Ceriodaphnia dubia Summary Sheet

Client: Borax (Prefilm)
Work Order No.: 181138

Start Date/Time: July 3/18 @ 1700h
Set up by: VL

Sample Information:

Sample ID: ~~BJ 3-10~~ VL Lab water w/ammonia
Sample Date: June 25/18
Date Received: June 27/18
Sample Volume: 2x 20L

Test Validity Criteria:

1) Mean survival of first generation controls is ≥80 %
2) At least 60% of controls have produced three broods within 8 days
3) An average of ≥15 live young produced per surviving female in the control solutions during the first three broods.
4) Invalid if ephippia observed in any control solution at any time.

WQ Ranges:

T (°C) = 25 ± 1; DO (mg/L) = 4.0 to 8.4 ; pH = 6.0 to 9.0

Test Organism Information:

Broodstock No.: BB062018 A & B
Age of young (Day 0): <24-h (within 8-h)
Avg No. young in first 3 broods of previous 7 d: 32
Mortality (%) in previous 7 d: 5
Individual female # used ≥8 young on test day: 3-10, 32, 35-40

NaCl Reference Toxicant Results:

Reference Toxicant ID: Cd187
Stock Solution ID: 18NaO2 (100g/L NaCl)
Date Initiated: July 4/18

7-d LC50 (95% CL): 2.1 (1.5 – 3.0) g/L NaCL
7-d IC50 (95% CL): 1.4 (1.3 – 1.6) g/L NaCL

7-d LC50 Reference Toxicant Mean and Historical Range: 2.0 (1.8 – 2.3) g/L NaCL CV (%): 6
7-d IC50 Reference Toxicant Mean and Historical Range: 1.3 (0.8 – 1.9) g/L NaCL CV (%): ~~23~~ 24

Reference Information

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
MET-T-CCMS-VA	Water	Total Metals in Water by CRC ICPMS	EPA 200.2/6020A (mod)

Water samples are digested with nitric and hydrochloric acids, and analyzed by CRC ICPMS.

Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.
mg/kg - milligrams per kilogram based on dry weight of sample.
mg/kg wwt - milligrams per kilogram based on wet weight of sample.
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.
mg/L - milligrams per litre.
< - Less than.
D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Reference Information

QC Samples with Qualifiers & Comments:

QC Type Description	Parameter	Qualifier	Applies to Sample Number(s)
Method Blank	Antimony (Sb)-Dissolved	B	L2122750-6, -7
Method Blank	Antimony (Sb)-Dissolved	MB-LOR	L2122750-8, -9
Matrix Spike	Antimony (Sb)-Dissolved	MS-B	L2122750-8, -9

Qualifiers for Individual Parameters Listed:

Qualifier	Description
B	Method Blank exceeds ALS DQO. Associated sample results which are < Limit of Reporting or > 5 times blank level are considered reliable.
MB-LOR	Method Blank exceeds ALS DQO. Limits of Reporting have been adjusted for samples with positive hits below 5x blank level.
MS-B	Matrix Spike recovery could not be accurately calculated due to high analyte background in sample.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
MET-D-CCMS-VA	Water	Dissolved Metals in Water by CRC ICPMS	APHA 3030B/6020A (mod)

Water samples are filtered (0.45 um), preserved with nitric acid, and analyzed by CRC ICPMS.

Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.
mg/kg - milligrams per kilogram based on dry weight of sample.
mg/kg wwt - milligrams per kilogram based on wet weight of sample.
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.
mg/L - milligrams per litre.
< - Less than.
D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Reference Information

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
MET-D-CCMS-VA	Water	Dissolved Metals in Water by CRC ICPMS	APHA 3030B/6020A (mod)

Water samples are filtered (0.45 um), preserved with nitric acid, and analyzed by CRC ICPMS.

Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.
mg/kg - milligrams per kilogram based on dry weight of sample.
mg/kg wwt - milligrams per kilogram based on wet weight of sample.
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.
mg/L - milligrams per litre.
< - Less than.
D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.
mg/kg - milligrams per kilogram based on dry weight of sample.
mg/kg wwt - milligrams per kilogram based on wet weight of sample.
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.
mg/L - milligrams per litre.
< - Less than.
D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Growth IC25	51.6 (33.1 – 75.0)	124.1 (56.1 – 223.1)
Growth IC50	233.1 (165.5 – 321.7)	329.4 (268.6 – 363.5)
NOEC, LOEC	2.8, 5.6	10.1, 15.5

IC = Inhibition Concentration, CL = Confidence Limits, NOEC = No Observed Effect Concentration, LOEC = Lowest Observed Effect Concentration

1.0 INTRODUCTION

Nautilus Environmental Company Inc. conducted 72-h *Pseudokirchneriella subcapitata* growth inhibition toxicity tests for Pretivm Resources in lab water and site water (BJ-3.10) spiked with arsenic (As). Sample BJ-3.10 was collected on June 14, 2021 and delivered to the Nautilus Environmental laboratory in Burnaby, BC on June 16, 2021. The sample was transported in three 20-L plastic containers and was received at a temperature range of 8.5 to 8.9°C. The sample was stored in the dark at 4 ± 2°C prior to testing.

Testing with *P. subcapitata*, was initiated on June 16, 2021. This report describes the results of these toxicity tests. Copies of raw laboratory data sheets and statistical analyses for each test species are provided in Appendices A. The chain-of-custody form is provided in Appendix B.

2.0 METHODS

Methods for the toxicity tests are summarized in Table 1. Testing was conducted according to procedures described by Environment Canada (2007). Statistical analyses for all the tests were performed using CETIS (Tidepool Scientific Software, 2013). Subsamples of each test concentration in lab and site waters were collected and sent to ALS Environmental, Burnaby to confirm that solutions were prepared correctly. Test endpoints were calculated based on measured total As.

Table 1. Summary of test conditions: *Pseudokirchneriella subcapitata* growth inhibition test.

Test species	*Pseudokirchneriella subcapitata*, strain CPCC# 37
Organism source	In-house axenic culture, obtained from Canadian Phycological Culture Center, and originally isolated from Nivelta River, Norway.
Organism age	3-to 7-day old culture in logarithmic growth phase
Test type	Static
Test duration	72 hours
Test vessel	Microplate
Test volume	220 µL
Test concentrations	Eight concentrations, plus laboratory control and site control
Test replicates	4 per treatment; 8 for laboratory control and site control
Number of organisms	10,000 cells/mL
Control/dilution water	Deionized water supplemented with nutrients, site water supplemented with nutrients
Test solution renewal	None
Test temperature	24 ± 2°C
Feeding	None
Light intensity	3600 to 4400 lux
Photoperiod	24 hours light
Aeration	None
Test measurements	Test area temperature measured daily; temperature and pH measured at test initiation; pH of two control wells measured at test termination
Test protocol	Environment Canada (2007), EPS 1/RM/25
Statistical software	CETIS Version 1.9.4
Test endpoints	Algal cell growth inhibition
Test acceptability criteria for controls	>16-fold increase in number of algal cells; CV ≤ 20%; no trend when analyzed using Mann-Kendall test
Reference toxicant	Zinc (added as $ZnSO_4$)

3.0 RESULTS

Results of the toxicity tests are summarized in Tables 2 and 3. For the Lab Water with As the IC25 and IC50 values were 51.6 and 233.1 µg/L total As (measured values), respectively. For the sample BJ-3.10 with As the IC25 and IC50 values were 124.1 and 329.4 µg/L total As (measured values), respectively.

Table 1. Results: *Pseudokirchneriella subcapitata* growth inhibition test.

Lab Water with As	
Concentration µg/L total As (measured values)	**Cell Yield (x 10^4 cells/mL) (Mean ± SD)**
Laboratory Control	21.8 ± 2.5
2.8	19.8 ± 1.5
5.6	17.5 ± 1.3
11.4	18.8 ± 1.7
22.4	19.8 ± 3.1
44.8	16.8 ± 1.3
88.6	13.2 ± 1.7
178	12.8 ± 2.6
348	8.2 ± 1.5
Test Endpoint (µg/L total As) (measured values)	
IC25 (95% CL)	51.6 (33.1– 75.0)
IC50 (95% CL)	233.1 (165.5 – 321.7)
NOEC	2.8
LOEC	5.6

SD = Standard Deviation, IC = Inhibition Concentration, CL = Confidence Limits, NOEC = No Observed Effect Concentration, LOEC = Lowest Observed Effect Concentration

Table 3. Results: *Pseudokirchneriella subcapitata* growth inhibition test.

BJ-3.10 with As	
Concentration µg/L total As (measured values)	**Cell Yield (x 10^4 cells/mL) (Mean ± SD)**
Site Control (BJ-3.10)	58.4 ± 4.1
7.4	53.2 ± 2.6
10.1	62.2 ± 7.8
15.5	49.2 ± 5.7
26.3	49.5 ± 7.0
48.4	48.8 ± 5.0
93.7	47.2 ± 5.2
179.0	39.2 ± 6.1
354.0	28.0 ± 0.8
Test Endpoint (µg/L total As) (measured values)	
IC25 (95% CL)	124.1 (56.1 – 223.1)
IC50 (95% CL)	329.4 (268.6 – 363.5)
NOEC	10.1
LOEC	15.5

SD = Standard Deviation, IC = Inhibition Concentration, CL = Confidence Limits, NOEC = No Observed Effect Concentration, LOEC = Lowest Observed Effect Concentration

4.0 QA/QC

The health history of the test organisms used in the exposure was acceptable and met the requirements of the Environment Canada protocol. The tests met all control acceptability criteria and water quality parameters remained within ranges specified in the protocol throughout the tests. There were no deviations from the test method. Uncertainty associated with these tests are best described by the standard deviation around the mean and/or the confidence intervals around the point estimates.

Results of the reference toxicant tests conducted during the testing program are summarized in Table 4. Results for these tests fell within the range for organism performance of the mean and two standard deviations, based on historical results obtained by the laboratory with these tests. Thus, the sensitivity of the organisms used in these tests was appropriate the reference toxicant tests were performed under the same conditions as those used for the sample.

Table 4. Reference toxicant test results.

Test Species	Endpoint	Historical Mean (2 SD Range)	CV (%)	Test Date
P. subcapitata	Growth (IC50): 35.0 µg/L Zn	32.1 (26.8 – 38.5)	9	June 10, 2021

SD = Standard Deviation, CV = Coefficient of Variation, IC = Inhibition Concentration

Annabelle Prasad	Analyst	Metals, Burnaby, British Columbia
Kevin Duarte	Supervisor - Metals ICP Instrumentation	Metals, Burnaby, British Columbia

General Comments

The analytical methods used by ALS are developed using internationally recognized reference methods (where available), such as those published by US EPA, APHA Standard Methods, ASTM, ISO, Environment Canada, BC MOE, and Ontario MOE. Refer to the ALS Quality Control Interpretive report (QCI) for applicable references and methodology summaries. Reference methods may incorporate modifications to improve performance.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

Please refer to Quality Control Interpretive report (QCI) for information regarding Holding Time compliance.

Key : CAS Number: Chemical Abstracts Services number is a unique identifier assigned to discrete substances
LOR: Limit of Reporting (detection limit).

Unit	*Description*
-	No Unit
mg/L	milligrams per litre

<: less than.

>: greater than.

Surrogate: An analyte that is similar in behavior to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.

Test results reported relate only to the samples as received by the laboratory.

UNLESS OTHERWISE STATED on SRN or QCI Report, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.

General Comments

The analytical methods used by ALS are developed using internationally recognized reference methods (where available), such as those published by US EPA, APHA Standard Methods, ASTM, ISO, Environment Canada, BC MOE, and Ontario MOE. Refer to the ALS Quality Control Interpretive report (QCI) for applicable references and methodology summaries. Reference methods may incorporate modifications to improve performance.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

Please refer to Quality Control Interpretive report (QCI) for information regarding Holding Time compliance.

Key : CAS Number: Chemical Abstracts Services number is a unique identifier assigned to discrete substances
LOR: Limit of Reporting (detection limit).

Unit	*Description*
-	No Unit
mg/L	milligrams per litre

<: less than.

>: greater than.

Surrogate: An analyte that is similar in behavior to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.

Test results reported relate only to the samples as received by the laboratory.

UNLESS OTHERWISE STATED on SRN or QCI Report, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.

LC = Lethal Concentration, IC = Inhibition Concentration, CL = Confidence Limits
*Hardness-adjusted to approximately 70 mg/L $CaCO_3$

1.0 INTRODUCTION

Nautilus Environmental Company Inc. (Nautilus) conducted toxicity tests on behalf of Pretivm Resources Inc. (Pretivm) to evaluate the toxicity of copper (Cu) in site water and laboratory water. Tests were performed using *Ceriodaphnia dubia*, *Pseudokirchneriella subcapitata*, *Lemna minor* and *Chironomus dilutus* at the Nautilus laboratory in Burnaby, BC. For each species, a test was conducted in both site water identified as BJ-3.10, and in laboratory water with a hardness of approximately 70 mg/L $CaCO_3$, to compare the toxicity of copper.

The results of the toxicity tests are presented in this report. Copies of laboratory data sheets and statistical analyses for the tests are provided in Appendices A through D. The results of analytical chemistry are provided in Appendix E. The chain-of-custody form is provided in Appendix F.

2.0 METHODS

The site water was collected by Pretivm staff on January 10, 2022 in five 20-L carboys and delivered to the Nautilus laboratory on January 13, 2022. The sample was received at a temperature ranging from 10.6 to 11.3°C. Methods for the toxicity tests are summarized in Tables 1 through 4. Testing was conducted according to procedures described by Environment Canada (1997 and 2007a, b, c). A stock solution of 106 mg/L Cu added as copper chloride ($CuCl_2$) was used for preparation of the highest concentration for each test and more dilute test solutions were prepared using half-series dilutions.

Subsamples were collected in plastic HDPE bottles for each concentration at test initiation at test termination for measurement of total and dissolved copper. Laboratory control water and site water BJ-3.10 were also analyzed for hardness, total dissolved and suspended solids, major anions, nutrients and total and dissolved metals. Subsamples were analyzed by ALS Environmental (Burnaby, BC); results are provided in Appendix E.

Statistical analyses for the tests were performed using CETIS (Tidepool Scientific Software, 2013). As per client specification (Robert Goldblatt, pers comm.), average measured dissolved copper concentrations from test initiation and termination were used for statistical analyses, with the exception of the algal test in which measurements were only taken at test initiation; analytical values that were below detection limits were interpreted as half the detection limit value.

Table 1. Summary of test conditions: *Ceriodaphnia dubia* survival and reproduction test.

Test species	*Ceriodaphnia dubia*
Organism source	In-house culture
Organism age	<24 hour old neonates, produced within a 12 hour window
Test type	Static-renewal
Test duration	7 ± 1 day
Test vessel	20-mL glass test tube
Test volume	15 mL
Test solution depth	10 cm
Test concentrations	Seven concentrations, plus laboratory control
Test replicates	10 per treatment
Number of organisms	1 per replicate
Control water	20% Perrier diluted with deionized water to hardness of ~70 mg/L
Test solution renewal	Daily (100% renewal)
Test temperature	25 ± 1°C
Feeding	Daily with *Pseudokirchneriella subcapitata* and TCC[1] (3:1 ratio)
Light intensity	100 to 600 lux at water surface
Photoperiod	16 hours light / 8 hours dark
Aeration	None
Test measurements	Temperature, dissolved oxygen, pH and conductivity measured daily; hardness and alkalinity of undiluted sample measured at test initiation; survival and reproduction checked daily
Test protocol	Environment Canada (2007a), EPS 1/RM/21
Statistical software	CETIS Version 2.1.1
Test endpoints	Survival and reproduction
Test acceptability criteria for controls	≥80% survival; ≥15 young per surviving control producing three broods; ≥60% of controls producing three or more broods; no ephippia present
Reference toxicant	Sodium chloride (NaCl)

[1] TCC = Trout chow and Cerophyl

Table 2. Summary of test conditions: 72-h *Pseudokirchneriella subcapitata* growth inhibition test.

Test species	*Pseudokirchneriella subcapitata*, strain CPCC #37
Organism source	In-house axenic culture, obtained from Canadian Phycological Culture Center, and originally isolated from Nivelta River, Norway.
Organism age	3-to 7-day old culture in logarithmic growth phase
Test type	Static
Test duration	72 hours
Test vessel	Microplate
Test volume	220 µL
Test concentrations	Seven concentrations, plus laboratory control
Test replicates	4 per treatment; 8 for laboratory control
Number of organisms	10,000 cells/mL
Control water	20% Perrier diluted with deionized water to hardness of ~70 mg/L and supplemented with nutrients
Test solution renewal	None
Test temperature	24 ± 2°C
Feeding	None
Light intensity	3600 to 4400 lux
Photoperiod	24 hours light
Aeration	None
Test measurements	Test area temperature measured daily; temperature and pH measured at test initiation; pH of two control wells measured at test termination
Test protocol	Environment Canada (2007b), EPS 1/RM/25
Statistical software	CETIS Version 2.1.1
Test endpoint	Algal cell growth inhibition
Test acceptability criteria for controls	>16-fold increase in number of algal cells; CV ≤ 20%; no trend when analyzed using Mann-Kendall test
Reference toxicant	Zinc (added as $ZnSO_4$)

Table 3. Summary of test conditions: 7-d *Lemna minor* growth inhibition test.

Test species	*Lemna minor*, strain CPCC# 490
Organism source	In-house axenic culture, obtained from Canadian Phycological Culture Centre, and originally isolated from Wainfleet, Stinking Barn, Niagara Peninsula, Ontario, Canada
Organism age	7- to 10-day old culture
Test type	Static
Test duration	7 days
Test vessel	250-mL glass container
Test volume	100 mL
Test solution depth	4 cm
Test concentrations	Seven concentrations, plus laboratory control
Test replicates	4 per treatment
Number of organisms	Two 3-frond plants per replicate
Control/dilution water	Modified APHA media (deionized water plus 1% of each APHA stock solution A, B and C); 20% Perrier water diluted with deionized water to hardness of ~70 mg/L
Test solution renewal	None
Test temperature	25 ± 2°C
Feeding	None
Light intensity	4000 to 5600 lux
Photoperiod	24 hours light
Aeration	None
Test measurements	Test area temperature measured daily; temperature, pH and conductivity measured in all concentrations at test initiation; dissolved oxygen of highest concentration measured at test initiation; temperature and pH measured at test termination
Test protocol	Environment Canada (2007c), EPS 1/RM/37
Statistical software	CETIS Version 2.1.1
Test endpoints	Number of fronds and dry weight
Test acceptability criterion for controls	≥ 8-fold increase in number of fronds
Reference toxicant	Potassium chloride (KCl)

Table 4. Summary of test conditions: 10-d *Chironomus dilutus* water-only survival and growth test.

Test species	*Chironomus dilutus*
Organism source	Aquatic BioSystems, Fort Collins, CO
Organism age	Third instar
Test type	Static-renewal
Test duration	10 days
Test vessel	375-mL glass container
Test volume	275 mL
Test concentrations	Seven concentrations, plus laboratory/site control
Test replicates	5 per sample
Number of organisms	10 per replicate
Control water	20% Perrier water diluted with deionized water to hardness of ~70 mg/L
Test solution renewal	Three times a week on non-consecutive days
Test temperature	23 ± 1°C
Feeding	6 mg of Tetramin per replicate daily
Light intensity	500 to 1000 lux at water surface
Photoperiod	16 hours light/8 hours dark
Aeration	None, unless dissolved oxygen falls below 40% saturation
Test measurements	Temperature, dissolved oxygen, pH and conductivity of overlying water measured daily; hardness, alkalinity and total ammonia of overlying water measured at test initiation and termination
Test protocol	Environment Canada (1997), EPS 1/RM/32 (modified)
Statistical software	CETIS Version 2.1.1
Test endpoints	Survival and dry weight
Test acceptability criteria for controls	≥70% survival; ≥0.6 mg/worm dry weight
Reference toxicant	Potassium chloride (KCl)

3.0 RESULTS

Measured concentrations of total copper were close to target nominal concentrations (within 10%) at test initiation for all tests, indicating that the test solutions had been dosed correctly. Dissolved copper at test initiation was similar to total copper with the exception of the *L. minor* growth inhibition test, which had dissolved copper concentrations at approximately 58% of the target concentrations, likely reflecting the interaction of constituents of the media used for this species on solubility of copper. Dissolved copper concentrations measured at test termination were similar to those present at test initiation for the *C. dubia* test, but concentrations declined during exposure in the *L. minor* and *C. dilutus* tests, both of which were static tests with no solution renewals. Copper was not measured at test termination for the *P. subcapitata* test.

