ discontinuities, or fault zone) in Drawing 09. The general trend of decreasing hydraulic conductivity with depth (or with increasing confining stress) shown is commonly observed within bedrock, and is illustrated in Figure 6-1 from Rutqvist and Stephansson (2003).

Though a general trend of decreasing hydraulic conductivity with depth is observed in site data, hydraulic conductivity is observed to vary by two to three orders of magnitude at any given depth. The geometric mean of hydraulic conductivity estimates from slug tests (8.3×10^{-7} m/s) is higher than the geometric mean of estimates from packer tests (1.5×10^{-7} m/s). This is expected, as site monitoring wells have well screens within 100 m of ground surface, and were installed to target conductive zones in order to facilitate groundwater quality sampling for the purposes of the EA baseline monitoring program. Packer tests, while generally targeting conductive features as well, were completed over intervals at depths reaching up to 500 m below ground surface.

Figure 11. Permeability measured in short-interval well tests fractured crystalline rocks in Gidea, Sweden. Effects of shear dislocation and mineral precipitation/dissolution processes obscure the dependency of permeability on depth (stress). The permeability values on the left-hand side represent intact rock granite, whereas the permeability values on the right-hand side represent highly conductive fractures.

Figure 23. Schematic representation of possible permeability changes at shallow and deep locations in fractured bedrock. The solid lines represent the depth-(or stress-) permeability function for intact rock, clean tension joints and highly conductive and locked-open fractures.

Figure 6-1. Permeability vs. Depth - from Rutqvist and Stephansson, 2003.

Overburden permeability data are not available in the immediate vicinity of the Brucejack Project, though estimated hydraulic conductivity from falling head tests conducted within boreholes and in standpipe piezometers in the overburden during the 2008 and 2009 drilling programs by Rescan and KCBL at a neighbouring property ranged from $1x10^{-5}$ m/s to $3x10^{-9}$ m/s, with a geometric mean of $2x10^{-7}$ m/s (BGC, 2010b).

6.2. Groundwater Elevation

As described in Section 5.4, hydraulic head data are collected by the network of data loggers attached to VWPs and pressure transducers deployed in monitoring wells, and supplemented by manual water level measurements in standpipe piezometers. Plots of groundwater elevation through time for instruments installed at the Brucejack site are included in Appendix D.

The VWPs installed in 2010 have the longest continuous record of groundwater elevation at the site, with data extending back to September of 2010. These hydrographs show pronounced annual variation in groundwater elevation for a given location, with water levels slowly decreasing over the course of the winter season, and recovering rapidly with the recharge that occurs during snowmelt. In general, groundwater elevations are observed to mimic topography (i.e., higher groundwater elevations in instrumentation completed at higher elevations and vice versa), and show greater seasonal variation at higher elevations.

Groundwater levels in the monitoring wells varied over the monitoring period by over 30 m at higher elevations (MW-BGC11-BJ-5A/B) and less than 5 m at lower elevations (MW-BGC11/12-BJ-4A/B and MW-BGC11/12-BJ-6A/B). Observed hydraulic heads at the Brucejack Project site ranged from at or just above ground surface, typically at lower elevations (e.g., MW-BGC11-BJ-3A/B), to 60-80 m below ground surface (e.g., MW-BGC12-BJ-12A).

Interpretation of hydraulic head data at the Brucejack Project is complicated by dewatering and drilling activity at the site. Adit dewatering, which occurred from November 2011 to February 2012, created a very pronounced decrease in the water table in nearby wells, with some water levels dropping below the level of the pressure transducers (e.g., greater than 30 m decrease in groundwater elevation in MW-BGC11-BJ-1A, with water level dropping below the level of the data logger in December 2011). Dewatering recommenced in August 2012, and has been ongoing on a continuous basis, though at a variable pumping rate since that time, maintaining the groundwater elevation at approximately the 1300L in the WZ.

Drilling associated with mineral exploration and geotechnical investigations has also impacted groundwater levels within the LSA, as drilling involves the rapid, localized injection of water on a sporadic basis throughout the Brucejack Project area. This is reflected in the groundwater hydrographs as a spiky pattern of rapidly fluctuating water levels in some wells (e.g., MW-BGC11-BJ-5A/B).

6.3. Potentiometric Surface and Groundwater Flow Direction

Using groundwater elevations measured in the Brucejack Project area, BGC prepared interpreted equipotential contour maps for both summer (Drawing 10) and winter (Drawing 11) baseline conditions. The summer contour map was created using groundwater elevations measured in August 2012. Because winter groundwater elevations observed in 2012-2013 were impacted by dewatering activity at the site, a combination of groundwater elevations from 2011, 2012, and 2013 were used to create the interpreted winter groundwater elevation contour map. Data were selected based on the absence of a dewatering or drilling signal, from the months of March and April when the water table reached its lowest elevation in each well.

BGC also prepared two interpreted hydrogeologic cross sections for the project area showing summer groundwater elevations and hydraulic conductivity data in relation to Pretium's geologic block model. Cross section alignments are shown on Drawing 06 and the cross sections are included as Drawings 12 and 13 in this report.

Groundwater flow in the LSA generally occurs downward and northward from the Valley of Kings Zone under topographically driven gradients towards Brucejack Creek and Brucejack Lake. A component of flow appears to be directed westwards towards the Sulphurets Glacier. Pronounced seasonal variation is observed in the potentiometric surface, with lower groundwater elevations occurring in winter months, though no prominent changes to overall flow direction are observed.

There are three deep VWPs (DH-BGC12-19, SU-88D, and SU-77) at which pressures corresponding to low groundwater elevations are consistently observed; these suggest structural controls (e.g., faults or other discontinuities) or a deeper component of flow directed westwards towards the Sulphurets Glacier. These low groundwater elevations, in particular the observation at SU-77, distort the flow field for both summer and winter baseline conditions, though it is unclear whether the low pressure observation at this location represents a deep water table or rather is indicative of a strong gradient driving downward flow.

6.4. Vertical Gradients and Recharge/Discharge Zones

Vertical hydraulic gradients were calculated using groundwater elevation data from nested groundwater monitoring wells where simultaneous measurements were available. For nested wells, a higher groundwater elevation in the shallow well vs. the deeper well indicates a hydraulic gradient driving downward flow, whereas a higher groundwater elevation in the deeper well indicates an upward flow direction. Vertical hydraulic gradients calculated from manual water level measurements in March, August, and September 2012, as well as January, April, July, and September 2013 are summarized in Table 7. Vertical gradients based on data logger records are plotted over time on Drawings 14 and 15 for each well nest with available data.