Results of the *C. dubia* survival and reproduction tests are summarized in Tables 5 and 6. Adverse effects were observed on survival and reproduction in both laboratory water and site water. The LC50 for survival was 22.5 µg/L Cu in laboratory water and 12.2 µg/L Cu in site water. The IC20 for reproduction was 12.5 µg/L Cu in laboratory water and 5.2 µg/L Cu in site water.

Results of the *P. subcapitata* growth inhibition tests are summarized in Tables 7 and 8. Adverse effects were observed on growth of *P. subcapitata* with IC20 values of 7.4 µg/L Cu in laboratory water and 2.3 µg/L Cu in site water.

Results of the *L. minor* growth inhibition tests are summarized in Tables 9 and 10. Adverse effects were observed on the frond growth and dry weight of *L. minor* with IC20 values of 3.0 and 2.2 µg/L Cu, respectively, in laboratory water, and 2.9 and 3.4 µg/L Cu, respectively, in site water. As noted above, the concentration of dissolved copper measured in solution was lower than total copper measurements, and declined during exposure, resulting in a calculated average dissolved copper concentration that was less than one-quarter of the total copper that was present at test initiation. Thus, the point estimates reported here are lower than they would be if presented on the basis of total copper, or on the basis of the concentration present at test initiation.

Results of the *C. dilutus* survival and growth tests are summarized in Tables 11 and 12. No significant adverse effects were observed on survival or growth in either laboratory water or site water, with LC50 and IC20 values of >32.8 µg/L Cu for laboratory water and >31.0 µg/L Cu for site water.

Table 5. Results of the *Ceriodaphnia dubia* survival and reproduction test conducted in Laboratory Water.

4.0 QA/QC

The health history of the test organisms used in the exposure was acceptable and met the requirements of the Environment Canada protocol. The tests met all control acceptability criteria and water quality parameters remained within ranges specified in the protocol throughout the test.

Due to a shipping delay associated with delivery of the test organisms, the *C. dilutus* test was initiated one week later than the *C. dubia*, *P. subcapitata* and *L. minor* tests. Although the site water was held at the laboratory during this time period, this holding time is unlikely to have influenced the test results, since the site waters was being used as a dilution water in the test, rather than as a sample, and copper was introduced into the sample immediately prior to testing. Otherwise, there were no deviations from the test methodology other than the planned modifications described in Section 2.0. Uncertainty associated with the test is best described by the standard deviation around the mean and/or the confidence intervals around the point estimates.

Results of the reference toxicant tests conducted during the testing program are summarized in Table 13. Results for these tests fell within the range for organism performance of the mean and two standard deviations, based on historical results obtained by the laboratory with this test, with the exception of the *P. subcapitata* test, which had a result that was marginally lower than the two standard deviation range. There was nothing unusual about this test and it is expected that test results fall outside of the two standard deviation range in 5% of cases based on chance alone. Based on the narrow two standard deviation range for this test method and the minor deviation from the range, this was considered to be an acceptable deviation. Thus, the sensitivity of the organisms used in this test was considered to be appropriate. The reference toxicant tests were performed under the same conditions as those used for the sample.

Table 13. Reference toxicant test results.

Test Species	Endpoint	Historical Mean (2 SD Range)	CV (%)	Test Date
C. dubia	Survival (LC50): 2.1 g/L NaCl	2.0 (1.8–2.2) g/L NaCl	5	January 18, 2022
	Reproduction (IC50): 1.8 g/L NaCl	1.7 (1.4–2.2) g/L NaCl	11	
P. subcapitata	Growth (IC50): 25.6 µg/L Zn	32.3 (26.8–38.9) µg/L Zn	9	January 20, 2022
L. minor	Frond count (IC50): 2.9 g/L KCl	3.3 (2.8–3.9) g/L KCl	8	January 12, 2022
C. dilutus	Survival (LC50): 4.5 g/L KCl	5.4 (3.8–7.6) g/L KCl	17	January 21, 2022

SD = Standard Deviation, CV = Coefficient of Variation, LC = Lethal Concentration, IC = Inhibition Concentration

APPENDIX A – *Ceriodaphnia dubia* Toxicity Test Data

Ceriodaphnia dubia Summary Sheet

Client: Lorax/Petrum Resources Inc. Start Date/Time: Jan 14/22 @ 1130h
Work Order No.: 212490 Set up by: JZL

Sample Information:

Sample ID: Cu w lab water
Sample Date: Jan 13/22
Date Received: Jan 13/22
Sample Volume: N/A

Test Validity Criteria:

1) Mean survival of first generation controls is ≥80 %
2) At least 60% of controls have produced three broods within 8 days
3) An average of ≥15 live young produced per surviving female in the control solutions during the first three broods.
4) Invalid if ephippia observed in any control solution at any time.

WQ Ranges:

T (°C) = 25 ± 1; DO (mg/L) = 3.3 to 8.4 ; pH = 6.0 to 8.5

Test Organism Information:

Broodstock No.: BB010522B
Age of young (Day 0): <24-h (within 12-h)
Avg No. young in first 3 broods of previous 7 d: 22
Mortality (%) in previous 7 d: 0
Individual female # used ≥8 young on test day #21-40

NaCl Reference Toxicant Results:

Reference Toxicant ID: Cd298
Stock Solution ID: 21Na03
Date Initiated: Jan 18/22

7-d LC50 (95% CL): 2.1 (1.5-3.0) g/L NaCL
7-d IC50 (95% CL): 1.8 (1.5-2.0) g/L NaCL

7-d LC50 Reference Toxicant Mean and Historical Range: 2.0 (1.8-2.2) g/L NaCL CV (%): 5
7-d IC50 Reference Toxicant Mean and Historical Range: 1.7 (1.4-2.2) g/L NaCL CV (%): 11

Test Results:
(measured values)

ug/L Cu	Survival	Reproduction
LC50 % (v/v) (95% CL)	22.5 (18.2-27.8)	
IC25 % (v/v) (95% CL)		14.6 (10.6-22.0)
IC50 % (v/v) (95% CL)		23.3 (16.6-27.0)

Ceriodaphnia dubia Summary Sheet

Client: Lorax/Pretivm Resources Inc. Start Date/Time: Jan 14/22 @ 1130L
Work Order No.: 212490 Set up by: JZL

Sample Information:

Sample ID: Cu w site water (B)-3.10
Sample Date: Jan 10 22
Date Received: Jan 13 22
Sample Volume: 5x2 OL

Test Validity Criteria:

1) Mean survival of first generation controls is ≥80 %
2) At least 60% of controls have produced three broods within 8 days
3) An average of ≥15 live young produced per surviving female in the control solutions during the first three broods.
4) Invalid if ephippia observed in any control solution at any time.

WQ Ranges:

T (°C) = 25 ± 1; DO (mg/L) = 3.3 to 8.4 ; pH = 6.0 to 8.5

Test Organism Information:

Broodstock No.: BB010522B
Age of young (Day 0): <24-h (within 12-h)
Avg No. young in first 3 broods of previous 7 d: 22
Mortality (%) in previous 7 d: 0
Individual female # used ≥8 young on test day #21-40

NaCl Reference Toxicant Results:

Reference Toxicant ID: Cd298
Stock Solution ID: 21Na03
Date Initiated: Jan 18/22

7-d LC50 (95% CL): 2.1 (1.5-3.0) g/L NaCL
7-d IC50 (95% CL): 1.8 (1.5-2.0) g/L NaCL

7-d LC50 Reference Toxicant Mean and Historical Range: 2.0 (1.8-2.2) g/L NaCL CV (%): 5
7-d IC50 Reference Toxicant Mean and Historical Range: 1.7 (1.4-2.2) g/L NaCL CV (%): 11

Test Results:
(measured values)

ug/L Cu	Survival	Reproduction
LC50 % (v/v) (95% CL)	12.2 (8.6-17.4)	
IC25 % (v/v) (95% CL)		6.2 (3.7-10.4)
IC50 % (v/v) (95% CL)		10.9 (7.3-13.3)

APPENDIX B – *Pseudokirchneriella subcapitata* Toxicity Test Data

Pseudokirchneriella subcapitata Summary Sheet

Client: Lorax / Pretium Resources Inc.
Work Order No.: 212492

Start Date: Jan 13/22 @ 1630h
Set up by: SAK

Sample Information:

Sample ID: Cu in site water (BJ-3.10)
Sample Date: Jan 10/22
Date Received: Jan 13/22
Sample Volume: 5 x 20L

Test Organism Information:

Culture Date: Jan 7/22
Age of culture (Day 0): 6d

Zinc Reference Toxicant Results:

Reference Toxicant ID: SC224
Stock Solution ID: 21Zn01
Date Initiated: Jan 20/22

72-h IC50 (95% CL): 25.6 (22.8 - 28.7) µg/L Zn

72-h IC50 Reference Toxicant Mean and Range: 32.3 (26.8 - 38.9) µg/L Zn CV (%): 9

Test Results: (measured values)

µg/L Cu	Algal Growth
IC25 %(v/v) (95% CL)	2.7 (2.2 - 4.0)
IC50 %(v/v) (95% CL)	16.6 (14.7 - 18.0)

APPENDIX C – *Lemna minor* Toxicity Test Data

Lemna minor Summary Sheet

Client: Lorax/Pretivm Resources Inc. Start Date: Jan 14/22
Work Order No.: 212491 Set up by: GJU

Sample Information:

Sample ID: Cu in lab control (20% Perrier)
Sample Date: Jan 13/22
Date Received: Jan 13/22
Sample Volume: N/A

Test Organism Information:

Culture Date: Jan 5/22
Age of culture (Day 0): 9 days
>8X growth in APHA?: yes (63 fronds)

KCl Reference Toxicant Results:

Reference Toxicant ID: LM215
Date Initiated: Jan 12/22

7-d No. of Fronds IC50 (95% CL): 2.9(2.7-3.1) g/L KCl

7-d No. Fronds IC50 Reference Toxicant Mean (2 SD Range): 3.3(2.8-3.9) g/L KCl CV (%): 8

Test Results: (measured values)

µg/L Cu	Number of Fronds	Dry Weight
IC25 ~~%(v/v)~~ (95% CL)	3.8(2.8-4.9)	3.3(2.3-4.5)
IC50 ~~%(v/v)~~ mod (95% CL)	>9.69	>9.69

APPENDIX D – *Chironomus dilutus* Toxicity Test Data

Chironomus dilutus Water-only Test Summary Sheet

Client: Lorax/Pretium Resources Inc.
Work Order No.: 212489

Start Date: Jan 21/22
Set up by: JZL/KJL/DK

Sample Information:

Sample ID: Cu in Lab Water
Sample Date: Jan 20/22
Date Received: Jan 20/22
Sample Volume: N/A

Test Organism Information:

Species: *C. dilutus*
Supplier: Aquatic Biosystems, CO
Date received: Jan 19/22
Age or size (Day 0): 3rd in-star

KCl Reference Toxicant Results:

Reference Toxicant ID: CT106
Stock Solution ID: n/a
Date Initiated: Jan 21/22

96-h LC50 (95% CL): 4.5 (3.3-6.3) g/L KCl

96-h LC50 Reference Toxicant Mean and Range: 5.4 (3.8-7.6) g/L KCl CV (%): 17

Test Results:

APPENDIX E – Analytical Chemistry

ALS Environmental

CERTIFICATE OF ANALYSIS

Work Order	: **VA22A1330**	Page	: 1 of 20
Client	: **Nautilus Environmental Company Inc.**	Laboratory	: Vancouver - Environmental
Contact	: Mikayla Oldach	Account Manager	: Emmanuel Mariano
Address	: 8664 Commerce Court Imperial Square Lake City Burnaby BC Canada V5A 4N7	Address	: 8081 Lougheed Highway Burnaby BC Canada V5A 1W9
Telephone	: ----	Telephone	: +1 604 253 4188
Project	: ----	Date Samples Received	: 24-Jan-2022 17:30
PO	: 2022-0220	Date Analysis Commenced	: 25-Jan-2022
C-O-C number	: ----	Issue Date	: 03-Feb-2022 14:31
Sampler	: ----		
Site	: Tissue, Water and Sediment Testing		
Quote number	: Q69439 (Vancouver Blanket Quote)		
No. of samples received	: 86		
No. of samples analysed	: 86		

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted. This document shall not be reproduced, except in full.

This Certificate of Analysis contains the following information:

- General Comments
- Analytical Results

Additional information pertinent to this report will be found in the following separate attachments: Quality Control Report, QC Interpretive report to assist with Quality Review and Sample Receipt Notification (SRN).

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is conducted in accordance with US FDA 21 CFR Part 11.

Signatories	*Position*	*Laboratory Department*
Ilnaz Badbezanchi	Team Leader - Metals preparation	Metals, Burnaby, British Columbia
Kevin Duarte	Supervisor - Metals ICP Instrumentation	Metals, Burnaby, British Columbia
Lindsay Gung	Supervisor - Water Chemistry	Inorganics, Burnaby, British Columbia
Robin Weeks	Team Leader - Metals	Metals, Burnaby, British Columbia
Ruby Pham	Lab Assistant	Metals, Burnaby, British Columbia

General Comments

The analytical methods used by ALS are developed using internationally recognized reference methods (where available), such as those published by US EPA, APHA Standard Methods, ASTM, ISO, Environment Canada, BC MOE, and Ontario MOE. Refer to the ALS Quality Control Interpretive report (QCI) for applicable references and methodology summaries. Reference methods may incorporate modifications to improve performance.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

Please refer to Quality Control Interpretive report (QCI) for information regarding Holding Time compliance.

Key : CAS Number: Chemical Abstracts Services number is a unique identifier assigned to discrete substances
LOR: Limit of Reporting (detection limit).

Unit	*Description*
-	No Unit
µS/cm	Microsiemens per centimetre
mg/L	milligrams per litre
NTU	nephelometric turbidity units
pH units	pH units

<: less than.

>: greater than.

Surrogate: An analyte that is similar in behavior to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.

Test results reported relate only to the samples as received by the laboratory.

UNLESS OTHERWISE STATED on SRN or QCI Report, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.

QUALITY CONTROL INTERPRETIVE REPORT

Work Order	: **VA22A1330**	Page	: 1 of 31
Client	: **Nautilus Environmental Company Inc.**	Laboratory	: Vancouver - Environmental
Contact	: Mikayla Oldach	Account Manager	: Emmanuel Mariano
Address	: 8664 Commerce Court Imperial Square Lake City Burnaby BC Canada V5A 4N7	Address	: 8081 Lougheed Highway Burnaby, British Columbia Canada V5A 1W9
Telephone	: ----	Telephone	: +1 604 253 4188
Project	: ----	Date Samples Received	: 24-Jan-2022 17:30
PO	: 2022-0220	Issue Date	: 03-Feb-2022 14:31
C-O-C number	: ----		
Sampler	: ----		
Site	: Tissue, Water and Sediment Testing		
Quote number	: Q69439 (Vancouver Blanket Quote)		
No. of samples received	: 86		
No. of samples analysed	: 86		

This report is automatically generated by the ALS LIMS (Laboratory Information Management System) through evaluation of Quality Control (QC) results and other QA parameters associated with this submission, and is intended to facilitate rapid data validation by auditors or reviewers. The report highlights any exceptions and outliers to ALS Data Quality Objectives, provides holding time details and exceptions, summarizes QC sample frequencies, and lists applicable methodology references and summaries.

Key

Anonymous: Refers to samples which are not part of this work order, but which formed part of the QC process lot.
CAS Number: Chemical Abstracts Services number is a unique identifier assigned to discrete substances.
DQO: Data Quality Objective.
LOR: Limit of Reporting (detection limit).
RPD: Relative Percent Difference.

Summary of Outliers

Outliers : Quality Control Samples

- No Duplicate outliers occur.
- No Matrix Spike outliers occur.
- Method Blank value outliers occur - please see following pages for full details.
- Laboratory Control Sample (LCS) outliers occur - please see following pages for full details.
- No Test sample Surrogate recovery outliers exist.

Outliers: Reference Material (RM) Samples

- No Reference Material (RM) Sample outliers occur.

Outliers : Analysis Holding Time Compliance (Breaches)

- Analysis Holding Time Outliers exist - please see following pages for full details.

Outliers : Frequency of Quality Control Samples

- Quality Control Sample Frequency Outliers occur - please see following pages for full details.

Outliers : Quality Control Samples

Duplicates, Method Blanks, Laboratory Control Samples and Matrix Spikes

Matrix: **Water**

Analyte Group	Laboratory sample ID	Client/Ref Sample ID	Analyte	CAS Number	Method	Result	Limits	Comment
Method Blank (MB) Values								
Total Metals	QC-398702-001	----	arsenic, total	7440-38-2	E420	0.00133 mg/L B	0.0001 mg/L	Blank result exceeds permitted value

Result Qualifiers

Qualifier	Description
B	*Method Blank exceeds ALS DQO. Associated sample results which are < Limit of Reporting or > 5 times blank level are considered reliable.*

Laboratory Control Sample (LCS) Recoveries								
Total Metals	QC-398664-002	----	thorium, total	7440-29-1	E420	79.0 % MES	80.0-120%	Recovery less than lower control limit

Result Qualifiers

Qualifier	Description
MES	*Data Quality Objective was marginally exceeded (by < 10% absolute) for < 10% of analytes in a Multi-Element Scan / Multi-Parameter Scan (considered acceptable as per OMOE & CCME).*

Analysis Holding Time Compliance

This report summarizes extraction / preparation and analysis times and compares each with ALS recommended holding times, which are selected to meet known provincial and /or federal requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by organizations such as CCME, US EPA, APHA Standard Methods, ASTM, or Environment Canada (where available). Dates and holding times reported below represent the first dates of extraction or analysis. If subsequent tests or dilutions exceeded holding times, qualifiers are added (refer to COA).

If samples are identified below as having been analyzed or extracted outside of recommended holding times, measurement uncertainties may be increased, and this should be taken into consideration when interpreting results.

Where actual sampling date is not provided on the chain of custody, the date of receipt with time at 00:00 is used for calculation purposes.

Where only the sample date without time is provided on the chain of custody, the sampling date at 00:00 is used for calculation purposes.

Legend & Qualifier Definitions

EHTR-FM: Exceeded ALS recommended hold time prior to sample receipt. Field Measurement recommended

EHTR: Exceeded ALS recommended hold time prior to sample receipt.

Rec. HT: ALS recommended hold time (see units).

Quality Control Parameter Frequency Compliance

The following report summarizes the frequency of laboratory QC samples analyzed within the analytical batches (QC lots) in which the submitted samples were processed. The actual frequency should be greater than or equal to the expected frequency.

Matrix: **Water**

Evaluation: ✗ = *QC frequency outside specification*; ✓ = *QC frequency within specification.*

Quality Control Sample Type			Count		Frequency (%)		
Analytical Methods	*Method*	*QC Lot #*	*QC*	*Regular*	*Actual*	*Expected*	*Evaluation*

Methodology References and Summaries

The analytical methods used by ALS are developed using internationally recognized reference methods (where available), such as those published by US EPA, APHA Standard Methods, ASTM, ISO, Environment Canada, BC MOE, and Ontario MOE. Reference methods may incorporate modifications to improve performance (indicated by "mod").