The interpretation of gradients is complicated by ongoing dewatering and drilling activity at the Brucejack site, as discussed in Section 6.2 (Groundwater Elevation). Vertical gradients between March and August 2012 are considered to be the most representative of baseline groundwater conditions because they are not affected by dewatering of underground workings at the site, which occurred from November 2011 to February 2012 and from August 2012 onwards. However, exploration drilling, in addition to geotechnical and hydrogeologic drilling all occurred between March and August 2012, potentially disturbing hydraulic gradients.

Nested monitoring wells completed at lower elevations (e.g., MW-BGC11-BJ-1A/B, MW-BGC11-BJ-3A/B, and MW-BGC11/12-BJ-4A/B) have small vertical gradients (0.00 – 0.05) associated with upward groundwater flow under baseline conditions. Nested wells in the VOK Zone (e.g., MW-BGC11-BJ-5A/B and MW-BGC12-BJ-12A/B) appear to be in a groundwater recharge zone with vertical gradients associated with downward flow. Monitoring wells MW-BGC12-BJ-8A/B and MW-BGC12-BJ-10A/B had slight gradients driving upward groundwater flow in August 2012, and MW-BGC11/12-BJ-6A/B appear to have consistent, small gradients driving downward flow.

The timeseries plots of vertical hydraulic gradients (Drawings 14 and 15) show clear dewatering impacts within the LSA. For example, wells MW-BGC11-BJ-1A and -1B respond immediately to dewatering. During the first dewatering period at the site (Nov 2011 – Feb 2012), an abrupt reversal of hydraulic gradient was observed, causing the flow direction to quickly shift from upward to downward. During the second, and ongoing dewatering period, the hydraulic gradient associated with downward groundwater flow has become more pronounced as dewatering progresses.

Nearby well pairs MW-BGC11-BJ-3A/B and MW-BGC12-BJ-8A/B also appear to respond to dewatering, though to a lesser degree. Well pairs MW-BGC11-BJ-5A/B and MW-BGC12-BJ-11A/B, located in the VOK, do not show an immediate response to dewatering, though develop strong (>0.8) hydraulic gradients driving downward groundwater flow in the months following the August 2012 start of dewatering. This may be related to the VOK drift advanced for the bulk sample. Wells located farther from the adit and new VOK development (e.g., MW-BGC11-BJ-4A & MW-BGC12-BJ-4B, MW-BGC11-BJ-6A & MW-BGC12-BJ-6B) do not appear to be impacted by dewatering, and generally present small hydraulic gradients.

6.5. Springs and Seeps

Springs and seeps represent natural groundwater discharge, and can be used as an indicator of in-situ geochemistry. They are often found in topographic lows or where permeable rock units overlie rocks of much lower permeability (Figure 6-2). Seeps and springs can also occur where faults or fracture zones daylight in low permeability rock, where groundwater movement is principally through these fractures (Fetter, 2001).

Figure 6-2. Types of springs - from Fetter, 2001.

To date, no seeps or springs have been observed above the ground surface at the Brucejack Project site. Seeps have been observed in the underground and these chemistries were used to estimate scaling factors for the derivation of underground water quality source terms. More details can be found in Lorax (2014).

7.0 GROUNDWATER QUALITY RESULTS

As noted previously, groundwater monitoring and sampling have been carried out at the Brucejack site since October 2011 on a quarterly basis, with the objective of determining baseline groundwater quality prior to mine development. All wells were sampled during these events, with the exception of those that were inaccessible due to depth of snow or potentially hazardous conditions.

On-site drilling operations, during these sampling periods, have the potential to impact water quality sampling. Therefore, the groundwater quality dataset is curated to remove those samples that are identified as 'influenced by drilling operations' and no longer represent baseline conditions. A discussion of the conditions to identify these samples is also included in the succeeding sections.

Groundwater samples were analyzed for physical parameters, major cations and anions, nutrients, cyanides, organic carbon, dissolved metals and total metals (Table 8). The analytical chemistry results for groundwater samples collected during each sampling event are summarized in Appendix E. All samples are compared to the regulatory framework outlined in the AIR and the EIS, as described in Section 7.1 below.

A geochemical assessment of the groundwater at Brucejack is detailed herein by way of review of major water quality indicators to improve the conceptual understanding of the LSA hydrogeology.

7.1. Regulatory Framework

In compliance with the EIS and AIR, the groundwater data collected as part of the baseline assessment is compared with British Columbia Ministry of the Environment (BC MOE) and Canadian Council of Ministers of the Environment (CCME) guidelines. Specifically, as outlined in Section 8.3.1 of the AIR, groundwater data are compared to:

- British Columbia Water Quality Guidelines for Protection of Freshwater Aquatic Life (BC MOE AW) and Drinking Water (BC MOE DW) (BC MOE 2010)
- Canadian Water Quality Guidelines for the Protection of Aquatic Life (CCME FW) (CCME 2012b).

Within the Environmental Management Act (BC MOE, 2011), the water quality guidelines provide numerical concentrations for the evaluation of groundwater quality. The groundwater standards are divided into different categories based on specified uses, such as aquatic life (AW), irrigation, livestock watering or drinking water (DW). The BC MOE AW and DW guidelines specify concentrations for total concentrations of heavy metals, metalloids, and inorganic ions as well as dissolved concentrations for aluminum and iron. Additionally, the guidelines are divided into 30 day average concentrations and maximum one-time concentration. For the purpose of this assessment, all results have been initially compared to the 30 day average concentrations and,in scenarios of 30-day threshold exceedance, the concentrations are subsequently compared to the maximum one-time concentration.

The Canadian Water Quality Guidelines set by the CCME for the protection of freshwater aquatic life (FW) include numerical concentrations to support and maintain the freshwater aquatic environment (CCME, 2012b). The CCME FW guideline values apply to the total element or substance in an unfiltered sample. Within the guidelines, there are thresholds for short-term and long-term concentrations. Results in this assessment are compared with the long-term concentration thresholds.

The full suite of guidelines used in this assessment is shown in Table 9, with additional detail on the calculation of CCME ammonia concentration guidelines provided in Table 10.

As indicated in Table 9, some BC MOE standards and CCME guidelines for metals and metalloids are dependent on hardness, temperature, and/or pH. The hardness-dependent standards and guidelines were calculated using the laboratory reported hardness (as $CaCO_3$) for each sample analyzed. The pH- and temperature-dependent standards and guidelines were compared to the range of pH and temperature measurements recorded in the field during sample collection. Where field pH measurements were not recorded, the analytical results were compared to laboratory reported pH.