Analytical Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Conductivity in Water	E100 Vancouver - Environmental	Water	APHA 2510 (mod)	Conductivity, also known as Electrical Conductivity (EC) or Specific Conductance, is measured by immersion of a conductivity cell with platinum electrodes into a water sample. Conductivity measurements are temperature-compensated to 25°C.
pH by Meter	E108 Vancouver - Environmental	Water	APHA 4500-H (mod)	pH is determined by potentiometric measurement with a pH electrode, and is conducted at ambient laboratory temperature (normally 20 ± 5°C). For high accuracy test results, pH should be measured in the field within the recommended 15 minute hold time.
Turbidity by Nephelometry	E121 Vancouver - Environmental	Water	APHA 2130 B (mod)	Turbidity is measured by the nephelometric method, by measuring the intensity of light scatter under defined conditions.
TSS by Gravimetry	E160 Vancouver - Environmental	Water	APHA 2540 D (mod)	Total Suspended Solids (TSS) are determined by filtering a sample through a glass fibre filter, following by drying of the filter at 104 ± 1°C, with gravimetric measurement of the filtered solids. Samples containing very high dissolved solid content (i.e. seawaters, brackish waters) may produce a positive bias by this method. Alternate analysis methods are available for these types of samples.
TDS by Gravimetry	E162 Vancouver - Environmental	Water	APHA 2540 C (mod)	Total Dissolved Solids (TDS) are determined by filtering a sample through a glass fibre filter, with evaporation of the filtrate at 180 ± 2°C for 16 hours or to constant weight, with gravimetric measurement of the residue.
Bromide in Water by IC (Low Level)	E235.Br-L Vancouver - Environmental	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
Chloride in Water by IC	E235.Cl Vancouver - Environmental	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
Fluoride in Water by IC	E235.F Vancouver - Environmental	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
Nitrite in Water by IC (Low Level)	E235.NO2-L Vancouver - Environmental	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
Nitrate in Water by IC (Low Level)	E235.NO3-L Vancouver - Environmental	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

Analytical Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Sulfate in Water by IC	E235.SO4 Vancouver - Environmental	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
Ammonia by Fluorescence	E298 Vancouver - Environmental	Water	J. Environ. Monit., 2005, 7, 37-42 (mod)	Ammonia in water is analyzed by flow-injection analysis with fluorescence detection after reaction with orthophthaldialdehyde (OPA).
Total Organic Carbon (Non-Purgeable) by Combustion (Low Level)	E355-L Vancouver - Environmental	Water	APHA 5310 B (mod)	Total Organic Carbon (Non-Purgeable), also known as NPOC (total), is a direct measurement of TOC after an acidified sample has been purged to remove inorganic carbon (IC). Analysis is by high temperature combustion with infrared detection of CO_2. NPOC does not include volatile organic species that are purged off with IC. For samples where the majority of total carbon (TC) is comprised of IC (which is common), this method is more accurate and more reliable than the TOC by subtraction method (i.e. TC minus TIC).
Dissolved Organic Carbon by Combustion (Low Level)	E358-L Vancouver - Environmental	Water	APHA 5310 B (mod)	Dissolved Organic Carbon (Non-Purgeable), also known as NPOC (dissolved), is a direct measurement of DOC after a filtered (0.45 micron) sample has been acidified and purged to remove inorganic carbon (IC). Analysis is by high temperature combustion with infrared detection of CO2. NPOC does not include volatile organic species that are purged off with IC. For samples where the majority of DC (dissolved carbon) is comprised of IC (which is common), this method is more accurate and more reliable than the DOC by subtraction method (i.e. DC minus DIC).
Total Nitrogen by Colourimetry	E366 Vancouver - Environmental	Water	APHA 4500-P J (mod)	Total Nitrogen is determined colourimetrically using a discrete analyzer after heated persulfate digestion of the sample.
Total Phosphorus by Colourimetry (Ultra Trace)	E372-U Vancouver - Environmental	Water	APHA 4500-P E (mod).	Total Phosphorus is determined colourimetrically using a discrete analyzer after heated persulfate digestion of the sample.
Dissolved Orthophosphate by Colourimetry (Ultra Trace Level)	E378-U Vancouver - Environmental	Water	APHA 4500-P F (mod)	Dissolved Orthophosphate is determined colourimetrically on a flow analyzer on a sample that has been lab or field filtered through a 0.45 micron membrane filter. Field filtration is recommended to ensure test results represent conditions at time of sampling.
Total Metals in Water by CRC ICPMS	E420 Vancouver - Environmental	Water	EPA 200.2/6020B (mod)	Water samples are digested with nitric and hydrochloric acids, and analyzed by Collision/Reaction Cell ICPMS. Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.
Dissolved Metals in Water by CRC ICPMS	E421 Vancouver - Environmental	Water	APHA 3030B/EPA 6020B (mod)	Water samples are filtered (0.45 um), preserved with nitric acid, and analyzed by Collision/Reaction Cell ICPMS. Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.

Preparation Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Preparation for Ammonia	EP298 Vancouver - Environmental	Water		Sample preparation for Preserved Nutrients Water Quality Analysis.
Preparation for Total Organic Carbon by Combustion	EP355 Vancouver - Environmental	Water		Preparation for Total Organic Carbon by Combustion
Preparation for Dissolved Organic Carbon for Combustion	EP358 Vancouver - Environmental	Water	APHA 5310 B (mod)	Preparation for Dissolved Organic Carbon
Digestion for Total Nitrogen in water	EP366 Vancouver - Environmental	Water	APHA 4500-P J (mod)	Samples are heated with a persulfate digestion reagent.
Digestion for Total Phosphorus in water	EP372 Vancouver - Environmental	Water	APHA 4500-P E (mod).	Samples are heated with a persulfate digestion reagent.
Dissolved Metals Water Filtration	EP421 Vancouver - Environmental	Water	APHA 3030B	Water samples are filtered (0.45 um), and preserved with HNO3.

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted. This document shall not be reproduced, except in full.

This Certificate of Analysis contains the following information:

- General Comments
- Analytical Results

Additional information pertinent to this report will be found in the following separate attachments: Quality Control Report, QC Interpretive report to assist with Quality Review and Sample Receipt Notification (SRN).

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is conducted in accordance with US FDA 21 CFR Part 11.

Signatories	*Position*	*Laboratory Department*
Angela Ren	Team Leader - Metals	Metals, Burnaby, British Columbia
Angelo Salandanan	Lab Assistant	Metals, Burnaby, British Columbia
Christopher Li	Lab Assistant	Metals, Burnaby, British Columbia
Kim Jensen	Department Manager - Metals	Metals, Burnaby, British Columbia
Lindsay Gung	Supervisor - Water Chemistry	Inorganics, Burnaby, British Columbia
Miles Gropen	Department Manager - Inorganics	Inorganics, Burnaby, British Columbia

General Comments

The analytical methods used by ALS are developed using internationally recognized reference methods (where available), such as those published by US EPA, APHA Standard Methods, ASTM, ISO, Environment Canada, BC MOE, and Ontario MOE. Refer to the ALS Quality Control Interpretive report (QCI) for applicable references and methodology summaries. Reference methods may incorporate modifications to improve performance.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

Please refer to Quality Control Interpretive report (QCI) for information regarding Holding Time compliance.

Key : CAS Number: Chemical Abstracts Services number is a unique identifier assigned to discrete substances
LOR: Limit of Reporting (detection limit).

Unit	*Description*
-	No Unit
µS/cm	Microsiemens per centimetre
mg/L	milligrams per litre
NTU	nephelometric turbidity units
pH units	pH units

<: less than.

>: greater than.

Surrogate: An analyte that is similar in behavior to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.

Test results reported relate only to the samples as received by the laboratory.

UNLESS OTHERWISE STATED on SRN or QCI Report, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.

Qualifiers

Qualifier	*Description*
DLM	*Detection Limit Adjusted due to sample matrix effects (e.g. chemical interference, colour, turbidity).*

QUALITY CONTROL INTERPRETIVE REPORT

Work Order	: **VA22A2340**	Page	: 1 of 25
Client	: **Nautilus Environmental Company Inc.**	Laboratory	: Vancouver - Environmental
Contact	: Mikayla Oldach	Account Manager	: Emmanuel Mariano
Address	: 8664 Commerce Court Imperial Square Lake City Burnaby BC Canada V5A 4N7	Address	: 8081 Lougheed Highway Burnaby, British Columbia Canada V5A 1W9
Telephone	: ----	Telephone	: +1 604 253 4188
Project	: ----	Date Samples Received	: 04-Feb-2022 15:30
PO	: 2022-0220	Issue Date	: 15-Feb-2022 17:11
C-O-C number	: ----		
Sampler	: ----		
Site	: Tissue, Water and Sediment Testing		
Quote number	: Q69439 (Vancouver Blanket Quote)		
No. of samples received	: 45		
No. of samples analysed	: 45		

This report is automatically generated by the ALS LIMS (Laboratory Information Management System) through evaluation of Quality Control (QC) results and other QA parameters associated with this submission, and is intended to facilitate rapid data validation by auditors or reviewers. The report highlights any exceptions and outliers to ALS Data Quality Objectives, provides holding time details and exceptions, summarizes QC sample frequencies, and lists applicable methodology references and summaries.

Key

Anonymous: Refers to samples which are not part of this work order, but which formed part of the QC process lot.
CAS Number: Chemical Abstracts Services number is a unique identifier assigned to discrete substances.
DQO: Data Quality Objective.
LOR: Limit of Reporting (detection limit).
RPD: Relative Percent Difference.

Workorder Comments

Holding times are displayed as "---" if no guidance exists from CCME, Canadian provinces, or broadly recognized international references.

Summary of Outliers

Outliers : Quality Control Samples

- No Method Blank value outliers occur.
- No Duplicate outliers occur.
- No Matrix Spike outliers occur.
- Laboratory Control Sample (LCS) outliers occur - please see following pages for full details.
- No Test sample Surrogate recovery outliers exist.

Outliers: Reference Material (RM) Samples

- No Reference Material (RM) Sample outliers occur.

Outliers : Analysis Holding Time Compliance (Breaches)

- Analysis Holding Time Outliers exist - please see following pages for full details.

Outliers : Frequency of Quality Control Samples

- No Quality Control Sample Frequency Outliers occur.

Outliers : Quality Control Samples

Duplicates, Method Blanks, Laboratory Control Samples and Matrix Spikes

Matrix: **Water**

Analyte Group	Laboratory sample ID	Client/Ref Sample ID	Analyte	CAS Number	Method	Result	Limits	Comment
Laboratory Control Sample (LCS) Recoveries								
Total Metals	QC-407846-002	----	phosphorus, total	7723-14-0	E420	121 % MES	80.0-120%	Recovery greater than upper control limit

Result Qualifiers

Qualifier	*Description*
MES	*Data Quality Objective was marginally exceeded (by < 10% absolute) for < 10% of analytes in a Multi-Element Scan / Multi-Parameter Scan (considered acceptable as per OMOE & CCME).*

Analysis Holding Time Compliance

This report summarizes extraction / preparation and analysis times and compares each with ALS recommended holding times, which are selected to meet known provincial and /or federal requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by organizations such as CCME, US EPA, APHA Standard Methods, ASTM, or Environment Canada (where available). Dates and holding times reported below represent the first dates of extraction or analysis. If subsequent tests or dilutions exceeded holding times, qualifiers are added (refer to COA).

If samples are identified below as having been analyzed or extracted outside of recommended holding times, measurement uncertainties may be increased, and this should be taken into consideration when interpreting results.

Where actual sampling date is not provided on the chain of custody, the date of receipt with time at 00:00 is used for calculation purposes.

Where only the sample date without time is provided on the chain of custody, the sampling date at 00:00 is used for calculation purposes.

Matrix: **Water**

Evaluation: ✗ = Holding time exceedance ; ✓ = Within Holding Time

Legend & Qualifier Definitions

EHTR-FM: Exceeded ALS recommended hold time prior to sample receipt. Field Measurement recommended

EHTR: Exceeded ALS recommended hold time prior to sample receipt.

EHTL: Exceeded ALS recommended hold time prior to analysis. Sample was received less than 24 hours prior to expiry.

Rec. HT: ALS recommended hold time (see units).

Quality Control Parameter Frequency Compliance

The following report summarizes the frequency of laboratory QC samples analyzed within the analytical batches (QC lots) in which the submitted samples were processed. The actual frequency should be greater than or equal to the expected frequency.

Matrix: **Water**

Evaluation: × = *QC frequency outside specification*; ✓ = *QC frequency within specification.*

Quality Control Sample Type			Count		Frequency (%)		
Analytical Methods	*Method*	*QC Lot #*	*QC*	*Regular*	*Actual*	*Expected*	*Evaluation*
Laboratory Duplicates (DUP)							
Alkalinity Species by Titration	E290	405439	1	19	5.2	5.0	✓
Ammonia by Fluorescence	E298	407083	1	12	8.3	5.0	✓
Bromide in Water by IC (Low Level)	E235.Br-L	405445	1	7	14.2	5.0	✓
Chloride in Water by IC	E235.Cl	405444	1	7	14.2	5.0	✓
Conductivity in Water	E100	405441	1	7	14.2	5.0	✓
Dissolved Metals in Water by CRC ICPMS	E421	408190	3	38	7.8	5.0	✓
Dissolved Organic Carbon by Combustion (Low Level)	E358-L	407082	1	6	16.6	5.0	✓

Methodology References and Summaries

The analytical methods used by ALS are developed using internationally recognized reference methods (where available), such as those published by US EPA, APHA Standard Methods, ASTM, ISO, Environment Canada, BC MOE, and Ontario MOE. Reference methods may incorporate modifications to improve performance (indicated by "mod").

Analytical Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Conductivity in Water	E100 Vancouver - Environmental	Water	APHA 2510 (mod)	Conductivity, also known as Electrical Conductivity (EC) or Specific Conductance, is measured by immersion of a conductivity cell with platinum electrodes into a water sample. Conductivity measurements are temperature-compensated to 25°C.
pH by Meter	E108 Vancouver - Environmental	Water	APHA 4500-H (mod)	pH is determined by potentiometric measurement with a pH electrode, and is conducted at ambient laboratory temperature (normally 20 ± 5°C). For high accuracy test results, pH should be measured in the field within the recommended 15 minute hold time.
Turbidity by Nephelometry	E121 Vancouver - Environmental	Water	APHA 2130 B (mod)	Turbidity is measured by the nephelometric method, by measuring the intensity of light scatter under defined conditions.
TSS by Gravimetry	E160 Vancouver - Environmental	Water	APHA 2540 D (mod)	Total Suspended Solids (TSS) are determined by filtering a sample through a glass fibre filter, following by drying of the filter at 104 ± 1°C, with gravimetric measurement of the filtered solids. Samples containing very high dissolved solid content (i.e. seawaters, brackish waters) may produce a positive bias by this method. Alternate analysis methods are available for these types of samples.
TDS by Gravimetry	E162 Vancouver - Environmental	Water	APHA 2540 C (mod)	Total Dissolved Solids (TDS) are determined by filtering a sample through a glass fibre filter, with evaporation of the filtrate at 180 ± 2°C for 16 hours or to constant weight, with gravimetric measurement of the residue.
Bromide in Water by IC (Low Level)	E235.Br-L Vancouver - Environmental	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
Chloride in Water by IC	E235.Cl Vancouver - Environmental	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
Fluoride in Water by IC	E235.F Vancouver - Environmental	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
Nitrite in Water by IC (Low Level)	E235.NO2-L Vancouver - Environmental	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
Nitrate in Water by IC (Low Level)	E235.NO3-L Vancouver - Environmental	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

Analytical Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Sulfate in Water by IC	E235.SO4 Vancouver - Environmental	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
Alkalinity Species by Titration	E290 Vancouver - Environmental	Water	APHA 2320 B (mod)	Total alkalinity is determined by potentiometric titration to a pH 4.5 endpoint. Bicarbonate, carbonate and hydroxide alkalinity are calculated from phenolphthalein alkalinity and total alkalinity values.
Ammonia by Fluorescence	E298 Vancouver - Environmental	Water	J. Environ. Monit., 2005, 7, 37-42 (mod)	Ammonia in water is analyzed by flow-injection analysis with fluorescence detection after reaction with orthophthaldialdehyde (OPA).
Total Organic Carbon (Non-Purgeable) by Combustion (Low Level)	E355-L Vancouver - Environmental	Water	APHA 5310 B (mod)	Total Organic Carbon (Non-Purgeable), also known as NPOC (total), is a direct measurement of TOC after an acidified sample has been purged to remove inorganic carbon (IC). Analysis is by high temperature combustion with infrared detection of CO_2. NPOC does not include volatile organic species that are purged off with IC. For samples where the majority of total carbon (TC) is comprised of IC (which is common), this method is more accurate and more reliable than the TOC by subtraction method (i.e. TC minus TIC).
Dissolved Organic Carbon by Combustion (Low Level)	E358-L Vancouver - Environmental	Water	APHA 5310 B (mod)	Dissolved Organic Carbon (Non-Purgeable), also known as NPOC (dissolved), is a direct measurement of DOC after a filtered (0.45 micron) sample has been acidified and purged to remove inorganic carbon (IC). Analysis is by high temperature combustion with infrared detection of CO_2. NPOC does not include volatile organic species that are purged off with IC. For samples where the majority of DC (dissolved carbon) is comprised of IC (which is common), this method is more accurate and more reliable than the DOC by subtraction method (i.e. DC minus DIC).
Total Nitrogen by Colourimetry	E366 Vancouver - Environmental	Water	APHA 4500-P J (mod)	Total Nitrogen is determined colourimetrically using a discrete analyzer after heated persulfate digestion of the sample.
Total Phosphorus by Colourimetry (Ultra Trace)	E372-U Vancouver - Environmental	Water	APHA 4500-P E (mod).	Total Phosphorus is determined colourimetrically using a discrete analyzer after heated persulfate digestion of the sample.
Dissolved Orthophosphate by Colourimetry (Ultra Trace Level)	E378-U Vancouver - Environmental	Water	APHA 4500-P F (mod)	Dissolved Orthophosphate is determined colourimetrically on a flow analyzer on a sample that has been lab or field filtered through a 0.45 micron membrane filter. Field filtration is recommended to ensure test results represent conditions at time of sampling.
Total Metals in Water by CRC ICPMS	E420 Vancouver - Environmental	Water	EPA 200.2/6020B (mod)	Water samples are digested with nitric and hydrochloric acids, and analyzed by Collision/Reaction Cell ICPMS. Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.

Analytical Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Dissolved Metals in Water by CRC ICPMS	E421 Vancouver - Environmental	Water	APHA 3030B/EPA 6020B (mod)	Water samples are filtered (0.45 um), preserved with nitric acid, and analyzed by Collision/Reaction Cell ICPMS. Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.
Dissolved Hardness (Calculated)	EC100 Vancouver - Environmental	Water	APHA 2340B	"Hardness (as CaCO3), dissolved" is calculated from the sum of dissolved Calcium and Magnesium concentrations, expressed in CaCO3 equivalents. "Total Hardness" refers to the sum of Calcium and Magnesium Hardness. Hardness is normally or preferentially calculated from dissolved Calcium and Magnesium concentrations, because it is a property of water due to dissolved divalent cations.

Preparation Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Preparation for Ammonia	EP298 Vancouver - Environmental	Water		Sample preparation for Preserved Nutrients Water Quality Analysis.
Preparation for Total Organic Carbon by Combustion	EP355 Vancouver - Environmental	Water		Preparation for Total Organic Carbon by Combustion
Preparation for Dissolved Organic Carbon for Combustion	EP358 Vancouver - Environmental	Water	APHA 5310 B (mod)	Preparation for Dissolved Organic Carbon
Digestion for Total Nitrogen in water	EP366 Vancouver - Environmental	Water	APHA 4500-P J (mod)	Samples are heated with a persulfate digestion reagent.
Digestion for Total Phosphorus in water	EP372 Vancouver - Environmental	Water	APHA 4500-P E (mod).	Samples are heated with a persulfate digestion reagent.
Dissolved Metals Water Filtration	EP421 Vancouver - Environmental	Water	APHA 3030B	Water samples are filtered (0.45 um), and preserved with HNO3.

Memo

To	Sylvia Van Zalingen, Newcrest Mining Ltd.
From	Greg Sharam, Brent McMillin, ERM
Date	November 9, 2022
Reference	0642602-003
Subject	Goldwedge Area Lakes Surveys for Waterbirds and Western Toad, July 2022

Dear Ms. Van Zalingen

Newcrest Mining Ltd., Brucejack Mine Division (Brucejack), contracted ERM Consultants Canada Ltd. (ERM) to conduct a field assessment of the Goldwedge area lakes to determine potential effects of water-drawdown on waterbirds and amphibians.

The Goldwedge area lakes are northwest of the Waste Rock and Tailings Storage Facility (WRTSF) in a matrix of exposed rock and recently de-glaciated till, with several small lakes. The area varies between 1,300 m and 1,400 m above sea level and is frequently snow-covered until late in the summer, at the end of July and August. Photo 1 shows the aerial views of the Goldwedge area lakes included in the surveys.

Methods

On July 27 through July 29, 2022, an ERM biologist with experience surveying waterbirds conducted aerial surveys of the Goldwedge area lakes for waterbirds. Aerial surveys followed standard methods developed by the British Columbia (BC) Resource Standards Information Committee (RISC) *Inventory Methods for Waterfowl and Allied Species* (Version 2.0; RIC 1999). The ERM biologist was accompanied by two aerial observers/biologists provided by Brucejack. On July 28, 2022, the ERM biologist conducted a ground survey of the Goldwedge area lakes.

On July 28, 2022, the ERM biologist conducted time-limited ground surveys for amphibians, specifically western toad, using a 15-minute survey period following the protocol described in *Inventory Methods for Pond-breeding Amphibians and Painted Turtle* (Version 2.0; RIC 1998).