Elevated concentrations above the BC MOE or CCME guidelines do not imply that the groundwater at the site is contaminated; rather they suggest that background concentrations of these parameters are higher than typically found in groundwater at other natural sites in Canada due to local mineralization. It should be noted that some areas of the site exist in a disturbed condition due to historical and current exploration activities, however, except where noted, observed concentrations are considered to be reflective of the natural site conditions.

7.2. Quality Assurance and Quality Control

7.2.1. General QA/QC procedures

To provide sampling data that are meaningful and reproducible, a Quality Assurance/Quality Control (QA/QC) program is incorporated into each sampling event. This program includes careful labeling of samples, identification of boreholes, and collection of trip blanks, field blanks and blind field duplicates.

QA/QC in the field is achieved by careful data collection and double-checking of names and labels. Prior to work, the identification of the monitoring well is confirmed on a map, by locating the relative position of other monitoring wells and by cross-checking the label on the well riser.The labels on the sample bottles are clearly filled out, while at the sample location and confirmed during sample collection. Proper preservation is added (where applicable) and samples are kept in coolers (with ice packs) to minimize changes to a sample's physic-chemical characteristics by warmer temperatures or exposure to sunlight.

Following collection, samples are promptly shipped to ALS Environmental Laboratories (ALS) along with chain of custody (COC) documentation. Upon receipt at ALS, the temperature of the samples is measured and recorded on the COC form. The COC form is part of the QA/QC

process as it links the samples at the time of shipment receipt to the source and records the movement of samples during handling, transportation and analysis.

Field Blanks and Trip Blanks

Field blanks consist of de-ionized water and are submitted in the same laboratory in the same sample bottles/jars as used for other samples. Field blanks provide information on contaminants encountered during the sampling procedure, other samples in the cooler at transport and during lab analysis. Field blanks were prepared during or immediately after sample collection. One field blank was submitted per sampling event.

Trip or travel blanks are prepared by the laboratory and consist of jars filled with de-ionized water. They are shipped along with the empty sample bottles to the field and are returned to the laboratory unopened. The purpose of the trip blank is to determine if sample bottle preparation, delivery, handling or storage have an impact on the integrity of the samples.

Duplicate Samples

Duplicate samples are collected at the same location and time as its replicate sample, using the same procedure. Duplicate samples are submitted as ‘blind’ samples and provide a QA/QC check on laboratory analytical methods and reproducibility. In theory, the duplicate sample should be similar to within 20% relative percent difference (RPD) of the original sample if at least one of the values is greater than 5 times the detection limit (BC Ministry of Water, Land and Air Protection, 2003). The groundwater baseline program designated one duplicate sample to be submitted during each sampling campaign.

7.2.2. Review of QA/QC Results

Results from the QA/QC monitoring program are provided in Appendix E along with full groundwater quality results, and are summarized below:

Field Blanks and Trip Blanks

Concentrations in the 8 field blanks were generally below the detection limit for all parameters. A single field blank (March 2012) exceeded the detection limits for total suspended solids (TSS), total kjeldahl nitrogen (TKN) and total nitrogen. The field blanks from September 2012 contained measureable total lithium, but were slightly above (i.e., 1.3 times) the detection limit value (i.e., 0.00005 mg/L).

Five trip blanks were analyzed as part of the Brucejack groundwater baseline. All trip blanks were below the detection limits except for a single sample (September 2012) with detectable total lithium at 1.2 times the detection limit.

Duplicate Samples

Charge balances were calculated for all duplicate samples using PHREEQC (v.3.0.6; Parkhurst and Appelo, 2013), considering dissolved concentrations select species and parameters (i.e., Ca, Mg, K, Na, SO_4, Cl, F, alkalinity, and pH) and ranged between -4.07% to

1.28%. Charge balances within ± 5% error suggest analytical results account for the major species in a sample's chemistry.

The majority of duplicate samples (i.e., 5 of 7) showed median RPD values less than 7%, for those concentrations with values greater than 5 times the minimum detection limit. The two duplicates with median RPD values greater than 20% were sampled September 2012 and April 7th from MW-BGC12-BJ-4B and MW-BGC11-BJ-2A (respectively). The latter sample showed significantly higher RPDs from total metals, relative to dissolved metals, whereas the former sample showed high RPDs for the majority of parameters analyzed. Specifically, TSS values differ by 6 times and 2 times between the replicate samples from these locations and is suggestive of particulate contamination during sampling.

General parameters and anions (i.e., pH, conductivity, TSS, TDS, turbidty, alkalinity, F, and sulphate) showed mean RPDs less than 20% for all duplicate samples tested. Nutrient concentrations (i.e., TKN, Total N, Total P) were less robust and had mean RPDs greater than 30%. Total metal concentrations were more susceptible to larger RPDs, relative to dissolved metals, which suggests particulate concentrations may govern these RPD exceedances. This observation is supported by the high median TSS (i.e., > 100 mg/L) concentrations from 10 (of 14 sampled) groundwater locations.

7.3. Laboratory Results

Groundwater quality results for all samples collected in groundwater monitoring wells on the Brucejack Project Site are presented in Appendix E, along with timeseries plots for selected parameters. The results are compared to the BC MOE AW and DW guidelines as well as CCME FW regulatory guidelines (Table 9). As described in Section 7.1, the results are compared with BC MOE 30 day average concentrations where these guidelines are available and the long-term maximum concentrations outlined in CCME. Where concentrations exceed these guidelines, the result is indicated by one of bolding, italics or underline dependent on the specific guideline exceeded.

The following sub-sections discuss the curation of the groundwater quality sample dataset, and groundwater chemistry results by geological model unit.

7.3.1. Dataset Curation

A total of 70 unique samples were taken from Brucejack monitoring wells between 2011 and 2013. Each well-specific dataset was curated to remove samples with a high likelihood of contamination from proximal drilling activities, surface water interaction, grout contamination, etc.. Specifically, these quality control measures include a temporal comparision between sampling and on-site actitivities (e.g., drilling and dewatering) and statistical analyses to identify outlier values.

Following this review, it was determined that 18 samples should be removed from the 70-sample dataset, from the following wells:

- MW-BGC11-BJ-03A (n = 1)
- MW-BGC11-BJ-03B (n = 1)
- MW-BGC11-BJ-04A (n = 1)
- MW-BGC12-BJ-04B (n = 4)
- MW-BGC11-BJ-05A (n = 2)
- MW-BGC11-BJ-05B (total concentrations only)
- MW-BGC11-BJ-06A (n = 2)
- MW-BGC12-BJ-06B (n = 3)
- MW-BGC12-BJ-08B (n = 3)
- MW-BGC12-BJ-12A (n = 1)

The reasoning and motivation for removing the above listed samples is discussed in the following sections.