Waterbird Results

During the aerial surveys on July 27 through 29, 2022, one unidentified shorebird and eight Canada goose individuals were recorded in the Goldwedge lakes area. The eight Canada geese were present near the same lake each day and are presumed to be the same individuals each day; likely molting and unable to fly. During the ground survey, on July 28, 2022, two waterbird species were recorded: one unidentified sandpiper and three semipalmated plovers. Additionally, a non-waterbird species was recorded: two unidentified ptarmigan fledglings.

Table 1 provides a summary of waterbirds observed during each day of the surveys. Figures 1 to 3 illustrate the survey routes and location of waterbird observations each day.

July 28	Ground	Semipalmated plover	1
July 29	Aerial	Canada goose[1]	8

[1] Eight Canada geese were observed on the same lake each day and presumed to be the same individuals each day; likely molting and unable to fly.

[2] Waypoint not recorded; not displayed on Figure 1.

All species observed are considered common in the area. None of the identified species are listed by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC) or the British Columbia Conservation Data Centre.

Bird Presence in the Goldwedge Ponds

The Goldwedge area lakes have low foraging value for geese, dabbling ducks, and diving ducks in summer and fall. Ice and snow were still present on lakes in late July, and food sources like benthic invertebrates and emergent shoreline vegetation were not conspicuous. Fish are entirely absent, making Goldwedge lakes particularly low in foraging quality for divers. Given the persistent snowpack and poor-quality forage, it is unlikely that geese and ducks are summer residents and are likely only fall transients through the site.

In terms of exposure, the creek appears to support a small number of summer resident Canada geese, who could be on site for 2-2.5 months, consuming food from beside Brucejack Creek. A small number (less than a dozen) dabbling ducks and shorebirds may be summer residents on the creek. Geese, ducks and shorebirds may also stop at the creek during fall migration (the creek is frozen in spring migration), where they may spend between 1-3 days on site.

Shorebirds (resident and transient): Both plovers and sandpipers rely primarily on insects. In the breeding season, sandpipers specialize in insect larvae (Winkler et al. 2020a); plovers consume worms in addition to insects (Winkler et al. 2020b). Both shorebird groups occasionally eat some seeds and/or berries, although during breeding [May–August] and fall migration [June-September] seasons, invertebrates are the most important food items (Davis and Smith 1998). Shorebirds also need invertebrates to fuel their spring migration [April-May]. No shorebirds inhabit interior northern B.C. in the winter [October-April].

Late July could feature two scenarios for shorebirds: breeding residents and fall transients. Residents typically spend roughly three months in the area and rear offspring, meanwhile transients average closer to a four-day stay (Farmer and Durbian 2006).

From a nutritional perspective, the Goldwedge area lakes have poor value for shorebirds. The lakes featured persistent ice and snow at the end of July and did not support visible food sources such as benthic invertebrates that birds from spring, summer, and fall scenarios would require. Given that the lakes still contained ice and snow at the end of July, they were likely frozen at the beginning of June when breeding birds would arrive. Therefore, it is unlikely that shorebirds are using this site as a breeding site and more likely that they are only late fall transients at this location.

Waterfowl (resident and transient): Geese and dabbling ducks are herbivorous, eating both terrestrial and aquatic plants. In the breeding season [May-August], dabblers also consume insects and aquatic invertebrates. Diving ducks are primarily carnivorous; mergansers hunt fish, mollusks, and aquatic invertebrates, however these lakes are not fish bearing and do would not support diving ducks. Submerged vegetation form part of the diet for divers like scaup and others in Genus *Aythya* (Winkler et al. 2020c). Time spent foraging is highest during fall migration [August-October] (Paulus 1988).

Late July would mostly consist of local breeding waterfowl, although early fall migrants are also possible at this time. Nesting birds spend around three months in the vicinity, whereas spring [March-May] and fall transients are represented by shorter stays averaging 28 days (O'Neil et al. 2012). Waterfowl are absent from interior northern B.C. in the winter [October-March].

Amphibian Results

During the ground surveys, on July 28, 2022, no adult amphibians, eggs, or tadpoles of any species were observed.

Overall, the Goldwedge area lakes are poor habitat for western toad, as they are situated between 1,300 m and 1,350 m elevation. Surveys for toad breeding ponds were conducted extensively in the Brucejack Regional Study Area in 2011 and 2012 (Chapter 18 and Appendix 18-A of the Environmental Assessment Certificate Application), and no breeding ponds were located above 900 m elevation. Being above 900 m, the lakes are still frozen in May and early June, during the toad breeding period. The Goldwedge area lakes are routinely frozen until the end of June or early July (Robin McCall, Environmental Manager with Newcrest Mining Ltd., personal communication).

Yours,

Greg Sharam, PhD

Appendix 5-4: WRTSF Best Achievable Technology Assessment

Brucejack Mine: WRTSF Best Achievable Technology Assessment

June 6, 2023

NEWCREST

LORAX ENVIRONMENTAL

PRETIUM RESOURCES INC.

A member of the Newcrest Group of companies

Executive Summary

This report presents a best achievable technology (BAT) assessment for Brucejack Mine. A BAT assessment is a site-specific evaluation of waste control technologies that have been proven in commercial application and whose risks are known, that accounts for any specific operational, environmental, or geographic conditions and economic viability.

This BAT assessment report has been prepared on behalf of Pretium Resources Inc. (Pretium), a member of the Newcrest Group of companies, in support of its application to amend *Mines Act* (MA) Permit M-243 and *Environmental Management Act* (EMA) Effluent Permit 107835 (PE-107835) to allow for an increase to the mine's production rate from 3800 tonnes per day (tpd) to 4950 tpd (4950 tpd Joint Amendments Application). As a result of the increased production rate, concentrations of nitrate, T-Se, D-Cu and T-As at monitoring station BJ 3.10, the mine's regulated discharge compliance location, are predicted to go above BC freshwater aquatic life (FWAL) water quality guidelines or current discharge limits. BJ 3.10 is located at the outlet of the mine's Waste Rock and Tailings Storage Facility (WRTSF), which receives all mine-related discharges. The purpose of this report is to evaluate options for water treatment at the outlet of the WRTSF to meet current discharge limits and applicable water quality guidelines for the proposed increased production scenario.

This BAT assessment has been conducted in accordance with the step-by-step process described in the Ministry of Environment and Climate Change Strategy (ENV) guidance document titled *Best Achievable Technology Assessment to Inform Waste Discharge Standards Handout*, published in October 2021. Treatment technologies for parameters of concern (POCs; *i.e.,* nitrate, T-Se, D-Cu and T-As) during operations were identified and evaluated for feasibility, reliability, control-effectiveness, and cost-effectiveness. Seven technologies were identified for treatment of nitrate, with four deemed feasible and carried forward for further assessment. Six technologies were identified for treatment of T-Se, T-As, and D-Cu, with 2 being deemed feasible for T-Se and D-Cu, and 4 deemed feasible for T-As. The reliability and control-effectiveness evaluations concluded that reverse osmosis (RO) is the most reliable and control-effective technology for all POCs. The most cost-effective technologies in terms of capital and operating cost, respectively, are ion exchange and MBBR for nitrate treatment, RO and nanofiltration (NF) for T-Se and D-Cu treatment, and hydroxide precipitation/co-precipitation and NF for T-As treatment.

Based on the evaluations of feasibility, reliability, and control-effectiveness described in this BAT assessment, it is concluded that the stringent treatment objectives for T-Se and

D-Cu would require the use of RO technology. Although there are alternative treatment options for nitrate (*e.g.*, ion exchange) and T-As (*e.g.*, hydroxide precipitation/co-precipitation with coagulants), RO offers a robust treatment solution for these parameters as well. Therefore, RO is considered best achievable technology to meet the treatment objectives for all POCs, based on the flows and water quality predicted for WRTSF discharge during operations under the proposed increased production rate scenario.

Authorship

This best achievable technology (BAT) assessment was prepared by Lorax Environmental Services Ltd. (Lorax) for Pretium Resources Inc. (Pretium), a member of the Newcrest Group of companies. The report was written by Jane May, B.A.Sc., P.Eng. and Cheng Kuang, M.Sc., RBTech., and reviewed by Alison Shaw, Ph.D., P.Geo. and Patrick Mueller, B.Sc., P.Chem. Lorax Environmental Services Ltd. has relied on information available in scientific literature and information supplied by Pretium and Veolia Water Technologies Canada (Veolia) in preparing this report.

ZVI	Zero Valent Iron

Chemical elements are generally referred to using their one or two letter atomic symbol. Cu denotes copper, for example. A T- or D- preceding the symbol denotes the total or dissolved fraction, respectively (D-Cu, for example). Molecules, functional groups, or polyatomic ions may be referred to either by name (*e.g.*, nitrate) or chemical formula (*e.g.*, NO_3).

1. Introduction

This report presents a best achievable technology (BAT) assessment for treating WRTSF discharge at Brucejack Mine. Brucejack Mine (the mine) is an underground mine operation which is owned and operated by Pretium Resources Inc. (Pretium), a member of the Newcrest Group of companies (Newcrest). The mine is located approximately 60 km NNW of Stewart, British Columbia (BC) and began construction in September 2015, with gold production commencing in July 2017.

A BAT assessment is a site-specific evaluation of waste control technologies that have been proven in commercial application and whose risks are known, that accounts for any specific operational, environmental, or geographic conditions and economic viability. This BAT assessment report has been prepared on behalf of Pretium in support of its application to amend *Mines Act* (MA) Permit M-243 and *Environmental Management Act* (EMA) Effluent Permit 107835 (PE-107835) to allow for an increase to the mine's average daily ore production rate from 3800 tonnes per day (tpd) to 4950 tpd (4950 tpd Joint Amendments Application). Water quality modelling based on the mine plan for the proposed increased production rate predicts that concentrations of certain parameters will go above current water quality discharge limits or BC Freshwater Aquatic Life (FWAL) guidelines at monitoring station BJ 3.10, the mine's regulated discharge location at the outlet to the WRTSF (Lorax, 2023b). Therefore, the purpose of this report is to evaluate options for water treatment at the outlet of the WRTSF to meet current discharge limits and applicable water quality guidelines at BJ 3.10 during operations, under the increased production rate scenario.

1.1 Background

Brucejack Mine is an underground mine operation with related surface infrastructure including a mill, a water treatment plant (WTP), a contact water pond (CWP), a waste rock and tailings storage facility (WRTSF), and a sewage treatment plant (STP). Based on the proposed increased production rate, the total mine operating life is estimated to be 13 years. During the operations phase, mine-related inputs are directed to the WRTSF, including STP effluent, WTP effluent, deposition of potentially acid generating (PAG) waste rock, and deposition of thickened tailings solids and effluent to the bottom of the WRTSF. Monitoring station BJ 3.10 at the WRTSF outlet is the mine's final discharge compliance location where WRTSF discharge limits specified in PE-107835 apply.

Source control is the primary method used to maintain acceptable effluent quality at the WRTSF outlet. Source control strategies are implemented through specific management

plans and associated triggers. For example, the Chromium Management Plan and the Nitrogen Management Plan employ trigger response plans (TRPs) to assess and adjust the management of these parameters. There is also a TRP for the CWP. Similarly, the existing WTP implements process control procedures that are used to adjust treatment based on monitoring results, and relevant discharge management information is described in the Operation, Maintenance and Surveillance (OMS) Manuals for the WRTSF (SRK, 2020a) and Water Management Plan (SRK, 2020b). Monitoring of the various sources of contaminant loadings to the WRTSF, and monitoring of WRTSF effluent at BJ 3.10, show that the source control measures implemented have been effective in maintaining acceptable discharge quality to date.

Site-specific water balance and water quality models have been developed for Brucejack Mine. The water quality model predicts how mining activities at Brucejack Mine will influence water quality in the receiving environment through life of mine (LOM), closure, and into the post-closure phase, considering base case and upper case geochemistry conditions. Water quality predictions are provided for two stations: 1) BJ 3.10, the mine's regulated WRTSF discharge location; and 2) BJ 2.62, a downstream monitoring location in Brucejack Creek which will receive underground mine loads via groundwater pathways once the mine has been flooded following closure.

1.2 Scope

The scope of the BAT assessment is limited to surface treatment at the outlet of the WRTSF (as represented by the BJ 3.10 monitoring station). Treatment within the WRTSF, at surface or at depth, was not evaluated. In addition, the scope of the BAT assessment is limited to active treatment technologies; passive and semi-passive treatment strategies were not considered. Lastly, the BAT assessment identified treatment options for predicted water quality during the operations phase; closure and post-closure water quality conditions were not evaluated.

1.3 Objectives

This report has been prepared in accordance with the guidance document titled *Best Achievable Technology Assessment to Inform Waste Discharge Standards Handout*, published in October 2021 by the Ministry of Environment and Climate Change Strategy (ENV). Therefore, the objectives of this report are to:

1. Identify information to be gathered for the BAT assessment (Section 2.1);
2. Identify all potential technologies or options (Section 2.2);
3. Screen potential technologies for feasible options (Section 2.3);

4. Describe and compare the reliability of each option (Section 2.4);
5. Describe and compare the control-effectiveness of each option (Section 2.5);
6. Describe and compare the cost-effectiveness of each option (Section 2.6); and
7. Select the best achievable technology (Section 2.7).

Conclusions from the BAT assessment are summarized in Section 3.

2. Best Achievable Technology Assessment

This section describes the work conducted to carry out the BAT assessment in accordance with the step-by-step process described in the ENV guidance document titled *Best Achievable Technology Assessment to Inform Waste Discharge Standards Handout*, published in October 2021.

2.1 Identification of Assessment Information

The first step of the BAT assessment process is to identify the information required to conduct the assessment. Design basis information must be defined to identify potential treatment options. Design basis includes modelled flow rates and water quality from the WRTSF (Section 2.1.1 and 2.1.2, respectively), discharge criteria for the treated effluent (Section 2.1.3), and the list of target parameters requiring treatment (Section 2.1.4).

2.1.1 Flow Capacity

A water balance model (WBM) has been developed for Brucejack Mine, which can be used to inform the flow capacity requirements for the treatment of WRTSF waters. The WBM is a detailed interpretation of the mine and water management plans, with consideration of baseline and operational climate, hydrometric, and hydrogeological data collected for the mine site area (*i.e.*, the area that comprises all mine infrastructure within the Brucejack mining leases). Detailed information on the water balance model is presented in Lorax, 2023a.

Based on the WBM, the range of flows expected to report to BJ 3.10 from the WRTSF during the operations phase is approximately 190 to 11,500 m^3/hr, with an average flow rate of 1,878 m^3/hr (Lorax, 2023a). For the purposes of this BAT assessment, the design flow rate for the conceptual WRTSF treatment system is 5,760 m^3/hr, which exceeds the predicted average flow rate at BJ 3.10 by a factor of 3 to accommodate treatment during higher-flow periods.

If the design flow rate for the treatment system is less than the predicted peak flow rate (as it is for the purposes of this BAT assessment), there will be periods in which WRTSF waters bypass the treatment system. Based on feedback obtained through treatment vendor engagement, it is understood that treating 100% of the WRTSF outlet year-round would be impractical and uneconomical, due to the wide range of flows and the significant peak flow rates predicted by the WBM. Additionally, WQM predictions indicate that POC concentrations in the effluent are reduced during freshet when flow is highest (Lorax

2023b). If detailed design for the conceptual BAT treatment system is advanced, a modelling analysis of the predicted flow rates at the WRTSF outlet should be conducted to confirm the optimal design flow rate for the treatment system, recognizing that it may not be necessary to treat 100% of the flow from the WRTSF to achieve compliance at BJ 3.10, depending on flow conditions throughout the year.

2.1.2 Influent Water Quality

As noted above, a water quality model has been developed to generate water quality predictions for Brucejack Mine (Lorax, 2023b). The Brucejack Mine water quality model employs a mass balance approach that accounts for background water quality and runoff volumes reporting from undisturbed portions of the Brucejack Creek watershed, as well as chemical loads emanating from mine sources and water management structures, the WTP, and the STP. Each component of the existing environment and mine site area that may contribute to water quality at the outlet to the WRTSF (BJ 3.10) has been included in the water quality model.

For each monitoring site, water quality predictions are presented for two cases. The Base Case is considered to represent a conservative expected case; whereas the Upper Case incorporates the combined effects of upper case geochemical source terms for all inputs. The Upper Case source terms are generally based on 90th percentile values from geochemical or water quality monitoring datasets for all mine-related flows and employs highly conservative assumptions with respect to both contact water chemistry and onset of acidity. Detailed information on the water quality model is presented in Lorax, 2023b.

Monitoring station BJ 3.10 is located at the WRTSF outlet, with immediate change from effluent to aquatic receiving environment occurring at/within the BJ 3.10 weir structure (*i.e.*, there is no dilution zone for WRTSF effluent). Therefore, water quality predictions at BJ 3.10 represent the anticipated influent concentrations to the selected BAT system. Water quality predictions indicate that treatment at the WRTSF outlet will not be required for the closure and post-closure phases, so only operations phase predictions are considered in this assessment. Maximum modelled values for the operations phase are presented in Table 2-1 below. Measured and modelled concentrations at BJ 3.10 decrease during spring freshet; therefore, treatment to meet discharge limits is less likely to be required during spring.

Table 2-1:
Predicted water quality at BJ 3.10 for 4950 tpd production rate

Parameter	Units	Maximum Modelled – Operations Phase	
		Base Case	Upper Case
Ammonia (as N)	mg-N/L	3.5	5.7
Nitrite (as N)	mg-N/L	0.13	0.21
Nitrate (as N)	mg-N/L	15.2	24.7
Chloride	mg/L	8.2	18.1
Fluoride	mg/L	0.29	0.52
Sulfate	mg/L	114	298
D-Al	mg/L	0.062	0.202
T-Sb	mg/L	0.020	0.031
T-As	mg/L	0.014	0.026
T-B	mg/L	0.14	0.31
T-Ba	mg/L	0.048	0.065
T-Be	mg/L	0.00003	0.00006
D-Cd	mg/L	0.000012	0.00033
T-Cr	mg/L	0.00040	0.00040
T-Co	mg/L	0.00030	0.00130
D-Cu	mg/L	0.00040	0.00090
D-Fe	mg/L	0.008	0.115
T-Fe	mg/L	0.041	0.140
T-Pb	mg/L	0.0003	0.0086
T-Hg	mg/L	0.000004	0.000013
T-Mn	mg/L	0.24	0.30
T-Mo	mg/L	0.016	0.027
T-Ni	mg/L	0.00047	0.0016
T-Se	mg/L	0.0021	0.0062
T-Ag	mg/L	0.000013	0.000039
T-Tl	mg/L	0.00009	0.00012
T-U	mg/L	0.0006	0.0015
T-Zn	mg/L	0.0021	0.017

2.1.3 Treatment Objectives

Treated effluent criteria are defined for each parameter with a discharge limit and/or a BC FWAL water quality guideline (WQG). For each parameter, the applicable discharge limit or BC WQG is applied as the treatment objective for the selected BAT system. For parameters with both a short-term and long-term BC WQG, the long-term guideline is applied for conservatism. In summary, the treatment objective for each parameter is equivalent to:

- The discharge limit stipulated by PE-107835; or
- For parameters without an established discharge limit, the long-term BC FWAL WQG is applied; or
- For parameters without an established discharge limit or long-term BC FWAL WQG, the short-term BC FWAL WQG is applied.

A summary of treatment objectives is presented in Table 2-2 below.

Table 2-2:
Treatment objectives

Parameter	Units	Treatment Objective
pH	-	6.5-9.0
TSS	mg/L	**30**
Ammonia (as N)	mg-N/L	**4**
Nitrite (as N)	mg-N/L	**0.24**
Nitrate (as N)	mg-N/L	**11.5**
Chloride	mg/L	***150***
Fluoride	mg/L	**0.82**
Sulfate	mg/L	***128***
D-Al	mg/L	***0.050***
T-Sb	mg/L	**0.028**
T-As	mg/L	**0.01**
T-B	mg/L	***1.2***
T-Ba	mg/L	***1.0***
T-Be	mg/L	***0.00013***
D-Cd	mg/L	***0.000083***
T-Cr	mg/L	***0.0010***
T-Co	mg/L	***0.0040***
D-Cu	mg/L	***0.0003***
D-Fe	mg/L	**0.35**
T-Fe	mg/L	**1.7**
T-Pb	mg/L	***0.0039***
T-Hg	mg/L	***0.000020***
T-Mn	mg/L	***0.73***
T-Mo	mg/L	***7.6***
T-Ni	mg/L	***0.025***
T-Se	mg/L	***0.0020***
T-Ag	mg/L	**0.00046**
T-Tl	mg/L	***0.00080***
T-U	mg/L	***0.0085***
T-Zn	mg/L	***0.0075***

Notes:
Hardness-dependent BC WQGs were calculated using the baseline median harness of 28 mg/L as $CaCO_3$ (Lorax, 2023b).
Long-term BC WQGs are shown in ***bold italic*** font.
Short-term BC WQGs are shown in **bold** font.
Effluent discharge limits (per PE-107835) are **shaded in bold grey font**.