7.3.1.1. MW-BGC11-BJ-3A/B

Two samples, collected from monitoring wells -03A (Sept. 25th, 2013) and -03B (Sept. 4th, 2012), were removed from the dataset due to high likelihood of contamination. Specifically, the chemistry of these samples was observed to be statistically uncharacteristic of their groundwater datasets and several parameters were identified as 'outlier' concentrations. Seventeen parameters from the MW-03A sample presented concentrations that were higher than the reasonable range displayed by this dataset (i.e., TSS; Total N; Total P; Total Al, Sb, As, Cd, Co, Cu, Fe, Pb, Mg, K, Ag, Tl, Zn; Dissolved Sb). A similar scenario was observed for the sample from MW-03B, as 19 parameters were higher than a reasonable range (i.e., TSS; Total Al, Cd, Cr, Co, Cu, Fe,Pb, Mg, Mn, Mo, Ni, K, Se, Ag, Tl, and Zn; Dissolved Tl). The proximity of this nested monitoring well to the underground adit makes it susceptible to underground, as well as surface, drilling/exploration activities.

7.3.1.2. MW-BGC11/12-BJ-4A/B

The first sample from both the shallow (-04A; Oct. 10, 2011) and deep (-04B; Sept 3, 2012) monitoring well was removed from their respective datasets. In both scenarios, groundwater chemistries presented concentrations that were outside of a reasonable dataset range (i.e., TSS; turbidity; Total Sb, Cr, Cu, Ni ± As, Hg, K, Mo, and Zn; Dissolved Sb, K ± As, Co, Mo, Ni, Zn). Three additional samples were removed from the 4B dataset (i.e., April 8, 2013; July 11, 2013; Sept 25, 2013), due to significant increases to measured pHs by 2.0 – 2.5 pH units (i.e., pH 7.8 to pH 9.8 – 10.4) suggestive of grout contamination. As well, these three samples presented significant shifts to major cations concentrations, whereby Na values increased by one order of magnitude or greater and Ca, Mg and K concentrations decreased to extremely low, dilute values (i.e., Ca < 10 mg/L and Mg < 1 mg/L).

7.3.1.3. MW-BGC11-BJ-5A/B

These nested monitoring wells were installed in October 2011 and sampling was discontinued in the following summer (July, 2012) due to the well nest location in an area of significant drilling activity and potential for temporary contamination by drilling fluids. Total suspended solid (TSS) concentrations in these wells show extremely high TSS and turbidity values (4000 NTU). The first deep well (-05A) sample did not show evidence of contamination and will be used in the baseline review, whereas the subsequent two samples (March 28, 2012 and June 26, 2012; -05B) were removed. In regards to the shallow well (-05B), the presence of extremely high TSS values (i.e., > 3800 mg/L) from all three samples collected suggests total elemental concentrations should not be used in baseline water quality analyses. However, dissolved concentrations are comparable to those from 5A and are considered applicable to the baseline water quality discussion.

7.3.1.4. MW-BGC11/12-BJ-6A/B

Groundwater wells 6A and 6B are located on the north side of Brucejack Lake near its outflow to Brucejack Creek. The shallow well (-06A) was installed in October 2011, whereas the deeper well (-06B) was installed the following summer (June 2012). The installation of the deep well resulted in grout contamination of the fractured bedrock surrounding the well screen. As well, grout likely migrated towards the shallow (-06A) well and is assumed to be the source of significant increases to measured pH values (by 1 – 2 pH units). Therefore, two samples (June 26, 2012 and Sept 3, 2012) are removed from the -06A dataset and samples from -06B are not included in baseline groundwater quality analyses.

7.3.1.5. MW-BGC12-BJ-8B

Groundwater well -08B was installed on June 18, 2012, and samples taken 10 days later (June 28, 2012) and on September 5th 2012 show chemistries with significantly higher solute concentrations than the averaged dataset. Coupled with these high concentrations are significantly high TSS and turbidity values that suggest surrounding groundwater may have been temporarily contaminated with drilling waters/mud or require a longer period to be developed or flushed (i.e., TSS = 5340 and 984 mg/L; Turbidity = 6000 and 969 mg/L).

The third sample point from Well -08B (April 8, 2013) was removed due to its significantly high dissolved Al values, in lieu of basic pH (i.e., pH 8.23). These dissolved Al concentrations are not considered real and are likely attributed to possible colloidal material and/or insufficient filtration. In general, Al concentrations are controlled by secondary mineral precipitates (e.g., $Al(OH)_3$(am) or Gibbsite) at pH values greater than 4.0 and very low to negligible Al concentrations (i.e., parts per billion range) are typical of waters with pH values > 5.5.

7.3.1.6. MW-BGC12-BJ-12A

Samples taken on Sept 5th, 2012 from Well -12A (i.e., less than 1 month following its installation) were removed from the -12A dataset. Specifically, September 2012 water

chemistry shows high TSS and turbidity (842 mg/L and 272 mg/L), which is unlike the other 2 samples taken. It should be noted that -12A waters are significantly higher than Well -08A, -08B or tributary waters with respect to several metals.

The above samples are included in Appendix E, but have not been included in the remainder of the assessment. Laboratory reports are compiled in Appendix F, and all groundwater samples were analyzed for the parameter set listed in Table 8.

7.3.2. Groundwater Quality by Geological Model Unit

In this section, monitoring wells are grouped based on geological model units, namely Office P1, P2, Volcanic Sedimentary Facies (VSF) and Bridge P1 (Section 3.4.5). The monitoring wells are grouped in this manner to assist with the identification of trends or characteristic groundwater chemistries specific to one or more geological model units.

7.3.2.1. Office P1

Two sets of nested monitoring wells have well screens seated in Office P1 material; MW-BGC11-BJ-1A/B and MW-BGC12-BJ-8A/B. Both monitoring wells are located in the same area to the southwest of the exploration camp. The former is approximately 50 m to the east side of the Brucejack Fault, whereas the latter is approximately 50 m west of the same fault. This dataset consists of eleven samples, with the majority (i.e., n = 9) collected from -08A (n = 6) and -08B (n = 3). Only one sample was taken from MW-BGC11-BJ-01A and -01B, immediately following installation, due to suspected movement of the well screen and/or well stick-up during the winter period (e.g., frost heave).