2.1.4 Target Parameters

Water quality model results (Lorax, 2023b) were screened to identify parameters of potential concern (POPCs) to aquatic life in the receiving environment. POPCs were identified as parameters that had a Base Case model result that was greater than 80% of a water quality benchmark (either a discharge limit or a BC FWAL guideline for parameters that do not have discharge limits) during any mine phase. Concentrations that are below these benchmarks are considered protective of aquatic life in the receiving environment because discharge limits were developed to be protective of aquatic life without dilution in the receiving environment. The screening of BJ 3.10 water quality model results for the operations phase identified seven POPCs: ammonia (NH_3), nitrate (NO_3), sulfate (SO_4), total arsenic (T-As), dissolved aluminum (D-Al), dissolved copper (D-Cu), and total selenium (T-Se). These POPCs were then evaluated to determine if there are reasons to exclude them from further assessment. Ammonia was excluded from further assessment because it was determined that denitrification in the WRTSF will convert ammonia to nitrate, resulting in ammonia levels well below its discharge limit (denitrification is a biochemical process that was not included in the mass balance water quality model). Dissolved aluminum was excluded from further assessment because it was determined that solubility constraints result in the precipitation of D-Al in the WRTSF, which reduces the concentration of D-Al at the WRTSF outlet to below its POPC benchmark. Sulfate was excluded from further assessment because the Base Case model results are less than the long-term BC FWAL guideline during all mine phases, when the sulfate guideline is calculated using the modelled hardness, instead of the baseline hardness of 28 mg/L used for calculating the POPC screening benchmark for sulfate. Therefore, only nitrate, T-As, D-Cu and T-Se are carried forward as parameters of concern (POCs; *i.e.*, target parameters for the selected BAT system).

2.2 Identification of All Potential Technologies

The second step of the BAT assessment process is to identify all potential treatment options. This section provides an overview of treatment technologies that are commercially available and have the potential to treat one or multiple POCs in mine effluent. Passive treatment systems that rely on natural degradation of contaminants (*e.g.,* cyanide, ammonia) are not practical for Brucejack Mine due to site-specific limitations (*e.g.,* available footprint, cold climate) and have not been considered. Hence, the assessment presented herein specifically evaluates active biological (Section 2.2.1), chemical (Section 2.2.2) and physical (Section 2.2.3) treatment technologies for removal of nitrate, T-Se, D-Cu, and/or T-As. Typical achievable concentrations or removal efficiencies for POCs

are provided where available. Target POCs, treatment requirements, and by-products/wastes generated by each treatment technology are summarized in Table 2-3.

2.2.1 Biological Technologies

Biological treatment technologies rely on naturally-occurring or cultivated microorganisms to degrade, oxidize, or reduce contaminants in wastewater. Biological treatment can be accomplished via suspended growth and attached growth processes. In suspended growth processes, microorganisms are kept in suspension by mixing the wastewater being treated. In attached growth processes, microorganisms are attached as biofilms to inert packing media through which the wastewater flows. Attached growth processes are preferable for the treatment of mine wastewater because biofilms are less susceptible to variations in contaminant loading (due to variation in flow or quality) and temperature. Biofilms are also more compact and generate less sludge than suspended growth processes. Biological technologies that are applicable for the treatment of POCs in mine wastewater are described below.

2.2.1.1 Moving Bed Biofilm Reactor

A moving bed biofilm reactor (MBBR) utilizes an attached growth process to facilitate biological oxidation or reduction of target parameters. The MBBR technology was developed in Norway for nitrogen removal from wastewater (Dale *et al.,* 2015). Since its first introduction in the 1990s, over 750 installations have been completed worldwide. The large surface area afforded by polyethylene carriers in MBBRs is favorable for biofilm development. Reactors can be used to facilitate both aerobic and anoxic processes. In aerobic systems, biofilm carriers are kept in suspension via aeration, whereas mechanical mixers are used in anoxic systems (Figure 2-1; Buecker, 2017).

Anoxic MBBRs have been shown to remove nitrate and T-Se from mine wastewater via reductive processes (Dale *et al.,* 2015). In the absence of oxygen, nitrate is used as a preferable electron acceptor by denitrifying bacteria to support organic carbon oxidation and cellular growth. During this process, nitrate is reduced to inert nitrogen gas, with nitrite generated as an intermediate product. Some denitrifying bacteria can also use Se oxyanions (selenate and selenite) as electron acceptors in the absence of oxygen and nitrate (CH2M Hill, 2010).

The biological reduction of nitrate and Se requires a source of organic carbon (*e.g.,* methanol) to serve as the electron donor, and nutrients (*e.g.,* phosphorus, micronutrients) to support biological function (MEND, 2014). In wastewater with high levels of nitrate, a sufficient amount of organic carbon is required for complete nitrate reduction before Se

reduction can occur (CH2M Hill, 2010). The excess carbon source added to reactors will generate additional biomass that requires downstream solid/liquid separation and disposal.

Figure 2-1: Anoxic moving bed biofilm reactor schematic (Buecker, 2017).

2.2.1.2 Fluidized Bed Reactor

A fluidized bed reactor (FBR) is another configuration of an attached growth biological treatment system. The media that supports biofilm growth needs to be maintained in suspension, similar to the MBBR, except that the flow of water is used to maintain the media in suspension rather than mixing or aeration. In an FBR, solid granular media (typically sand or activated carbon) is forced into suspension and continuous mixing (*i.e.*, fluidized) by the high-velocity influent stream flowing upwards from the bottom of the reactor tank (Figure 2-2). The fluidization process allows complete mixing of the media, which increases the active surface area for attached growth and biomass development. Given the fluidized nature of FBRs, little to no pre-treatment for total suspended solids (TSS) is required (CH2M Hill, 2010). In addition, reactors can run continuously without backwashing.

Figure 2-2: Fluidized bed reactor schematic (Envirogen, 2011).

FBRs are seeded with heterotrophic bacteria that are capable of reducing nitrate and Se under anaerobic conditions (CH2M Hill, 2010). Organic carbon and nutrients are pumped into the reactor to serve as the food source/electron donor and to facilitate microbial growth. Excess biomass that sloughs off the media requires downstream solid/liquid separation and disposal. The biomass is typically non-hazardous but should be stored in anoxic/reducing conditions to ensure that the sequestered Se (as elemental Se or adsorbed selenite) is not remobilized.

The FBR technology is commercially proven for removing nitrate from groundwater (CH2M Hill, 2010). It has also been demonstrated at full scale on mining effluent, but few installations have been in operation for long enough to determine long-term feasibility. The typical achievable concentrations of FBR-based systems reported by mining operations are <0.1 mg-N/L for nitrate, and between 5 and 20 µg/L for T-Se (MEND, 2014).

2.2.1.3 ABMet® System

The Advanced Biological Metals Removal Process (ABMet®) technology (patented by GE Water & Process Technology) is an attached growth process which involves running wastewater through a biologically active filter. The biofilter is loaded with granular activated carbon (GAC) and selected strains of microorganisms that target Se removal (Ali and Shrivastava, 2021). Similar to other attached growth processes, ABMet® treatment systems require a carbon source, nutrient additions, and downstream solid/liquid separation for sludge disposal.

There has been pilot-scale and full-scale applications of the ABMet® technology to remove T-Se to low levels (<5 µg/L; CH2M Hill, 2010). A full-scale installation at a gold mine site in South Dakota was reported to consistently meet discharge criteria for nitrate and Se at an average flow rate of 23 m^3/hr (Maniatis and Adams, 2003). The typical achievable concentrations of ABMet® treatment systems reported by mining operations are <0.1 mg-N/L for nitrate, and <5 µg/L for T-Se (MEND, 2014). The range of design flow rates for full-scale ABMet® installations is 6 to 318 m^3/hr. Given its low hydraulic loading rate and long hydraulic retention time requirements, a large footprint is required for the ABMet® system (CH2M Hill, 2010).

2.2.1.4 Electro-Biochemical Reactor

An electro-biochemical reactor (EBR) is an alternative to conventional bioreactors that use organic carbon and excess nutrients to provide the electrons needed for contaminant removal. The EBR technology (patented by INOTEC Inc.) provides a consistent supply of electrons to microorganisms in the reactor at a low voltage potential (1 to 3 V). The electron supply system is controllable, economical, and robust (Opara *et al.,* 2014). Supplying electrons directly to the reactor also generates significantly less sludge and waste products compared to conventional biological treatment technologies. The EBR technology has been demonstrated at bench-scale and pilot-scale only. An average effluent concentration of 2 mg-N/L for nitrate, and 0.5 µg/L for T-Se was achieved for a EBR system piloted at a coal mine operation in British Columbia (Opara *et al.,* 2014).

2.2.2 Chemical Technologies

Chemical treatment technologies generally utilize precipitation/co-precipitation, adsorption, or ion exchange processes for contaminant removal from wastewater. Precipitation/co-precipitation typically involves pH adjustment and the addition of a coagulant to destabilize and aggregate colloidal particles for enhanced settling ability (USEPA, 2002). Chemical adsorption refers to the immobilization of target ions on the surface of a solid phase. Ion exchange is a process where the target ions are preferentially exchanged for ions of similar charge and size from engineered resins. Applications of specific treatment technologies are described below.

2.2.2.1 Hydroxide Precipitation/Co-Precipitation

Hydroxide precipitation/co-precipitation is a common technology used to neutralize acidity and remove metals from mine wastewater. The precipitation of dissolved metals (*e.g.,* Cu) to form metal hydroxides can be summarized based on the following generic reaction:

$$Me^{x+} + X(OH)^{-} \rightarrow Me(OH)_{x\ (s)}$$

The precipitation process occurs at alkaline pH, and the target pH for optimal removal efficiency is metal-specific. To achieve the desired removal efficiencies for various dissolved metals, reactions can be conducted in series to allow for selective precipitation of metal hydroxides at optimal pH conditions. The precipitated solids are then removed using solid/liquid separation techniques (*e.g.*, gravity sedimentation, clarification). The use of a polymeric flocculant enhances the performance of the subsequent separation process and may be necessary to remove smaller flocs (*i.e.*, a mass formed through the aggregation of fine suspended particles) (USEPA, 2014). The resulting sludge residual typically requires treatment (*e.g.*, dewatering) prior to disposal. A general schematic for a chemical precipitation treatment system is illustrated in Figure 2-3.

Figure 2-3: Model schematic of a chemical precipitation system (adapted from USEPA, 2002).

Quick lime and hydrated lime are commonly used as neutralization agents due to their ability to reach high target pH at relatively low costs, and their coagulating properties (MEND, 2014). In chemical precipitation tanks, iron (Fe) and aluminum (Al) salts are often added as coagulants to agglomerate colloidal particles together and facilitate the formation of surface complexes between metals and precipitates, resulting in further metal removal (*i.e.*, co-precipitation). For example, a coagulant is required for treatment of T-As, which can be removed via adsorption onto the precipitated Fe or Al hydroxides, and possibly via precipitation as ferric or Al arsenate (Robins, 2001; Violante *et al.*, 2007; Lakshmanan *et al.*, 2009). Iron-based coagulants (*e.g.,* ferric sulfate and ferric chloride) are more effective at removing As (as arsenate [As^{5+}]) than their Al-based counterparts (USEPA, 2003). Various factors can affect the removal efficiency of As via precipitative processes,

including reagent dosage, mixing intensity, and pH. Under optimal conditions, hydroxide precipitation/co-precipitation using coagulants is capable of achieving <5 µg/L of As^{5+} in effluent (USEPA, 2003).

Selenium removal can also be achieved via co-precipitation of selenite with ferrihydrite (USEPA, 2014). The optimal pH for Se (as selenite) co-precipitation is between 4 to 6, with removal efficiencies reported to be in the range of 85 to 95% (USEPA, 2014). While selenate may also be co-precipitated with Fe salts, treatment efficiency is reduced by the presence of sulfate. A pilot-scale test using co-precipitation technology showed effective Se removal; however, the study concluded that larger-scale treatment would not be economically feasible (MEND, 2014).

2.2.2.2 Sulfide Precipitation

Sulfide precipitation can be used to treat dissolved metals to low concentrations according to the following generic reactions, where Me^{2+} represents a divalent metal ion (*e.g.,* Cu^{2+}):

$$Me^{2+} + S^{2-} \rightarrow MeS_{(s)}$$

$$Me^{2+} + HS^{-} \rightarrow MeS_{(s)} + H^{+}$$

Sulfide precipitation can also precipitate As^{3+}, but it is not effective for treating As^{5+}. Hence, As^{5+} must first be reduced to As^{3+}, which may be accomplished in biological systems that can support both As^{5+} reduction and sulfide generation. Sulfide precipitation may be used to precipitate As^{3+} according to the following reaction (Littlejohn *et al.*, 2015):

$$3H_2S + 2H_3AsO_3 \rightarrow As_2S_3 + 6H_2O$$

Similarly, the reduction of Se^{6+} to Se^{4+}, and subsequent precipitation of Se^{4+} with sulfide can be used to remove Se from solution according to the following reaction (Geoffroy and Demopoulos 2011; Hageman *et al.,* 2016):

$$2H_2S + SeO_2 \rightarrow SeS_2 + 2H_2O$$

The typical achievable concentrations from sulfide precipitation are reported to be <50 µg/L for As^{3+}, <30 µg/L for T-Cu, and <50 µg/L for T-Se (MEND, 2014). To achieve the desired removal efficiencies for various dissolved metals, reactions can be conducted in series to allow for selective precipitation of metal sulfides at optimal pH conditions. The main advantage of sulfide precipitation over hydroxide precipitation/co-precipitation is the lower quantity of sludge generated from the process, as well as the lower solubility of metal sulfides compared to metals bound to ferric oxyhydroxides. In addition, metal sulfide sludges are generally denser than metal hydroxide sludges and contain less bound water; therefore, it is easier to thicken and dewater than hydroxide sludge (ITRC, 2010; MEND,

2014). However, sulfide precipitation has the potential for generation of excess hydrogen sulfide (H_2S), which may be a safety concern and requires process control and monitoring. Residual sulfide in effluent may also pose a risk of downstream toxicity, sulphate and acidity generation, and oxygen depletion. Therefore, residual sulfide oxidation may be required prior to discharge (*e.g.*, via aeration or hydrogen peroxide) (MEND, 2014).

2.2.2.3 Ion Exchange

Ion exchange is a reversible chemical reaction in which ions held electrostatically on the surface of a solid resin are exchanged (via sorption processes) for target ions of similar charge in a solution. Resins are generated through a polymerization process, with functional groups grafted onto the polymers to selectively uptake ions. Ion exchange is often preceded by other treatment processes to remove suspended solids, organics, and other contaminants that can foul the resins and reduce their effectiveness. As influent passes through the ion exchange column, the target ions are immobilized onto resins, and the functional group associated ions are displaced and released into the effluent.

Ion exchange resins must be periodically regenerated to remove the sorbed contaminants and replenish the exchanged ions, potentially adding significant capital and operating costs. The exchange capacity of a resin degrades over time due to fouling and scale formation; hence, periodic resin replacement is required to achieve consistently low effluent concentrations. The resin and regenerant solutions must be periodically replaced, with spent materials requiring management and disposal. The regenerate solutions contain the target ions at pH and concentrations which are not suitable for discharge, and thus require further treatment via chemical precipitation, evaporation and crystallization, or ZVI adsorption for Se treatment systems (MEND, 2014).

Ion exchange can achieve high removal efficiencies (>90%) for target ions, depending on the selected resin and influent chemistry. Ion exchange resins are reported to achieve effluent concentrations of <5 µg/L for T-As, <30 µg/L for T-Cu, and <10 µg/L for T-Se (MEND, 2014). However, treatment performance is affected by solution pH and abundance of other ions, notably sulfate, which compete for sites on the exchange resin. In mine effluent with high concentrations of sulfate, it can be difficult and costly to achieve high removal efficiencies for the target POCs.

Unlike many other chemical technologies that depend on the reactivity of selenite for Se treatment, anion exchange resins are more effective at removing selenate than selenite (Golder, 2020). Hence, Se removal efficiency via ion exchange can be improved by ferric hydroxide co-precipitation of selenite as a pre-treatment step. BQE Water's Selen-IX™ system combines ion exchange with an electrochemical step to selectively remove selenate while fixing Se into inorganic solid residue (Mohammadi *et al.,* 2016). Pilot-scale

demonstrations of the Selen-IX™ system were shown to remove Se from mine-impacted water to as low as 1 µg/L. The first full-scale Selen-IX™ plant was commissioned at the Kemess Mine in 2019-2020 to meet the Se treatment objective of 2 µg/L under a design flow rate of 270 m^3/hr (BQE Water, 2021). Given the recent implementation of this technology, its long-term feasibility and treatment performance at higher flow capacities is uncertain.

2.2.2.4 Chemical Adsorption

Chemical adsorption is the formation of a thin film of ions or molecules on the surface of a solid phase. Similar to co-precipitation, metal ions form chemical bonds with the reactive surface of solid material. Adsorption technologies use a fixed bed of media (typically packed into a tank) through which wastewater flows. Typical media used include zero valent iron (ZVI), activated carbon, or activated alumina. Contaminants concentrate at the surface of a sorbent, thereby reducing their concentration in the bulk liquid phase. As contaminated water is passed through the media, contaminants are adsorbed from solution onto exposed adsorbent media surfaces. Multiple tanks in series can be used to increase treatment performance (USEPA, 2002; Reinsel, 2015).

Zero valent iron can be used to remove contaminants from solution via chemical reduction and/or surface complexation (Junyapoon, 2005). Treatment systems using ZVI typically consist of media in covered tanks or filter vessels that hold elemental iron. As elemental iron is oxidized to ferrous and ferric iron, nitrate and selenate are reduced to nitrogen gas and insoluble elemental Se, respectively. The produced ferric iron precipitates can subsequently remove Se (as selenite), As, and Cu from solution via chemical adsorption.

The reactive surface area of ZVI media is rapidly depleted and requires frequent replacement. Downstream solid/liquid separation is also required to separate the spent ZVI media from treated effluent. This technology is commonly applied to permeable reactive barriers designed for *in situ* remediation of groundwater with flow rates orders of magnitude lower than surface water systems (MEND, 2014). Hence, the applicability of this technology to treating mine effluents may be limited, depending on flow requirements.

2.2.3 Physical Technologies

2.2.3.1 Reverse Osmosis

Reverse osmosis (RO) is the high-pressure application of influent to selectively permeable membranes that exclude dissolved ions by charge and particle size, generating a concentrated reject stream (on the feed side of the membrane) and a treated effluent stream. Reverse osmosis requires no chemical additions and may be run in either batch or

continuous mode. A main advantage of RO is its ability to achieve high removal efficiencies for parameters with stringent regulatory discharge limits. For example, RO technology has been demonstrated at full-scale to remove Se (selenate or selenite) to <5 µg/L (CH2M Hill, 2010). The RO process is capable of removing over 95% of total dissolved solids (TDS) from the feed influent solution, but the precise removal efficiency is parameter-specific and dependent on feed influent quality (MEND, 2014). The RO permeate is typically lower in pH compared to the influent and is very low TDS and alkalinity. Hence, pH adjustment and potentially re-mineralization (*e.g.,* alkalinity addition) prior to discharge to comply with effluent pH and toxicity requirements (MEND, 2014).

Due to the high operating pressure required to pump solution through the RO membrane, increased chemical loadings require increased pressure to maintain the rate of water flow through the membrane (*i.e.,* flux). Further, adjustment of the operating pressure may be required due to changes in water viscosity associated with temperature variations. Factors affecting membrane filtration performance include pH, temperature, and the presence of certain constituents (*e.g.,* calcium, sulfate), which may cause membrane fouling (USEPA, 2002). Although membrane cleaning can restore treatment performance, the cleaning process can be difficult and costly. To prevent membrane damage/fouling, some form of pre-treatment (*e.g.,* TSS removal at a minimum) is required to prolong the life spans of RO systems. Typically, the RO membranes need to be replaced every 3 to 5 years (MEND, 2014). Pre-filtration can minimize the loading of salt precipitates and suspended solids on the membrane surface, thereby extending run length, improving system hydraulics, and reducing operations and maintenance requirements (USEPA, 2003).

The most significant residual generated from RO is the reject stream, which is high in TDS. Reject management and disposal strategies must be considered in the design of RO systems, which may include evaporation and subsequent disposal of residual salts, or collection and disposal of the reject water (MEND, 2014).

2.2.3.2 Nanofiltration

Nanofiltration (NF) is the pressurized application of influent to a charged, selectively permeable membrane that rejects (by charge and size) multivalent ions but allows the passage of water and monovalent ions. This process generates a low TDS permeate stream and a concentrated, high TDS reject stream. Nanofiltration is a good substitute for RO when the rejection of multivalent ions (*e.g.,* Cu^{2+}) is more important than rejection of monovalent ions (*e.g.,* nitrate), and where lower removal efficiencies are acceptable. Treatment systems based on NF operate at a lower pressure compared to RO. However, ions near the molecular weight cut-off for NF (*e.g.,* selenate, selenite) may pass through a

NF membrane under certain conditions (CH2M Hill, 2010). Therefore, treatment performance for NF may not be as effective as RO.

Nanofiltration can be employed following chemical and physical bulk removal processes as a polishing step to achieve low effluent concentrations, or as a pre-treatment step to generate a lower volume and higher concentration stream to reduce capital cost and removal efficiency of treatment by other means. The NF permeate is low in TDS and alkalinity, and re-mineralization of the permeate stream may be required prior to discharge (MEND, 2014). The reject stream requires further handling for appropriate disposal. This may include evaporation and subsequent disposal of residual salts, or collection and disposal of the reject water.

2.2.4 Summary

Biological technologies available for the treatment of nitrate and T-Se are MBBR, FBR, ABMet®, and EBR systems. Available chemical technologies for treatment of T-Se, D-Cu, T-As and/or nitrate are hydroxide precipitation/co-precipitation, sulfide precipitation, ion exchange, and chemical adsorption. Lastly, physical technologies available for treatment of T-Se, D-Cu, T-As and/or nitrate are RO and NF. Target POCs, treatment requirements, and by-products/waste generation for all identified treatment technologies are summarized in Table 2-3 below.

Table 2-3:
Summary of all potential treatment technologies for target parameters

Treatment Technology	Target POCs	Treatment Requirements	By-Products/Waste Generation
Biological Technologies			
Moving Bed Biofilm Reactor (MBBR)	Nitrate and T-Se	• Pre-treatment (pH adjustment, TSS removal) is required • Mechanical mixers required to keep biofilm carries in suspension • Reagent additions of carbon and nutrients are needed for microbial growth	Excess biomass that sloughs off from the biofilm carriers requires downstream solid/liquid separation and disposal.
Fluidized Bed Reactor (FBR)	Nitrate and T-Se	• Pre-treatment (pH adjustment, TSS removal) is required • Pumps required for fluidization/recirculation (*i.e.*, suspension and mixing) of granular media • Reagent additions of carbon and nutrients are needed for microbial growth	Excess biomass from the granular media requires downstream solid/liquid separation and disposal.
ABMet® System	Nitrate and T-Se	• Pre-treatment (pH adjustment, TSS removal) is required • Reagent additions of carbon and nutrients are needed for microbial growth	Backwater is required to periodically slough off excess biomass, which requires downstream solid/liquid separation and disposal.
Electro-Biochemical Reactor (EBR)	Nitrate and T-Se	• Requires a consistent supply of electrons and nutrient additions to support microbial growth	Biological sludge requires disposal.
Chemical Technologies			
Hydroxide Precipitation/Co-Precipitation	T-Se, D-Cu, and T-As	• Requires additions of iron or aluminum salts as coagulants • pH adjustment may be required to achieve desired removal efficiency • Oxidation of arsenite to arsenate is required for As treatment • Reduction of selenate to selenite is required for Se treatment	Sludge generated by co-precipitation and coagulation requires disposal.
Sulfide Precipitation	T-Se, D-Cu, and T-As	• pH adjustment may be required to achieve desired removal efficiency • Sulfide can be supplied via reagent additions or produced by biological reduction	Metal sulfide sludge requires management and disposal. Potential generation of excess hydrogen sulfide (H_2S) may be a safety concern and requires process control and monitoring. Residual sulfide in treated effluent may cause downstream toxicity, sulphate and acidity generation, and oxygen depletion.
Ion Exchange	Nitrate, T-Se, D-Cu, and T-As	• Requires specialized resins for selective removal of target ions • Pre-treatment (*e.g.*, TSS removal) may be required to prevent fouling and damage of resins	Spent resin needs to be disposed of as solid waste, and the concentrated regenerant stream requires treatment prior to disposal.
Chemical Adsorption	Nitrate, T-Se, D-Cu, and T-As	• Pre-treatment for TSS required to prevent media clogging and fouling • Media required (*e.g.*, ZVI, activated carbon, activated alumina) • Treatment efficiency is temperature and pH dependent	Spent media and hydroxide sludge (for ZVI treatment) require disposal.
Physical Technologies			
Reverse Osmosis (RO)	Nitrate, T-Se, D-Cu, and T-As	• Requires high pressure application of influent to selectively permeable membranes that exclude dissolved solids. • Pre-treatment (*e.g.*, TSS removal) may be required to prevent fouling and damage of membranes	High TDS reject stream requires management and disposal. Permeate may require pH adjustment and re-mineralization prior to discharge.
Nanofiltration (NF)	T-Se, D-Cu, and T-As	• Requires high pressure application of influent to selectively permeable membranes that reject multivalent ions only • Pre-treatment (*e.g.*, TSS removal) may be required to prevent fouling and damage of membranes	High TDS reject stream requires management and disposal. Permeate may require re-mineralization prior to discharge.

2.3 Screening for Feasible Options

The third step of the BAT assessment is to screen potential technologies to eliminate options that are not feasible. This section provides a feasibility screening of all treatment technologies identified in Section 2.2 for each applicable POC. Each treatment technology was screened against the following criteria:

- The ability of the technology to achieve the applicable discharge limit / FWAL guideline;
- Whether the technology is considered "proven" for treatment of mine wastewater at full-scale; and
- Whether the technology has been demonstrated under representative climate conditions.

Consideration was also given to the range of flow rates expected from the WRTSF during the operations phase. Capital and operational costs were not considered for the screening.

The results of the feasibility screening for each POC are presented in Table 2-4 through Table 2-7. Technologies that meet all of the above criteria for at least one of the POCs were carried forward as feasible options. Information sources used in support of screening include grey literature (*e.g.,* technical reports, government documents), secondary (*e.g.,* review papers) and primary (*e.g.,* original research) publications, as well as professional opinions solicited from Veolia Water Technologies Canada, a vendor for industrial water treatment technologies.

2.3.1 Nitrate

Technologies that were carried forward or excluded as feasible options for treating nitrate in mine wastewater discharged from the WRTSF are summarized in Table 2-4 below. Of the seven commercially available technologies for nitrate treatment, four were carried forward as feasible options warranting further evaluation for BAT selection. Specifically, MBBR, FBR, ion exchange, and RO met the feasibility screening criteria, including the ability to achieve the current nitrate discharge limit specified in PE-107835. The remaining technologies were excluded due to inability to accommodate the range of flows expected from the WRTSF during the Operations phase (ABMet®), or lack of full-scale mine water installations (EBR, chemical adsorption).

Table 2-4:
Feasibility screening of potential treatment technologies for nitrate

Treatment Technology	Capable of Achieving Current Discharge Limit for Nitrate (11.5 mg/L)?	Proven for Mining Applications at Full-Scale?	Demonstrated Under Representative Climate Conditions?	Carry Forward as Feasible Option?
Biological Technologies				
Moving Bed Biofilm Reactor (MBBR)	Yes[1]	Yes	Yes, but pre-heating of influent to ≥10°C is required for cold climates for optimal treatment performance	Yes
Fluidized Bed Reactor	Yes[2]	Yes, but limited full-scale applications for mine wastewater treatment	Yes, but pre-heating of influent to ≥10°C is required for cold climates for optimal treatment performance	Yes
ABMet® System	Yes[2]	Yes. Full-scale installations are capable of treating flow rates between 6 and 318 m^3/hr	Yes. GE's process guarantee indicates a lower temperature limit of 5 °C. In cold climates, nutrient dosing may be increased to maintain bacterial activity instead of pre-heating water	No, the range of flow rates afforded by ABMet® cannot accommodate the range of flows expected from the WRTSF during the Operations phase
Electro-Biochemical Reactor (EBR)	Yes[3]	No, bench-scale and pilot-scale demonstrations only	Yes	No, due to lack of full-scale installations
Chemical Technologies				
Ion Exchange	Yes, but treatment performance is highly dependent on the resin selected	Yes	Yes	Yes
Chemical Adsorption	Yes[1]	Yes, but most full-scale installations are designed to treat contaminated groundwater, rather than mine wastewater	Yes	No, due to lack of full-scale installations for mine wastewater
Physical Technologies				
Reverse Osmosis (RO)	Yes, RO is generally able to remove >95% of TDS[2]	Yes, but limited full-scale applications for mine wastewater treatment	Yes	Yes

Notes:

[3] Opara *et al.,* 2014.

2.3.2 Total Selenium

Technologies that were carried forward or excluded as feasible options for treating T-Se in mine effluent discharged from the WRTSF are summarized in Table 2-5. For the purposes of screening treatment options, Se is assumed to be present as selenate at the WRTSF outlet since selenate is the prevalent form of Se in oxygenated surface water (Janz *et al*., 2014).

Of the ten commercially available technologies for Se treatment, two were carried forward as feasible options warranting further evaluation for BAT selection. Specifically, RO and NF met the feasibility screening criteria, including the ability to achieve the long-term BC WQG for T-Se. The remaining technologies were excluded due to inability to reliably achieve the target effluent criteria (*e.g.,* MBBR), or lack of full-scale mine water installations (*e.g.,* EBR).

Table 2-5: Feasibility screening of potential treatment technologies for T-Se

Treatment Technology	Capable of Achieving BC WQG for Total Se (2 µg/L)?	Proven for Mining Applications at Full-Scale?	Demonstrated Under Representative Climate Conditions?	Carry Forward as Feasible Option?
Biological Technologies				
Moving Bed Biofilm Reactor (MBBR)	No[1]	Yes	Yes, but pre-heating of influent to ≥10°C is required for cold climates for optimal treatment performance	No, due to inability to achieve BC WQG of 2 µg/L
Fluidized Bed Reactor	No, achievable Se concentration is reported to range from 5 to 20 µg/L[2]	Yes, but limited full-scale applications for mine wastewater treatment	Yes, but pre-heating of influent to ≥10°C is required for cold climates for optimal treatment performance	No, due to inability to achieve BC WQG of 2 µg/L
ABMet® System	Uncertain, achievable Se concentration is reported to be <5 µg/L[2]	Yes. Full-scale installations are capable of treating flow rates between 6 and 318 m^3/hr.	Yes. GE's process guarantee indicates a lower temperature limit of 5 °C. In cold climates, nutrient dosing may be increased to maintain bacterial activity instead of pre-heating water	No, the range of flow rates afforded by ABMet® cannot accommodate the range of flows expected from the WRTSF during the operations phase
Electro-Biochemical Reactor (EBR)	Yes[3]	No, bench-scale and pilot-scale demonstrations only	Yes	No, due to lack of full-scale installations
Chemical Technologies				
Hydroxide Precipitation/Co-Precipitation	No[1]	Yes	Yes	No, due to inability to achieve BC WQG of 2 µg/L
Sulfide Precipitation	No[1]	Yes	Yes	No, due to inability to achieve BC WQG of 2 µg/L
Ion Exchange (IX)	Traditional IX: No, the abundance of competing ions (*e.g.*, sulfate) in mine effluent has a major impact on Se treatment performance[2] Selen-IX™: Yes[4]	Traditional IX: Yes Selen-IX™: Yes, but very limited full-scale installations. A full-scale plant commissioned in Kemess, BC[4] is capable of removing Se at a design flow rate of 270 m^3/hr	Traditional IX: Yes Selen-IX™: Yes	Traditional IX: No, due to inability to achieve BC WQG of 2 µg/L Selen-IX™: No, due to limited full-scale implementation, particularly at the higher flow rates anticipated at Brucejack Mine
Chemical Adsorption	Unlikely[1]	Yes for ZVI, but most full-scale installations are designed to treat contaminated groundwater, rather than mine wastewater	Yes	No, due to lack of full-scale installations for mine wastewater and uncertain ability to achieve BC WQG of 2 µg/L
Physical Technologies				
Reverse Osmosis (RO)	Yes, RO can achieve 91-99% Se removal[2]	Yes, but limited full-scale applications for mine wastewater treatment	Yes	Yes
Nanofiltration (NF)	Yes, NF can achieve >90% Se removal[2]	Yes, for treating multivalent ions. Limited full-scale applications for mine wastewater treatment	Yes	Yes

2.3.3 Dissolved Copper

Technologies that were carried forward or excluded as feasible options for treating D-Cu in mine effluent discharged from the WRTSF are summarized in Table 2-6. Of the six commercially available technologies for Cu treatment, two were carried forward as feasible options warranting further evaluation for BAT selection. Specifically, RO and NF met the feasibility screening criteria, including the ability to achieve the long-term BC WQG for D-Cu. The remaining technologies were excluded due to inability to reliably achieve the BC WQG for D-Cu.

Table 2-6:
Feasibility screening of potential treatment technologies for D-Cu

Treatment Technology	Capable of Achieving BC WQG for Dissolved Cu (0.3 µg/L)?	Proven for Mining Applications at Full Scale?	Demonstrated Under Representative Climate Conditions?	Carry Forward as Feasible Option?
Chemical Technologies				
Hydroxide Precipitation/Co-Precipitation	No[1]	Yes	Yes	No, due to inability to achieve BC WQG of 0.3 µg/L
Sulfide Precipitation	No[1]	Yes	Yes	No, due to inability to achieve BC WQG of 0.3 µg/L
Ion Exchange	No	Yes	Yes	No, due to inability to achieve BC WQG of 0.3 µg/L
Chemical Adsorption	No[1]	Yes, but most full-scale installations are designed to treat contaminated groundwater, rather than mine wastewater	Yes	No, due to inability to achieve BC WQG of 0.3 µg/L
Physical Technologies				
Reverse Osmosis (RO)	Yes, RO can achieve >95% Cu removal[2]	Yes, but limited full-scale applications for mine wastewater treatment	Yes	Yes
Nanofiltration (NF)	Yes, NF can achieve >90% Cu removal[2]	Yes, for treating multivalent ions, but limited full-scale applications for mine wastewater treatment	Yes	Yes

Notes:
[1] J. Dallaire (Veolia Water Technologies Canada), personal communication, November 29, 2022.
[2] MEND (2014).

2.3.4 Total Arsenic

Technologies that were carried forward or excluded as feasible options for treating T-As in mine effluent discharged from the WRTSF are summarized in Table 2-7. Of the six commercially available technologies for As treatment, four were carried forward as feasible options warranting further evaluation for BAT selection. Specifically, hydroxide precipitation/co-precipitation using Fe/Al coagulants, ion exchange, RO, and NF met the feasibility screening criteria, including the ability to achieve the current T-As discharge limit specified in PE-107835. Sulfide precipitation and chemical adsorption were ruled out due to uncertainty regarding their ability to reliably achieve the T-As discharge limit (as per PE-107835) at BJ 3.10.

Table 2-7:
Feasibility screening of potential treatment technologies for T-As

Treatment Technology	Capable of Achieving Current Discharge Limit for Total As (10 µg/L)?	Proven for Mining Applications at Full Scale?	Demonstrated Under Representative Climate Conditions?	Carry Forward as Feasible Option?
Chemical Technologies				
Hydroxide Precipitation/Co-Precipitation with Coagulants	Yes[1]	Yes	Yes	Yes
Sulfide Precipitation	No[2]	Yes	Yes	No, due to inability to achieve discharge limit of 10 µg/L
Ion Exchange	Yes[3]	Yes	Yes	Yes
Chemical Adsorption	Insufficient information	Yes for ZVI, but most full-scale installations are designed to treat contaminated groundwater, rather than mine wastewater	Yes	No
Physical Technologies				
Reverse Osmosis (RO)	Yes, RO can achieve 91-99% of As^{5+} removal, and 20-55% of As^{3+} removal[3]	Yes, but limited full-scale applications for mine wastewater treatment	Yes	Yes
Nanofiltration (NF)	Yes, NF can achieve >90% of As^{5+} removal, and 20-90% of As^{3+} removal[3]	Yes, for treating multivalent ions. Limited full-scale applications for mine wastewater treatment	Yes	Yes

2.4 Comparison of Reliability

The fourth step of the BAT assessment process is to describe and compare feasible technologies for reliability. Reliability refers to the probability that a technology will operate according to its specifications to perform consistently. Considerations include the ability to maintain treatment performance under variable conditions (*e.g.*, influent water quality, flow rate, temperature) and the intensity of maintenance requirements (*e.g.*, management of scaling, resin replacement). The relative reliability of treatment options carried forward as feasible options for the POCs are discussed and compared in the following subsections. A summary of the relative reliability rankings for each POC is presented in Table 2-8 below, with 1 representing the highest reliability.

Table 2-8:
Reliability rankings for feasible treatment options

Treatment Technology	Relative Reliability Ranking		
	Nitrate	T-Se & D-Cu	T-As
MBBR	3	-	-
FBR	4	-	-
Hydroxide Precipitation/Co-Precipitation with Coagulants	-	-	2
Ion Exchange	2	-	3
RO	1	1	1
NF	-	2	1

2.4.1 Nitrate

The four technologies identified as feasible treatment options for nitrate are MBBR, FBR, ion exchange, and RO. In general, biological treatment systems may suffer from instability due to toxic or inhibitory contaminants (*e.g.,* heavy metals, organics) in influent, making them generally less reliable compared to chemical and physical technologies. Diligent operator attention is required to maintain biological growth and achieve consistent effluent quality from reactors. In contrast, ion exchange and RO systems can achieve consistent treatment performance under a wide range of influent quality and flow conditions; however, resin regeneration (ion exchange) and frequent cleaning (RO) are required (MEND, 2014).

Of the four feasible treatment options identified for nitrate, ion exchange and RO are considered more reliable than biological treatment technologies (MMBR and FBR), primarily because they are less susceptible to variable influent quality, flows, and temperature. FBRs are ranked lower than MBBRs because of the limited number of full-scale installations for mine effluent; whereas, MBBRs are an established technology with

demonstrated long-term feasibility. Ion exchange is ranked lower than RO because it is more sensitive to variations in influent quality and resin selection.

2.4.2 Total Selenium and Dissolved Copper

Two pressure-driven membrane processes (RO and NF) are identified as feasible options for treating T-Se and D-Cu. The main differences between RO and NF are the membranes and operating pressure used for treatment. Given the smaller pore size of RO membranes, RO is considered more reliable than NF for consistent achievement of the stringent treatment objectives, particularly for target ions near the molecular weight cut-off for NF membranes (*e.g.,* selenate, selenite; CH2M Hill, 2010).

2.4.3 Total Arsenic

The four technologies identified as feasible options for treating T-As are hydroxide precipitation/co-precipitation with coagulants, ion exchange, RO, and NF. The treatment requirements discussed for ion exchange systems (Section 2.4.1) and RO and NF processes (Section 2.4.2) are also applicable for As. The RO and NF technologies are considered more reliable than hydroxide precipitation/co-precipitation, as the treatment performance for As via hydroxide precipitation/co-precipitation is dependent on the type and dosage of coagulants used, mixing intensity, and pH (USEPA, 2003). However, these operating parameters can be well-controlled. In contrast, the treatment performance of ion exchange depends on the influent quality (*i.e.*, the presence of competing ions), which is more difficult to maintain via process control. Therefore, ion exchange is considered the least reliable treatment technology for T-As, whereas RO and NF are considered the most reliable.

2.5 Comparison of Control-Effectiveness

The fifth step of the BAT assessment is to describe and compare feasible technologies for control-effectiveness. Control-effectiveness describes how well a control (*e.g.,* treatment technology) is at reducing or managing the risk it is meant to modify (*i.e.*, treatment effectiveness to avoid environmental contamination). The relative control effectiveness of feasible treatment options identified for POCs are discussed and compared based on their ability to achieve successful control of POC concentrations in treated effluent. Secondary consideration is also given to energy requirements and generation of waste products that may pose unintended risks to the downstream environment if not properly managed.

A summary of the relative control-effectiveness rankings for each POC is presented in Table 2-9 below, with 1 representing the highest control-effectiveness.