The aqueous chemistry from this location is relatively consistent. Specifically, general parameters show pH values between pH 8.0 and pH 8.3 and modest TSS and turbidity concentrations (i.e., < 200 mg/L and < 100 NTU). In regards to anions and nutrients; total alkalinity values are typically 75 ± 10 mg/L, with below detection to low nutrients (e.g., ammonia, nitrate, nitrite and orthophosphate), and fluoride concentrations that are below CCME guidelines. Sulphate values do not show seasonal variation and are approximately 30 – 36 mg/L. Median values of each well are plotted on a Piper diagram (red symbols; Figure 7-1) and results generally suggest groundwater is reasonably similar between the four locations. The one exception is the single sample from MW-BGC-11-BJ-01B, which has 4 to 10 times greater Na concentration than the other samples in this dataset. All other concentrations from -01B are within the range demonstrated by this compiled dataset. Therefore, this sample may represent a groundwater end member of the possible chemistries from Office P1.

Table 11 presents the statistical parameters from each nested well and those values for the 'Office P1' dataset. The compiled Office P1 dataset shows median values exceed CCME and/or BC MOE aquatic life (30-day average) guidelines for total concentrations of Al, As, Cu, Cr and Fe. A few samples show CCME or BC MOE AW exceedances of total Cd (MW-08A), Pb (MW-01A), Hg (MW-08B) and Zn (MW-01A and -08A). Measured total Ag concentrations exceeds BC MOE 30-day average and maximum one-time values in most groundwater wells.

Although Office P1 compiled (median) total Ag values do not exceed these guidelines, the frequency of this observation suggests Ag enrichment is likely characteristic of this material-specific ground. Therefore, groundwater sampled from Office P1 fractured bedrock contains enrichments of total Al, Ag, As, Cr, Cu, and Fe concentration, relative to guideline values.

7.3.2.2. P2

A total of 21 samples were taken from three monitoring wells situated in P2 material (MW-BGC11-BJ-02A: n = 8; MW-BGC11-BJ-03A: n = 7; MW-BGC11-BJ-03B: n = 6). As noted in Section 7.3.1, one sample from the MW-BGC11-BJ-03B dataset was identified as 'likely contaminated' and removed from the baseline dataset. In general, groundwater samples taken from these wells show moderately alkaline pH values (i.e., pH 8.0) with little variation (i.e., ± 0.2 pH units). These waters are typically more turbid than groundwater wells from the Office P1 unit, with ranges between 1.97 to 777 NTU. Alkalinities and sulphate concentrations are also similar between these locations with average values between 75 – 95 mg $CaCO_3$/L and 48 – 101 mg/L (respectively). Piper plots of the dominant cation and anion constituents plot within the same region of the trilinear diagram (Figure 7-1). These results suggest waters from fractured P2 bedrock are comparable and spatially consistent.

Several parameter concentrations show values that are consistently higher than CCME and/or BC MOE aquatic life guidelines. Specificially, total Al, Ag, As, Cr, Cu, Fe, and Zn generally exceed CCME guidelines for most samples, whereas total Ag, Cu, and Zn also exceed BC MOE AW 30-day average values. Total Zn values from MW-03A also exceeds its BC MOE one-time maximum guideline for the majority of samples taken from this location. Fluoride and total Cd, Pb, Se and dissolved Al concentrations exceed CCME and/or BC MOE AW guidelines on a sporadic to frequent basis. Total Hg concentrations from MW-BGC11-BJ-02A and -03A samples show common exceedances to CCME, and were not identified in shallow well (MW-BGC11-BJ-03B) and suggest some spatial variability within the aquifer.

It should be noted that the nested wells MW-BGC11-BJ-03A/B are located close to the underground adit and, following dewatering and active exploration in 2012 through to 2013, several spikes are observed in the samples collected from this location. Given the shorter duration of this dataset, and the potential for influence by nearby exploration activities, these wells were not included in the evaluation for temporal trends.

Bulk groundwater chemistries from P2 material (Table 12) indicate baseline conditions present higher elemental concentrations of F and total Al, Ag, As, Cu, Cr, Fe, Hg, and Zn relative to CCME and/or BC MOE aquatic life guidelines. Note that F and total Hg were included in this dataset given frequency of exceedances in select wells, which may point towards some spatial variability in this material type.

Figure 7-1. Piper diagram showing median groundwater concentrations measured from Brucejack monitoring wells.

7.3.2.3. Volcanic Sedimentary Facies (VSF)

Three nested monitoring well sets are installed in VSF material (i.e., MW-BGC11/12-BJ-04A/B, MW-BGC11-BJ-05A/B, and MW-BGC11/12-BJ-06A/B) for a total of 18 samples. Groundwater chemistries measured from VSF material typically show moderately alkaline pHs (i.e., pH ~ 8.0) and modest sulphate ranges (i.e., 69 – 140 mg/L) relative to those values observed from Office P1 and P2. Alkalinities from the VSF grouped dataset range between 40 – 126 mg $CaCO_3$/L.

The major anion and cation constituents of VSF groundwater chemistries are shown on the Piper diagram in Figure 7-1, relative to those chemistries from Office P1 and P2. These plots show anion concentrations (i.e., sulphate and alkalinity) exhibit the main differences between material-specific chemistries. Specifically, samples from fractured VSF material present higher median sulphate values and lower alkalinities, relative to Office P1 and P2, whereas most samples have similar alkali concentrations (i.e., Ca, Mg, Na, and K).

Compiled results for all monitoring wells in VSF material are shown in Table 13. Floride exceeds CCME guidelines (0.12 mg/L) in all samples with the exception of those from MW-BGC11-04A (Table 13). Dissolved Al shows some values greater than BC MOE aquatic life in a single monitoring well (i.e., MW -06A), and in most cases exceeds the one-time maximum value (i.e,. 0.2 mg/L).

Total Al and Fe concentrations surpass CCME values of 5 – 100 µg/L and 0.3 mg/L (respectively) in all collected samples. Total Cr and As concentrations from most samples exceed CCME and both, CCME and BC MOE aquatic life guideline values.

Measured total Ag, Cd, Co and Cu concentrations surpass CCME or BC MOE aquatic life values in select monitoring wells (i.e., -05A and -06A). Additionally, concentrations of total Pb, Hg, Se, Tl and Zn are highlighted as parameters of concern in MW-BGC11-BJ-06A only. In particular, total Pb values exceed CCME, BCMOE aquatic life 30-day average and one-time maximum, and BC MOE DW values.

A compilation of these results indicates bulk groundwaters from VSF material likely present enriched values of F and total Al, Ag, As, Cd, Co, Cr, Cu, Fe, Pb, and Zn. It should be mentioned, that although median Ag, Cd, Co, Cu and Pb concentrations for VSF groundwater (Table 13) are not above guidelines, they are included in the above list as these metals surpass guidelines values by 10 – 100 times and/or may show spatially signficant enrichments in this material type.