Table 2-9:
Control-effectiveness rankings for feasible treatment options

Treatment Technology	Relative Control-Effectiveness Ranking		
	Nitrate	T-Se & D-Cu	T-As
MBBR	3	-	-
FBR	3	-	-
Hydroxide Precipitation/Co-Precipitation with Coagulants	-	-	3
Ion Exchange	2	-	4
RO	1	1	1
NF	-	2	2

2.5.1 Nitrate

Treatment systems based on MBBR, FBR, ion exchange, and RO technologies are expected to remove nitrate from mine effluent according to their design specifications. However, the establishment of biological systems (*e.g.,* MBBR, FBR) can take months and cannot be accomplished with influent temperature lower than 10 °C (MEND, 2014). Hence, reactors can only be commissioned during warm seasons, or a water heating system is required to preheat the influent prior to pumping to the reactors. Once microbes are properly seeded and matured, systems can operate under lower temperatures. However, as noted previously, biological processes are generally sensitive to changes in influent water quality, flow, and temperature, which makes system performance more challenging to control. Sludge generated from excess biomass requires solid/liquid separation and disposal. Additionally, any excess nutrients released from the reactors may require further treatment to prevent the risk of eutrophication in the receiving environment.

Unlike biological systems, ion exchange and RO can be operated to achieve consistent effluent quality in a timely and well-controlled manner. Both ion exchange and RO generate a concentrated waste stream that requires management (*i.e.*, treatment and/or disposal). The spent regenerant solutions from ion exchange systems contain target ions (*e.g.,* nitrate) at pH and concentrations that will pose a risk to downstream water quality if not properly managed. Similarly, the high TDS reject stream from RO systems must be managed appropriately. The permeate stream after RO treatment may also require pH adjustment and re-mineralization to meet effluent pH and toxicity requirements (MEND, 2014).

Despite high energy demand and the generation of waste concentrate, RO is considered the most control-effective technology for achieving high removal efficiencies of nitrate. Ion exchange technology also produces a concentrated waste stream, but its control-

effectiveness is subject to variations in influent quality; therefore, it is considered the most control-effective technology after RO. MBBR and FBR systems are considered less control-effective due to their sensitivity to variations in influent quality, flow rate and temperature, and both processes generate biological sludge. Therefore, MBBR and FBR are considered the least control-effective for treatment of nitrate.

2.5.2 Total Selenium and Dissolved Copper

Treatment systems based on RO and NF are expected to achieve consistent effluent quality via pressure-controlled membrane filtration processes. Both RO and NF systems can be automated, with operation performed in a timely and controlled manner. The reject and permeate streams require management, treatment and/or disposal. As discussed in Section 2.4.2, RO is capable of achieving higher removal efficiencies than NF, which may be required to meet the stringent discharge criteria for T-Se and D-Cu. Therefore, RO is ranked higher for control effectiveness compared to NF for the treatment of T-Se and D-Cu.

2.5.3 Total Arsenic

The four technologies identified as feasible options for treating T-As are hydroxide precipitation/co-precipitation with coagulants, ion exchange, RO, and NF. The control effectiveness considerations discussed for ion exchange (Section 2.5.1) and RO and NF (Section 2.5.2) processes are also applicable for As. Treatment systems based on hydroxide precipitation/co-precipitation can be operated in a controlled and timely manner to achieve the target removal efficiency for T-As. The sludge generated from chemical precipitation processes requires disposal, which can typically be accommodated by on-site tailings storage facilities, engineered ponds, open pits, *etc*. (MEND, 2014).

Despite high energy demand and the generation of waste concentrate, RO is considered the most control-effective technology for achieving high removal efficiencies of arsenic. NF is associated with lower energy demand, but also produces a concentrate waste and typically achieves slightly lower removal efficiencies than RO. Hydroxide precipitation/co-precipitation produces sludge (which is easier to manage than the concentrate stream produced by RO and NF), but the removal efficiency of As via hydroxide precipitation/co-precipitation is dependent on the type and dosage of coagulants used, mixing intensity, and pH (USEPA, 2003), so hydroxide precipitation/co-precipitation is considered less control-effective than RO and NF. Ion exchange produces a concentrated waste and its treatment performance depends on the influent quality (*i.e*., the presence of competing ions), which is more difficult to maintain via process control than the operating

parameters for hydroxide precipitation/co-precipitation. Therefore, ion exchange is considered the least control-effective treatment technology for T-As.

2.6 Comparison of Cost-Effectiveness

The sixth step of the BAT assessment process is to describe and compare feasible technologies for cost-effectiveness. This section presents capital and operating cost estimates, as well as an overview of assumptions, limitations, and considerations for comparing cost-effectiveness of the feasible treatment options identified in Section 2.3.

2.6.1 Assumptions and Limitations

Capital and operating cost estimates for each treatment option warranting further evaluation for BAT selection (Section 2.3) are presented in Table 2-10 below. Costs presented in this section are order-of-magnitude (±50%) estimates available in literature (MEND, 2014; *i.e.*, not site-specific for Brucejack Mine), un-adjusted for inflation. Available cost estimates were developed based on a design flow rate of 3000 m^3/hr and a nominal flow rate of 1000 m^3/hr, with the exception of the MBBR technology. Due to limited availability of cost information, the MBBR cost estimates are based on lower design and nominal flow rates (600 m^3/hr and 180 m^3/hr, respectively). However, the MBBR cost estimates have been subsequently scaled up by factors of 5.0 (capital cost) and 5.5 (operating cost) to allow for comparison with the cost estimates for the other technologies. Cost estimates specific to the conceptual WRTSF system at Brucejack Mine are discussed in Section 3.

For most treatment technologies, total installed costs were estimated by applying typical factors to equipment costs to incorporate additional direct and indirect costs. Direct cost factors account for shipping and transportation, installation, site preparation and civil works, piping, HVAC, electrical and controls and plant services and utilities costs. Indirect cost factors account for wrap-around engineering, procurement, construction management, temporary construction services, insurance, spares, and cold commissioning (MEND, 2014).

Actual site costs could vary significantly from the presented estimates, depending on numerous site-specific factors including process factors (*e.g.*, effluent parameters of concern and concentrations, pH, temperature, volume/flow rate) and site factors (*e.g.*, site location, shipping costs, electricity costs, existing effluent management and treatment facilities, existing residuals storage/disposal facilities, site layout, available outdoor footprint, available footprint in process buildings, available utilities, available skilled labour, discharge criteria, *etc.*). Site-specific factors that could have a substantial impact

on total installed cost and operating cost include but are not limited to, the following (MEND, 2014):

- Effluent characteristics, including parameters of concern, concentration, pH, temperature, and ionic strength. These characteristics of the effluent can affect the amounts of reagents required and the amount of sludge or waste products generated which require management and storage.
- Volume or flow rate of the effluent and the seasonal variability of the flow. This can also be influenced by the amount of seasonal attenuation capacity existing on site or that must be added.
- Site location, which can affect materials and equipment transportation costs, reagent shipping costs, and labour costs. Site location may also affect the scheduling of construction and can significantly increase construction costs if construction windows are small or if construction labour needs to be brought to site at a premium, as examples.
- Climatic conditions, which can affect the volumes of effluent to be treated, the available treatment and/or discharge window, the effluent pre-treatment required (*i.e.*, preheating), and the design of residuals storage/disposal facilities.
- Source of electricity supply (grid based, generators) and the resultant electricity costs. It should be noted that the addition of treatment equipment at some sites may require the addition of supplementary power generation equipment, adding significant capital and operating cost to the site.
- Existing effluent management and treatment facilities, their age, effectiveness and capacity.
- Existing residuals storage/disposal facilities. Cost of residual disposal may be significantly increased if new storage/disposal cells or facilities are needed, storage capacity must be augmented to handle new volumes of waste, and/or regulatory approvals must be sought for these new facilities.
- Existing site layout. Distances to transport residuals to storage/disposal facilities, either by pipeline or by trucking can affect operating as well as initial capital costs. Site layout may also affect the cost of supplying utilities to the effluent treatment plant.
- Footprint availability. The availability of land on site, or space within existing process buildings, can impact costs in a variety of ways. Additional buildings may need to be constructed or demolition activities may need to occur.

- Soil qualities and geotechnical characteristics in the area of the mine operations directly impact the cost of construction of any new buildings or structures required for the treatment plant.
- Available service utilities, such as potable water or other special quality water, natural gas, steam, *etc*.
- Available skilled labour, especially labour familiar with the operation of specialty effluent treatment equipment (*e.g*., MBBR, RO, *etc*.). The regional cost differences in labour rates can also affect operating costs and construction costs significantly.
- Test work requirements that can include both bench and pilot testing. These test programs must be conducted before many of the technologies can be implemented at full scale, adding additional costs to the estimate and potentially delaying schedule for implementation.
- Local permitting requirements and stakeholder consultation requirements, which can significantly affect schedule, as well as cost.

Specific assumptions and cost considerations for each technology are described below.

2.6.1.1 Cost Considerations for Feasible Technologies

Capital and operating cost estimates for each of the feasible technology options are summarized in Table 2-10 and discussed below.

Table 2-10:
Capital and operating cost estimates for feasible treatment options

Treatment Technology	Applicable Target Parameters				Equipment Cost ($CAD)	Total Installed Cost ($CAD)	Annual Operating Cost ($CAD/yr)	Operating Cost per Volume ($CAD/m^3)
	NO_3	Se	As	Cu				
MBBR	✓	-	-	-	37,000,000	$98,000,000	$5,225,000	0.60
FBR	✓	-	-	-	n/a	$164,000,000	$14,000,000	0.85 to 1.59
Hydroxide Precipitation/ Co-Precipitation	-	-	✓	-	n/a	$58,600,000 to $72,700,000	$24,300,000 to $30,900,000	2.78 to 3.53
Ion Exchange	✓	-	✓	-	$29,600,000	$76,400,000	$7,400,000	0.85
RO	✓	✓	✓	✓	$49,500,000	$177,300,000	$8,400,000	0.96
NF	-	✓	✓	✓	$49,500,000	$177,300,000	$6,900,000	0.79

Notes:
Cost estimates are adapted from MEND, 2014.
Cost estimates are based on a design flow rate of 3000 m^3/hr and a nominal flow rate of 1000 m^3/hr, with the exception of MBBR. Cost estimates for MBBR were not available at these flow rates, so available capital and operating cost estimates for MBBR technology have been scaled up by factors of 5.0 (based on a design flow rate of 600 m^3/hr) and 5.5 (based on a nominal flow rate of 180 m^3/h), respectively, to allow for comparison with the other technologies presented. Scaling calculations assume the capital cost estimates are based on the design flow rate, and the operating cost estimates are based on the nominal flow rate.
n/a = not available.

Capital investment for MBBR technology is low compared to most other attached growth and suspended growth biological processes. The cost estimates account for pre-heating and heat recovery, assuming a temperature rise of 5°C is required year-round. Capital cost estimates assume that existing chemical make-up, storage, and distribution systems can be utilized for pH adjustment. Operating cost will vary based on reagent consumption (*e.g.*, pH adjustment chemicals, coagulants), which is proportional to contaminant loading, feed pH, and treated effluent limits. Residual biomass typically requires thickening and dewatering prior to disposal; residuals management and storage of biomass residuals has not been considered (MEND, 2014).

FBR technology requires equipment associated with reagent storage and dosing, an influent heat exchange system, the biological reactors, aerobic polishing, and solid/liquid separation and/or sludge handling, thickening and disposal. Due to the relatively recent adoption of this technology, little is known about the long-term stability of residual biomass and the potential for contaminant remobilization under various disposal conditions. If residuals are not stable, significant costs associated with biomass stabilization technology or re-treatment of residual leachate could be incurred (MEND, 2014).

Hydroxide precipitation/co-precipitation technology requires equipment for reagent make-up/storage and feed systems, agitated reaction tank(s), pH adjustment tanks, clarifier/thickener(s) and/or media filter(s), and residuals management. If residuals are not kept stable through prudent disposal techniques, significant costs associated with residuals stabilization technology or re-treatment of residual leachate could be incurred. Operating cost will vary based on reagent consumption (*e.g.*, pH adjustment chemicals, coagulants), which is proportional to contaminant loading, feed pH, and treated effluent limits (MEND, 2014).

Ion exchange requires pre-treatment clarification and media filtration steps for solids removal; therefore, cost estimates account for equipment associated with these systems. Depending on effluent chemistry, additional pre-treatment could add additional operating cost. The cost estimates assume that backwash from media filtration is directed to a settling pond. Regenerant management must be carefully considered based on site-specific factors and could add significant operating and capital costs. Spent resin disposal costs are not accounted for; off-site disposal would add to operating costs. Furthermore, operating costs for ion exchange systems are extremely sensitive to metal loading in the feed stream (MEND, 2014).

Cost estimates for the RO treatment option include clarification and media filtration for solids removal, which is also required pre-treatment for the reverse osmosis system.

Depending on effluent chemistry, additional pre-treatment, post-treatment, and membrane cleaning requirements could add additional capital and operating cost. The available cost estimates do not include management, treatment and/or disposal of the RO concentrate stream, which will likely add significant capital and operating cost. The operating cost for the RO system is highly dependent on the site-specific energy cost and on the required frequency of cleaning cycles, which is dependent the RO feed quality. Further, RO permeate is very low in TDS and alkalinity, so re-mineralization or pH adjustment of the permeate stream prior to discharge to the environment may be required to comply with treatment objectives (MEND, 2014).

Due to the similarities between NF and RO (with the exception of operating pressure and membranes), the capital costs for NF are assumed to be the same as estimated for reverse osmosis. NF operates at lower pressures compared to reverse osmosis; therefore, energy consumption for nanofiltration is assumed to be 2/3 of the energy requirements of RO. Similar to RO, additional pre-treatment, post-treatment, membrane cleaning requirements, and concentrate management could add additional capital and operating cost. The operating cost for the NF system is highly dependent on the site-specific energy cost and on the NF feed quality (MEND, 2014).

2.6.2 Cost-Effectiveness Comparison

2.6.2.1 Nitrate

Technologies deemed feasible for nitrate treatment include MBBR, FBR, ion exchange, and RO. Each technology has been assigned relative cost-effectiveness rankings from 1 to 4, based on capital and operating cost estimates. Cost-effectiveness rankings for nitrate treatment options are presented in Table 2-11 below, with 1 representing the most cost-effective technology and 4 representing the least cost-effective technology.

Table 2-11:
Cost-effectiveness rankings for nitrate treatment options

Treatment Technology	Relative Cost-Effectiveness Ranking – Capital Cost	Relative Cost-Effectiveness Ranking – Operating Cost
Ion Exchange	1	2
MBBR	2	1
FBR	3	4
RO	4	3

On a capital cost basis, ion exchange is the most cost-effective and RO is the least cost-effective, based on estimated equipment and total installed costs. On an annual operating cost (per m^3) basis, MBBR is the most cost-effective and FBR is the least cost-effective.

Further, high feed nitrate concentration increases operating and capital costs and residuals production for FBR systems (MEND, 2014). FRB technology is not considered economically viable for high flow rates (J. Dallaire, personal communication, November 29, 2022).

2.6.2.2 Total Selenium and Dissolved Copper

Technologies deemed feasible for T-Se and D-Cu treatment include RO and NF. Each technology has been assigned relative cost-effectiveness rankings from 1 to 2, based on capital and operating cost estimates. Cost-effectiveness rankings for T-Se and D-Cu treatment options are presented in Table 2-12 below, with 1 representing the most cost-effective technology and 2 representing the least cost-effective technology.

Table 2-12:
Cost-effectiveness rankings for T-Se and D-Cu treatment options

Treatment Technology	Relative Cost-Effectiveness Ranking – Capital Cost	Relative Cost-Effectiveness Ranking – Operating Cost
NF	1	1
RO	1	2

Due to their similarities, RO and NF are equally cost-effective for the treatment of T-Se and D-Cu in terms of equipment and total installed cost; however, NF is more cost-effective than RO from an operating cost standpoint, due to lower energy demands.

2.6.2.3 Total Arsenic

Technologies deemed feasible for T-As are hydroxide precipitation/co-precipitation with coagulants, ion exchange, RO, and NF. Each technology has been assigned relative cost-effectiveness rankings from 1 to 4, based on capital and operating cost estimates. Cost-effectiveness rankings for T-As treatment options are presented in Table 2-13 below, with 1 representing the most cost-effective technology and 4 representing the least cost-effective technology.

Table 2-13:
Cost-effectiveness rankings for T-As treatment options

Treatment Technology	Relative Cost-Effectiveness Ranking – Capital Cost	Relative Cost-Effectiveness Ranking – Operating Cost
Hydroxide Precipitation/Co-Precipitation with Coagulants	1	4
Ion Exchange	2	2
NF	3	1
RO	3	3

On a capital cost basis, hydroxide precipitation/co-precipitation with coagulants is the most cost-effective, and RO and NF are the least cost-effective based on estimated equipment and total installed costs. On an annual operating cost (per m^3) basis, NF is the most cost-effective and hydroxide precipitation/co-precipitation with coagulants is the least cost-effective.

2.7 Selection of Best Achievable Technology

The final step of the BAT assessment is to select the best achievable technology. A best achievable technology is a technology that has been evaluated for feasibility, reliability, control-effectiveness, and cost-effectiveness, and is demonstrated to be best-suited to meet waste discharge standards for the protection of the environment and human health.

Seven treatment technologies were carried forward as candidates for BAT given their ability to achieve applicable discharge limits (nitrate and T-As) or BC WQGs (T-Se and D-Cu) at the final discharge location of Brucejack Mine. The reliability and control-effectiveness evaluations concluded that RO is the most reliable and control-effective technology for all POCs. Alternative technologies that can treat T-As in a reliable and controlled manner include ion exchange, hydroxide precipitation/co-precipitation, and NF. Ion exchange is also deemed reliable and control-effective for nitrate treatment. Of the seven treatment technologies deemed feasible by this BAT assessment, RO is the only option that can reliably meet the target concentrations for T-Se and D-Cu. Therefore, RO is selected as the BAT for effective removal of all POCs in water discharged from the WRTSF during the operations phase.

3. Conclusions

Treatment options for POCs during operations (nitrate, T-Se, D-Cu and T-As) in Brucejack Mine's WRTSF discharge under an increased production scenario were identified and evaluated for feasibility, reliability, control-effectiveness, and cost-effectiveness. Seven technologies were identified for treatment of nitrate, with four deemed feasible and carried forward for further assessment. Six technologies were identified for treatment of T-Se, T-As, and D-Cu, with 2 being deemed feasible for T-Se and D-Cu, and 4 deemed feasible for T-As. The reliability and control-effectiveness evaluations concluded that RO is the most reliable and control-effective technology for all POCs, along with ion exchange (nitrate, T-As), hydroxide precipitation/co-precipitation with coagulants (T-As), and NF (T-As). The most cost-effective technologies in terms of capital and operating cost, respectively, are ion exchange and MBBR for nitrate treatment, RO and NF for T-Se and D-Cu treatment, and hydroxide precipitation/co-precipitation with coagulants and NF for T-As treatment.

Based on the evaluations of feasibility, reliability, and control-effectiveness described in this BAT assessment, the stringent treatment objectives for T-Se and D-Cu require the use of RO technology. The only alternative technology deemed feasible for treatment of these two POCs to the treatment objectives is NF; however, it is less suitable due to its larger pore size and lower removal efficiency. Although alternative treatment options are also well-suited for nitrate (*e.g.*, ion exchange) and T-As (*e.g.*, hydroxide precipitation/co-precipitation with coagulants), RO offers a robust treatment solution for these parameters as well. Therefore, RO is considered best achievable technology to meet the treatment objectives for all POCs, based on the flows and water quality predicted for WRTSF discharge during operations under the increased production scenario.

An RO-based system will require upstream removal of TSS via metal precipitation, clarification, and filtration processes. An RO process will also require management/treatment of the concentrated waste stream, which will add significant operational complexity. Based on the outcome of this BAT assessment, engagement has been initiated with treatment vendors to obtain site-specific proposals and cost estimates for an RO-based system to treat the outflow of the WRTSF at Brucejack Mine. Based on this vendor feedback, the capital cost for a prefabricated RO-based system is expected to be approximately $73,000,000 CAD, assuming a design flow rate of 5,760 m^3/hr. This design flow rate exceeds the average flow predicted to report to BJ 3.10 during operations (1,878 m^3/hr; Lorax, 2023a) by a factor of 3 to accommodate treatment during high-flow periods. The annual operating cost for the system is expected to be approximately

$27,500,000 CAD per year. This system is expected to produce approximately 320 m^3/hr of sludge (with 0.5-1% dryness) and 1,650 m^3/hr of RO concentrate with a conductivity of 2,930 µS/cm. The aforementioned cost estimates of the RO-based system do not include costs associated with downstream treatment or handling of these residual waste products.