7.3.2.4. Bridge P1

One monitoring well (MW-BGC12-BJ-12A) was situated in Bridge P1 material. Two samples from this well are used in the baseline analysis and, due to the limited sample suite, these results should be considered preliminary. In general, these waters are characterized as very hard (> 181 mg/L), moderately alkaline (pH 7.8) with high sulphate (177 mg/L) concentrations

and moderate alkalinity (104 mg $CaCO_3$/L). Although samples from this location are limited, the average Bridge P1 values are likely identified as distinct from other units when plotted on trilinear diagrams (Figure 7-1). Similar to other observations, the anion constituents from this monitoring well differentiate these waters from those of Office P1, P2 and VSF units.

Concentrations are shown in Table 14 and, in regards to metal exceedances, F, total Al, Ag, Cd, Cr, Cu, Fe, Pb, and Zn concentrations are observed to surpass higher values from BC MOE aquatic life and/or CCME guidelines. Average total As values (0.14 mg/L) also exceed BC MOE drinking water standards by greater than 4 times (i.e., 0.03 mg/L). These 10 parameters (i.e., F and total Al, Ag, As, Cd, Cr, Cu, Fe, Pb and Zn) appear to be naturally elevated in baseline waters.

7.4. Groundwater Quality Summary

The average temperature of most samples was approximately 2°C and minimal seasonal variation was observed. Chloride and nutrient concentrations (i.e., ammonia, nitrate and nitrite) from all samples are observed to be below the lowest guideline value and therefore will not be discussed in this report. The groundwater quality timeseries plots (Appendix E) do not show any evident seasonal or temporal trends. Note that monitoring wells MW-BGC11-BJ-03A/B were not included in this discussion, as observed variations may be equally attributed to their proximity to the underground adit. Specifically, dewatering of the underground may have influenced measured chemistries and underground exploration activities were concentrated in 2013 summer months.

The dominant cation constituents of groundwaters sampled at Brucejack are observed to be comparable, but do resemble a continuum in regards to anion concentrations. Specifically, Office P1 likely represents one end-member with low sulphate and high alkalinity and Bridge P1 resembles the higher end-member with high sulphate and low alkalinity. In addition to major cation/anions, this review of the groundwater quality specific to four geological model units (i.e., Office P1, P2, VSF and Bridge P1) revealed several parameters consistently present high concentrations in all materials tested (Table 15).

Specifically, six metals are shown to be enriched in all groundwaters sampled over the three-year Brucejack sampling campaign (i.e., Al, Ag, As, Cr, Cu, and Fe). Office P1 presents the least amount of exceedances and, coupled with its low sulphate and high alkalinity (Figure 7-1), is likely representative of the least amount of metal enrichment for the Brucejack area. In addition to the six enriched metals listed above, groundwater sampled from VSF-specific monitoring wells is representative of groundwater with the highest amount of metal exceedances (i.e., F, total Cd, Co, Pb, and Zn). Although the dataset from Bridge P1 is limited, groundwater chemistries from this material also present several additional metal exceedances (i.e., F, total Cd, Pb and Zn). These observations, coupled with the lowest alkalinities and highest sulphate values observed from Bridge P1 groundwater samples, suggests this material may be reflective of the groundwater with the highest likelihood for metal enrichment.

8.0 CONCLUDING SUMMARY

The baseline hydrogeologic conditions at the Brucejack Project site are summarized in this report, which includes a detailed description of the site, groundwater resources, methods of hydrogeologic assessment, and physical and geochemical hydrogeologic results. Data in support of the hydrogeologic baseline assessment were obtained through site investigations between 2010 and 2013 that involved:

1. the installation of geotechnical borehole instrumentation and groundwater monitoring wells;
2. hydraulic response testing (packer tests, rising and falling head tests);
3. continuous monitoring of groundwater elevation; and,
4. routine groundwater sampling.

The LSA, located within the Brucejack Creek catchment area, is partially glaciated and is snow-covered from approximately October to June. Snowmelt, which generally occurs in May-June leads to recharge and the rapid recovery of groundwater levels, which decrease slowly over the course of the winter at the site. The LSA is sparsely vegetated, and ET is not considered to have a significant impact on the hydrogeologic system.

Within the fractured bedrock at the site, a general trend of decreasing hydraulic conductivity with depth is observed, although hydraulic conductivity is observed to vary by two to three orders of magnitude at any given depth. The geometric means of hydraulic conductivity estimates from slug tests and packer tests are 8.3×10^{-7} m/s and 1.5×10^{-7} m/s, respectively. Overburden permeability data are not available in the immediate vicinity of the Brucejack Project, though overburden cover is sparse and discontinuous, and not considered to be significant from a hydrogeologic perspective at the site.

In general, groundwater elevations are observed to mimic topography (i.e., higher groundwater elevations in instrumentation completed at higher elevations and vice versa), and show greater seasonal variation at higher elevations. It follows that, in general, groundwater flow at the site follows topography, with groundwater recharge occurring at higher elevations and groundwater discharge occuring in the vicinity of Brucejack Creek and Brucejack Lake. A component of groundwater flow also occurs westwards, towards the Brucejack Fault and Sulphurets Glacier.

Adit dewatering, which occurred from November 2011 to February 2012 and August 2012 onwards, created a very pronounced decrease in groundwater elevation in nearby wells. Dewatering activities impact hydraulic gradients, leading to increasingly strong gradients driving groundwater flow downward in areas affected by dewatering.

For the purposes of this baseline hydrogeologic assessment, concentrations of physical parameters, total metals, and dissolved metals are compared with BC MOE (aquatic life and drinking water) and CCME freshwater guidelines. Seventy unique samples were collected from 14 monitoring wells and, following curation of the dataset to exclude likely contaminated samples, a total of 52 samples were used in the baseline review. In general, the pH of the groundwater is moderately alkaline (~ pH 8) and groundwater temperatures are approximately

2°C, with minimal seasonal variation. All samples from the curated dataset showed chloride and nutrient concentrations (i.e., ammonia, nitrate and nitrite) to be below the lowest guideline values.

Monitoring wells were grouped based on the geological model unit surrounding the well screens. Specifically, groundwater samples pertain to four material types; Office P1, P2, VSF and Bridge P1. An analysis of bulk chemistries from each material revealed several metals presented common exceedances to guideline values. Specifically, six metals are shown to be enriched in all groundwaters sampled over the three-year Brucejack sampling campaign (i.e., Al, Ag, As, Cr, Cu, and Fe). Office P1 presents the least amount of exceedances, whereas groundwater sampled from VSF-specific monitoring wells is representative of the highest amount of metal exceedances (i.e., F, total Cd, Co, Pb, and Zn). Although the dataset from Bridge P1 is limited, groundwater chemistries from this material do present several metal exceedances (i.e., F, total Cd, Pb and Zn).

Piper diagrams show all groundwaters present similar major cation concentrations, however anion constituents appear to show material-specific trends. Office P1 is representative of one end member, with low sulphate and high alkalinity, and Bridge P1 is highlighted as the opposite end-member. These results, coupled with the previous discussion of metal exceedances, imply Bridge P1 and Office P1 likely represent baseline groundwater high and low end-members (respectively) present at the Project site.

9.0 CLOSURE

We trust the above satisfies your requirements at this time. Should you have any questions or comments, please do not hesitate to contact us.

Notes:
1. Drill hole coordinates and elevations for the DH and MW-series holes provided by Pretium from professional surveys in NAD83 UTM Zone 9N, with the exception of DH-BGC12-20 and -21 which are from a handheld GPS and are limited to the accuracy of that tool.
2. "Discons" refers to discontinuities observed during core logging; "STK" indicates stick rock, "DIS1" indicates observation of 1 discontinuity, "DIS2" indicates observation of 2 or more discontinuities, "FAULT" indicates observation of a fault zone.
3. Simplified geology represents the most prevalent geologic material encountered over the packer interval within a borehole, based on core logging completed by BGC and Pretium staff.
4. Incomplete packer test due to failure of packer to seat properly (MW-BGC12-BJ-4B, MW-BGC12-BJ-11B), or insufficient flow (DH-BGC12-21, MW-BGC12-BJ-6B).
5. Unable to achieve pressure required for a constant head test or falling head test. Estimated K represents minimum possible hydraulic conductivity for the interval, derived from estimates of flow at 0 psi.
6. First attempt at MW-BGC12-BJ-9A was drilled using an HQ3 drill head, and was abandoned prior to completion of the hole. Packer test 1a was completed prior to abandonment.

MW-BGC12-BJ-12B	45.2	53.1		(3)		1542.3		(4)		(4)		(4)		(4)		(4)	

Notes:
1. Vertical hydraulic gradients are calculated based on manual water level measurements taken during groundwater sampling events. A positive vertical gradient indicates upward flow, whereas a negative vertical gradient indicates downward flow.
2. Values in grey are considered uncertain; the ground surface was reconfigured at wells 3A/B between April to July 2013, and needs to be re-surveyed before groundwater level data can be accurately corrected to elevation.
3. Groundwater monitoring well not yet installed; no vertical hydraulic gradient calculated.
4. Water level below well screen; no vertical hydraulic gradient calculated.
5. Well slow to respond to development; groundwater elevation data not considered representative of in-situ conditions.

Table 8. Groundwater Quality Parameter Monitoring Set

Parameter Set	Comment
Field parameters	Temperature, pH, Electrical Conductivity (EC)
Laboratory physical parameters	Temperature, Conductivity, Turbidity, TDS, Total Suspended Solids (TSS), pH, Hardness, Colour
Cyanide	Total Cyanide and Weak Acid Dissociable (WAD) Cyanide
Anions	Cl, SO_4, NO_3, NO, Total Alkalinity
Nutrients	Total Kjeldahl Nitrogen (TKN), NH_3, Total Nitrogen, Ortho-PO_4,
Carbon	Total Organic Carbon (TOC), Dissolved Organic Carbon (DOC)
Total Metals	Al, Sb, As, Ba, Be, B, Cd, Ca, Cr, Co, Cu, Fe, Pb, Li, Mg, Mn, Hg, Mo, Ni, P, K, Se, Si, Ag, Na, Sr, Tl, Sn, Ti, V, U, Zn
Dissolved Metals	Al, Sb, As, Ba, Be, B, Cd, Ca, Cr, Co, Cu, Fe, Pb, Li, Mg, Mn, Hg, Mo, Ni, P, K, Se, Si, Ag, Na, Sr, Tl, Sn, Ti, V, U, Zn

[1] British Columbia Water Quality Guidelines for Protection of Freshwater Aquatic Life and Drinking Water (BC MOE), Accessed May, 2014

[2] Canadian Council of Ministers of the Environment (CCME) Water Quality Guidelines for the Protection of Aquatic Life, Accessed May 2014

[3] Background dependent

[4] Ammonia concentration is pH and temperature dependent based on tabulations shown in BC MOE aquatic life guidelines. Assumes average temperature range of 0°C – 5°C and pH range of 7.0 – 8.5

[5] Ammonia concentration is pH and temperature dependent (see Table 10) based on average temperature range of 0°C – 5°C and pH range of 7.0 – 8.5

[6] Fluoride concentration - 0.4 as a maximum where the water hardness is 10 mg/L CaCO3 otherwise use the equation: *LC50 fluoride = -51.73 + 92.57 log10 (Hardness)* and multiply by 0.01

[7] Nitrite concentration – dependent on chloride concentration (0.06 mg/L as a maximum, 0.2 mg/L as a 30 d ave.)

[8] Sulfate concentration – dependent on water hardness: very soft (0-30 mg/L) – 128 mg/L SO4; soft to moderately soft (31-75 mg/L) – 218 mg/L SO4; moderately soft/hard to hard (76-180 mg/L) – 309 mg/L SO4; very hard (181-250 mg/L) – 419 mg/L SO4.

[9] Aluminum concentration - 5 µg/L if pH < 6.5; 100 µg/L if pH ≥ 6.5

[10] Arsenic interim guideline

[11] Cadmium concentration - When the water hardness is > 0 to < 17 mg/L: 0.04 µg/L; At hardness ≥ 17 to ≤ 280 mg/L, calculated using this equation cadmium *(µg/L) = 10{0.83(log[hardness]) – 2.46 };* At hardness > 280 mg/L: 0.37 µg/L

[12] Chromium concentration is for Chromium hexavalent CrVI

[13] Copper concentration (BC MOE)– 30 d average: at hardness ≤ 50 mg/L then less than or equal to 2 µg/L, at hardness > 50 mg/L then less than or equal to *0.04 (mean hardness)* in µg/L; maximum concentration: concentration is *(0.094(hardness)+2)* in µg/L

[14] Copper concentration (CCME) -When the water hardness is 0 to < 82 mg/L, 2 µg/L; At hardness ≥82 to ≤180 mg/L, calculated using this equation: copper *(µg/L) = 0.2 * e{0.8545[ln(hardness)]-1.465};* At hardness >180 mg/L, 4 µg/L. If the hardness is unknown, 2 µg/L.

[15] Lead concentration (BC MOE) – 30 d average: at hardness greater than 8 mg/L, calculated using the equation *3.31 + e(1.273 ln (mean hardness) - 4.704)* in µg/L; maximum concentration: at hardness ≤ 8 mg/L then 3 µg/L total lead, at hardness > 8 mg/L calculated using *e(1.273 ln (hardness) -1.460)* in µg/L.

[16] Lead concentration (CCME) - When the hardness is 0 to ≤ 60 mg/L, maximum is 1 µg/L; at hardness >60 to ≤ 180 mg/L maximum is calculated using this equation concentration (µg/L) = *e{1.273[ln(hardness)]-4.705}*; at hardness >180 mg/L, the CWQG is 7 µg/L. If the hardness is unknown, the CWQG is 1 µg/L.

[17] Manganese concentration – 30 d average: calculated from *0.0044 hardness + 0.605;* maximum concentration: calculated from *0.01102 hardness + 0.54*

Parameter	Unit	BC MOE[1]				CCME[2]

Uranium (U)	mg/L	-	-	0.3[20]		0.015
Vanadium (V)	mg/L	-	-	-	-	-
Zinc (Zn)	mg/L	5	5	0.0075-0.240[21]	0.033-2.65[21]	0.03
Dissolved Metals						
Aluminum (Al)	mg/L	-	0.2	0.005-0.05[22]	0.02-0.1	-
Iron (Fe)	mg/L	-	-	-	0.35	-

[18] Nickel concentration - When the water hardness is 0 to ≤ 60 mg/L, 25 µg/L; at hardness > 60 to ≤ 180 mg/L, calculated using this equation CWQG *(µg/L) = e{0.76[ln(hardness)]+1.06}; a*t hardness >180 mg/L, the CWQG is 150 µg/L. If the hardness is unknown, the CWQG is 25 µg/L.

[19] Silver concentration – 30 d average: at hardness ≤ 100 mg/L concentration is 0.05 µg/L, at hardness > 100 mg/L concentration is 1.5 µg/L; maximum concentration: at hardness ≤ 100 mg/L concentration is 0.1 µg/L, at hardness > 100 mg/L concentration is 3.0 µg/L.

[20] Working guideline based on the water quality guidelines for Ontario.

[21] Zinc concentration – 30 d average: use the equation *7.5 + 0.75 x (hardness -90)*; maximum concentration: use the equation *33 + 0.75 x (hardness -90)*

[22] Aluminum (dissolved) concentration – 30 d average: at pH ≥ 6.5, 0.05 mg/L, at pH <6.5, calculated using $e(1.6 - 3.327\ (median\ pH) + 0.402\ K)$ where K = $(median\ pH)^2$; maximum concentration: : at pH ≥ 6.5, 0.1 mg/L , at pH <6.5, calculated using $e(1.209 - 2.426\ (pH) + 0.286\ K)$ where $K = (pH)^2$.

Table 10. Tabulation of CCME Maximum Long-Term Ammonia Concentration Guidelines

		pH							
		6.0	6.5	7.0	7.5	8.0	8.5	9.0	10.0

STOCKWORK (H7)
Quartz-calcite-rhodochrosite with banded chlorite, abundant galena and sphalerite. Strong to very strong (R4-R4.5). Faint to no alteration (A1).
71.9 - 72.5 m: Brecciated section of stockwork.
72.5 - 74.0 m: Stockwork oriented at 10 degrees TCA.

75.4 - 80.0 m: Wall rock, broken rock, sphalerite, galena, pyrite.

87.9 - 90.2 m: Wall rock, broken rock, galena and sphalerite.

DRILL HOLE # DH-BGC12-19

Project : Brucejack
Project No.1008-007

Location: West Zone

Co-ordinates (m): 426,567E - 6,258,826N
Ground Elevation (m): 1,365.0
Survey Method: Surveyed
Datum: UTM NAD 83 Zone 9
Plunge (°): -75
Trend (°): 131

Drill Designation: Heliportable
Drilling Contractor: Radius
Drill Method: Diamond
Core: HQ3
Fluid: Polymer
Cased To (m) : 16.3

Start Date: 06 Mar 12
Finish Date: 17 Mar 12
Final Depth (m): 425.3
Depth To Top Of Rock (m): 15.1
Logged By: AGC/JND/KM

Project No.1008-007

DRILL HOLE # DH-BGC12-21

Location: Valley of Kings Zone

Co-ordinates (m): 426,406E - 6,258,223N
Ground Elevation (m): 1,499.0
Survey Method: Hand Held GPS
Datum: UTM NAD 83 Zone 9
Plunge (°): -75
Trend (°): 145

Drill Designation: Heliportable
Drilling Contractor: Radius
Drill Method: Diamond
Core: HQ3
Fluid: Polymer
Cased To (m) : 1.8

Start Date: 28 Mar 12
Finish Date: 09 Apr 12
Final Depth (m): 556.6
Depth To Top Of Rock (m): 1.8
Logged By: HKM/JND/LL
Reviewed By: JW

STOCKWORK (H7)
White and grey, varies from coarse sandstone to mudstone. Strong (R4). Fresh (A1).

ARENITE (S4)
Grey, original composition and texture are difficult to discern due to sericite alteration. Massive pyrite increases as replacement clast pyrite decreases. Medium strong to strong (R3-R4). Fresh (A1). Weaker rock (R2.5-R3) from 160.5-180.5 m.

POLYLITHIC CONGLOMERATE (S3)
Grey, poorly sorted, 3 to 30 mm clasts, medium to coarse sandy matrix, moderate pyrite replacement in the matrix. Strong (R4), fresh (A1), discontinuity surfaces are typically very rough with separations <1 mm (JRC = 23).

ARENITE (S4)
Grey, medium to coarse grained, massive sandstone interbedded with mudstones. Sandier intervals contain pebble sized mudstone clasts. Local concretions are present in the finer grained sediments. Medium strong to strong (R3 to R4), fresh (A1), discontinuity surfaces are typically rough to very rough with separations <1 mm (JRC = 18 to 23).

INTERMEDIATE VOLCANICS (V12)
Dark grey tuff breccia. Medium-grained tuff and some pebble-sized porphyry fragments in a dark matrix with fine grained pyrite. Strong (R4), fresh rock (W1), discontinuity surfaces are typically rough with separations < 1 mm (JRC = 16 to 25).

Water table at approximately 15 m during drilling.