Appendix 5-5: Derivation of Current Discharge Limits in Effluent Permit PE-107835

Appendix 5-5-1: Derivation of Discharge Limits for Iron and Silver

1 SCIENCE BASED ENVIRONMENTAL BENCHMARKS

1.1 SUMMARY OF APPROACH

BC water quality guidelines for the protection of freshwater aquatic life (BC FWAL) are derived to be protective of the most sensitive species and life stages of aquatic life present in British Columbia. These are generic guidelines that may not account for local conditions that could make BC FWAL guidelines over- or under-protective for a particular waterbody. The most common conditions for which generic guidelines are over-protective are for 1) waterbodies in which sensitive species are absent and do not have the potential to occur there, 2) waterbodies with site-specific chemistry that reduces the toxicity of a contaminant, and 3) waterbodies with naturally elevated levels of a contaminant. Under these circumstances, it is warranted to derive science based environmental benchmarks (SBEBs) which are protective of the local aquatic life.

SBEBs developed for the Brucejack Creek receiving environment station BJ 2.62 are presented below for parameters that are predicted to exceed generic BC FWAL guidelines. Separate SBEBs are developed for high flow and low flow months for parameters that have background concentrations that seasonally exceed BC FWAL guidelines when higher flows in Brucejack Creek carry higher suspended sediment loads. Overall, the SBEBs are derived to define a contaminant level below which no significant effect will occur to aquatic life in Brucejack Creek.

1.2 PROPOSED SCIENCE BASED ENVIRONMENTAL BENCHMARKS

SBEBs have been derived for four parameters (nitrite, iron, silver, and zinc) in support of the MA/EMA permit application (Table 1.2-1). SBEBs for Fe and Ag (Section 1.2.1) are based on background concentrations of these parameters, which vary seasonally, therefore different SBEBs are proposed for low flow (October to April) and high flow (May to September) months.

Table 1.2-1. Proposed Science Based Environmental Benchmarks for Station BJ 2.62 in Brucejack Creek

			Proposed SBEB	
Parameter	Units	BC FWAL[1]	Low flow	High flow
Nitrite[2]	mg-N/L	0.02	0.18	0.18
Iron-total	mg/L	1.0	1.0	1.70
Silver-total	mg/L	0.000050	0.000120	0.000460
Zinc-total[3]	mg/L	0.0075	0.055	0.055

Notes:
[1]BC long-term water quality guideline for the protection of freshwater aquatic life.
[2] ZiNitrite guideline assumes that chloride is <2 mg/L.
[3]Zinc guideline and SBEB are hardness dependent. The guideline shown is for background hardness of 28 mg/L as $CaCO_3$. For other hardness levels the formula SBEB (mg/L)=EXP(0.72(LN(hardness))-2.8) applies.*

The proposed SBEBs for nitrite (Section 1.2.2) and zinc (Section 1.2.3) were derived using the recalculation procedure described in BC MOE (2013a). Nitrite and zinc BC FWAL guidelines were derived to be protective of fish, which are the most sensitive taxon to these parameters. Brucejack Creek is not fish bearing, and the closest fish bearing stream is approximately 20 km downstream of Brucejack Creek, therefore the recalculation procedure was used to derive a benchmark that is protective of aquatic life in Brucejack Creek.

1.2.1 Rationale for Iron and Silver SBEBs

The background concentration procedure (BC MOE 2013a) is applicable to waterbodies with natural background levels of a parameter that are higher than the generic BC FWAL guideline. This approach is relevant to Brucejack Creek, which has elevated levels of some metals during high flows, presumably due to metals associated with suspended sediments.

SBEBs were derived by determining the 95th percentiles of BJ 2.62 baseline water quality concentrations for both low flow months (October-March) and high flow months (May-September). If calculated values exceeded the corresponding generic BC FWAL guidelines, the baseline 95th percentile was adopted as the SBEB. Only 2009 to 2013 data from the ERM Rescan-curated baseline water quality dataset were used in the calculation of SBEBs (ERM Rescan, 2014c). As such, samples identified by ERM Rescan as potentially mine-impacted were not included in the derivation of 95th percentile SBEBs. Samples collected during earlier monitoring programs (1987-2001) were also excluded from the calculation of 95th percentiles, as these samples were not analyzed for silver or analyses used high analytical method detection limits. The 2009 to 2013 monitoring period includes data from samples analyzed for an analytical suite of 33 total and dissolved analytes (with anions and nutrients), and low method detection limits.

Baseline concentrations of silver are greater than BC FWAL guideline during both low flow and high flow months (Table 1.2-2). Based on the background concentration procedure, SBEBs are proposed for total silver (0.00012 mg/L during low flow months, 0.00046 during high flow months).

Table 1.2-2. Comparison of Maximum Modeled Concentrations during Construction and Operations Phases to Baseline 95th Percentiles for Total Iron and Silver.

			Low Flow Months (Oct – Apr)[2]		High Flow Months (May – Sep)[3]	
Parameter	Units	BC FWAL[1]	Maximum modeled BJ 2.62	BJ 2.62 Baseline 95th Percentile	Maximum modeled BJ 2.62	BJ 2.62 Baseline 95th Percentile
Iron-T	mg/L	1.0	0.588	0.324	0.924	**1.70**
Silver-T	mg/L	0.000050	**0.000057**	**0.000120**	**0.000110**	**0.000460**

Notes:
[1]BC water quality guideline for the protection of freshwater aquatic life (FWAL). Guidelines shown are for 30-day concentration Hardness-dependent guidelines based on median baseline hardness at BJ 2.62 (28 mg/L as $CaCO_3$).
[2]Data range June 2011 to August 2013; n = 16 sample events
[3]Data range October 2011 to April 2013; n = 11 sample events
Concentrations that exceed guidelines are shown in bold font; values shaded grey are proposed SBEBs.

Baseline concentrations of iron are greater than BC FWAL guideline during high flow months but not low flow months, therefore an SBEB for total iron is proposed only for high flow months (1.7 mg/L).

1.2.2 Rationale for Nitrite SBEB

The current BC 30-day FWAL guideline is based on three studies (Russo and Thurson 1977; BC Research 1981; Sigma 1983) that indicated that fish are the most sensitive taxon to nitrite toxicity. The BC FWAL long-term guideline of 0.02 mg-N/L was based on the conclusion that 0.02 mg/L NO_2-N is the maximum level acceptable for salmonids for continuous exposure in fish rearing tanks (Nordin and Pommen 1986). Toxicity testing indicated that nitrite toxicity is reduced by chloride, therefore BC FWAL guidelines for nitrite are chloride-dependent.

Within the context of the aquatic species assemblage in Brucejack Creek, invertebrates represent the most sensitive taxon present. Fish are absent from Brucejack Creek. Additionally, there are few toxicity data on nitrite effects to algae and macrophytes, although potential environmental effects more likely relate to issues associated with eutrophication from nitrite as a nutrient source (Nordin and Pommen 1986). Therefore, an SBEB is proposed based on the sensitivity of invertebrates to nitrite toxicity.

The BC WQG for nitrite (Nordin and Pommen 1986) describes only two invertebrate studies available at the time of guideline derivation: 1) Wickens (1976), in which a 3-4 week nitrite LC_{50} of 15.4 mg-N/L was reported for *Macrobrachium rosenbergii* (a tropical freshwater prawn); and 2) Beitinger and Huey (1981), in which a 96-hour LC_{50} of 1.9 mg-N/L for *Procambrus simulans* (a crayfish) is reported. Based on the limited dataset, consideration of more recent toxicity studies is warranted for the development of an SBEB for Brucejack Creek.

US EPA (2010) recently led a series of tests that add considerably to the invertebrate nitrite toxicity dataset (Table 1.2-3). The only chronic toxicity test conducted was a 7-day reproduction test using the waterflea *Ceriodaphnia dubia.* The Lowest Observable Effects Concentration from that test was 1.8 mg/L. This formed the basis for an SBEB derived in the Brucejack Exploration Phase Technical Assessment Report. The SBEB was 0.18 mg/L, derived by multiplying the LOEC by an uncertainty factor of 0.1. This same concentration is proposed as an SBEB for Construction, Operation, and Closure phases.

Included in Table 1.2-3 are data from site-specific toxicity tests recently conducted using water collected from the underground drill water sump tested with *Daphnia magna* and water collected from site BJ 2.62 tested with *Chironomus dilutus* (Table 1.2-4). These tests were conducted by spiking site water with nitrite, nitrate, and ammonia at proportions recently measured in effluent from the Exploration water treatment plant, in order to simulate effluent. *Chironomus dilutus* is a midge, and is representative of invertebrates that occur in Brucejack Creek. No toxicity to *C. dilutus* occurred at any of the concentrations tested, up to 2 mg/L. These data support the SBEB of 0.18 as being protective of aquatic life in Brucejack Creek.

The lowest endpoint in the invertebrate nitrite toxicity dataset (Table 1.2-3) is 1.0 mg/L for the stonefly *Amphinemura delosa*. The proposed SBEB of 0.18 mg/L is equivalent to an uncertainty factor of 0.18 applied to the *A. delosa* endpoint. Given that 13 endpoints from 9 invertebrate species were reviewed, the application of an uncertainty factor of 0.18 provides confidence that aquatic life in Brucejack Creek will be protected at the SBEB. Further confidence that the proposed SBEB is protective of aquatic life in Brucejack Creek is provided by the site specific data (Table 1.2-4).

Table 1.2-3. Estimates of Nitrite Toxicity to Freshwater Invertebrates

Test Species	Endpoint [2]	Concentration (mg NO_2-N/L)	Source
Forestfly, Amphinemura delosa	96-hour LC_{50}	1.0	US EPA 2010
Water flea, Daphnia magna	48-hour LC_{50}	1.45	Pretivm[1] (see Table 1.2-3)
Amphipod crustacean, Hyalella azteca	96-hour LC_{50}	1.5	US EPA 2010
Water flea, Ceriodaphnia dubia	7-day LOEC reproduction	1.8	US EPA 2010
Crayfish, Procambarus simulans	96-hour LC_{50}	1.9	Beitinger and Huey (1981), in Nordin and Pommen (1986)
Water flea, Ceriodaphnia dubia	48-hour LC_{50}	4.6	US EPA 2010
Water flea, Ceriodaphnia dubia	7-day LC_{50}	4.7	US EPA 2010
Water flea, Ceriodaphnia dubia	48-hour LC_{50}	5.1	US EPA 2010
Freshwater prawn, Macrobrachium rosenbergii	3-4 week LC_{50}	15.4	Wickens (1976), in Nordin and Pommen (1986)
Midge, Chironomus dilutus	48-hour LC_{50}	15.6	US EPA 2010
Fingernail clam, Sphaerium simile	96-hour LC_{50}	55.7	US EPA 2010
Fatmucket clam, Lampsilis siliquoidea	96-hour LC_{50}	177	US EPA 2010
Midge, Chironomus dilutus	96-hour LC_{50}	>2	Pretivm[1] (see Table 1.2-3)

Notes:
[1] Toxicity testing recently commissioned by Pretivm, conducted at Maxxam Analytics (Burnaby, BC). Tests used site water spiked with nitrogen species (NO_3, NO_2, and NH_4,) at proportions recently measured in effluent from the MWTP (19% NH_4, 77% NO_3, and 4% NO_2).
[2] LC_{50}: Concentration required to cause mortality to 50% of test organisms. ; EC_{50}: Concentration required to cause effect in 50% of test organisms; LOEC: Lowest Observed Effect Concentration.

Table 1.2-4. Results of Site-specific Toxicity Testing of Nitrogen

Nitrogen Concentration Added			Percent Survival		Cell Yield
Nitrite-N (mg/L)	Nitrate-N (mg/L)	Ammonia-N (mg/L)	*Daphnia magna* (waterflea)	*Chironomus dilutus* (midge)	*Pseudokirchneriella subcapitata* (alga)
<0.0050	<0.020	0.0434	100%	100%	122 cells
0.147	2.68	0.722	100%	100%	136 cells
0.265	5.32	1.36	100%	100%	154 cells
0.510	10.8	2.38	100%	100%	147 cells
1.03	21.5	5.35	90%	100%	139 cells
2.05	44.3	11.1	15%	100%	129 cells
LC/EC_{50} for nitrite			**1.45 mg/L**	**>2 mg/L**	**>2 mg/L**

1.2.3 Rationale for Zinc SBEB

A zinc SBEB was developed by ERM Rescan under separate cover (Appendix 1).

Attention: Mr. Mark Love, Authorizations Section Head – Mining Team Mr. Rusto Martinka, Sr. Environmental Protection Officer

Dear Mr. Love and Mr. Martinka;

Re: PE-107835 Brucejack Gold Mine – Effluent Permit Amendment Application #4

This letter is an application to amend several conditions of Effluent Permit 107835 (PE-107835), issued to Pretium Resources Inc. (Pretivm) for the Brucejack Gold Mine. Pretivm is requesting changes to discharge limits for nitrogen species; several water quality monitoring requirements; permitted discharge locations for effluents discharged to Brucejack Lake; and removal or rewording of the permit condition pertaining to Mine Water Treatment Plant (WTP) sludge disposal.

Water quality monitoring of Brucejack Lake has lead to an improved understanding of nitrogen loading to the lake and secondary processes that affect the concentration of ammonia, nitrite and nitrate in Brucejack Lake. The water quality model has been updated for ammonia, nitrite and nitrate, and an effects assessment has been completed for revised model predictions. Amendments are requested for compliance requirements relating to nitrogen compounds in the WTP effluent and at BJ 3.10.

The amendment requests are listed in the order they appear in PE-107835.

1. **Condition 1.1.1 – Cumulative Compliance Requirements**

Condition 1.1.1 includes the following condition regarding nitrite and nitrate:

The characteristics of the Brucejack Lake Outlet (BJ 3.10) must be equivalent to or better than:

Parameter	Maximum	Units
Nitrite	75	µg/L as N
Nitrate	3	mg/L as N

Amendment request: Amend the maximum limits for nitrate and nitrite specified in Condition 1.1.1 to those listed below:

The characteristics of the Brucejack Lake Outlet (BJ3.10) must be equivalent to or better than:

Parameter	Maximum	Units
Nitrite	0.24	mg/L as N
Nitrate	11.5	mg/L as N

Rationale: Updated water quality modeling indicates that nitrate and nitrite are predicted to exceed the current discharge limits and may reach concentrations of 11.5 mg/L NO_3-N and 0.24 mg/L NO_2-N. An ecological effects assessment has concluded that the potential for adverse effects to aquatic communities in the receiving environment due to the updated modeled concentrations of nitrate and nitrite is not significant. Therefore, these concentrations are recommended as maximum limits for the BJ 3.10 monitoring station. Supporting information is provided in Attachment A.

2. Condition 1.2.2 – Water Treatment Plant Effluent

Condition 1.2.2 includes the following condition regarding nitrite:

The characteristics of the Water Treatment Plants (WTP) discharge should not exceed the following concentrations after treatment. If these levels are exceeded, notification is required following the procedures as per Sections 5.4 and 5.5.

Parameter	Construction WTP Maximum	Operation WTP Maximum	Units
Nitrite	1.9 (max) 0.65 annual average	1.9 (max) 0.65 annual average	mg/L as N

Amendment request: It is requested that nitrite be removed from Condition 1.2.2.

Rationale: Nitrite concentration in the WTP effluent does not influence the nitrite concentration at the Brucejack Lake outlet (BJ 3.10). Nitrite concentration at the lake outlet is controlled by processes occurring in the lake. The most important process is nitrification, which converts a large proportion of ammonia and nitrite loadings to the lake to nitrate. Supporting information is provided in Attachment A.

3. **Condition 1.2.4: Location of WTP effluent pipeline**

Condition 1.2.4 states:

> *1.2.4 The location of the treatment plant and the deep lake outfall are as shown on Site Plan B and D. The sources of WTP influent are mine water and the contact water pond(s).*

Amendment request: Please replace the reference to Site Plans B and D to Site Plans A and B. Please update both Site Plans to show the correct position of the Operations WTP effluent pipeline, as well as the locations of the direct discharge lines from the Contact Water Pond to Brucejack Lake.

Rationale: The Operations WTP pipeline will be routed adjacent to the tailings pipeline for most of its length (i.e. similar to the originally permitted routing and outfall), but will discharge below 30 m depth, nearer to shore than the tailings outfall. The positioning and outfall are designed to prevent scouring of tailings deposited on the lake bottom. An updated Operations site plan is included in Attachment B.

4. **Condition 1.5.3 – Treated Domestic Wastewater**

Condition 1.5.3 states:

> *The Permittee must provide the various plans required under the Municipal Wastewater Regulation as well as the formal as built plans for the sewage treatment plant, all of which shall be signed off by a Qualified Professional prior to commencing the discharge of treated domestic effluent.*

Amendment request: It is requested this condition be removed from the Permit.

Rationale*:* Pretivm considers that this condition has been satisfied and should therefore be removed from the Permit. The sewage treatment plant system is comprised of 3 separate pre-packaged units that use the same treatment process: two Filterboxx C-75 units and one C-25 unit. The STP is not constructed on site and thus the as-built design clause is not applicable to the Brucejack STP system, since the units are delivered to site as 'ready to go' units. The design plans for the first C-75 unit were included in the Mines Act/Environmental Management Act Permit Application. The first C-75 unit was registered under the Municipal Wastewater Regulation in June of 2014 when the first system came online. The second C-75 unit is identical to the first and the additional C-25 unit employs the same treatment process, but treats a lower volume of waste. The application for the C-25 unit, submitted to BC MOE October 15, 2015, contains additional information specific to that treatment unit.

5. **Condition 3.2 – Source Control of Nitrite and Nitrogen**

Condition 3.2 states:

> *The Permittee must implement the Nitrogen Source Control Program (NSCP) as documented in Appendix 6-T of the May 2015 application for a permit. The NSCP indicates that the rate of the explosive usage within the mine will be managed using nitrite, nitrate and or ammonia monitoring at the Water Treatment Plant(s) and supplemental "in Mine" monitoring as necessary to ensure the cumulative Nitrite Limit in Section 1.1 is met.*
>
> *The Permittee must maintain graphical records of the Nitrite Management and monitoring similar to figure 5.1-1 of Appendix 6-T for inspection at the request of Environmental Protection Staff and submission with the annual reports.*

Amendment request: It is requested that Condition 3.2 be amended to the following:

> *The Permittee must implement the current version of the Nitrogen Management Plan (NMP). The NMP describes source control measures, monitoring, auditing and reporting activities that are undertaken to ensure nitrogen sources are controlled and minimized and that the cumulative Ammonia, Nitrite and Nitrate Limits in Section 1.1 are met.*
>
> *The Permittee must maintain records of the activities described in the NMP available for inspection at the request of Environmental Protection Staff.*

Rationale: NMP monitoring and mitigation procedures have been updated and are described in the NMP document. These procedures will continue to evolve as the Project progresses. It is requested that the Permit condition make a generic reference to the current version of the NMP. Specific monitoring, recordkeeping and reporting requirements are described in the NMP. A copy of the updated NMP is included as Appendix A of Attachment A.

6. **Condition 3.7 – Mine Water Treatment Plant Sludge**

Condition 3.7 states:

> *The Sludge(s) from the Construction and/or Operation Mine Water Treatment plants must be characterized using appropriate methods within 90 days of commissioning each plant and remain in storage on site until it is determined that:*
>
> *It is not Hazardous Waste under the Hazardous Waste Regulation, and, the proposed disposal option is approved by the Director.*
>
> *Storage of Water Treatment Plant sludge onsite must not exceed twelve (12) months, unless approved by the Director. Sludge storage must be done in a manner acceptable*

to the Director.

Amendment request: It is requested that Condition 3.7 be amended to the following:

Disposal of sludge from the Operations Mine Water Treatment plant does not require MOE approval if it is disposed off-site at a licensed facility.

On-site co-disposal of WTP sludge with waste rock or tailings to Brucejack Lake is permitted following prior approval by the Director and provided the long-term stability and influence on water quality is assessed and meets the requirements of the ML/ARD management plan.

Storage of Water Treatment Plant sludge onsite must not exceed twelve (12) months, unless approved by the Director. Sludge storage must be done in a manner acceptable to the Director.

Rationale: Off-site sludge disposal at a facility licensed to receive this type of waste has been on-going since the initial characterization of Construction WTP sludge was completed. BC MOE already regulates the licensed haulers/disposers of Brucejack Mine WTP sludge and BC and Alberta (applicable jurisdiction dependent on which facility the sludge is disposed at) regulate the facilities themselves. With respect to co-disposal of sludge with tailings and/or waste rock, long-term stability studies for WTP sludge are ongoing and a lake disposal option is being evaluated in accordance with the ML/ARD management plan.

7. Appendix B – Surface Water Quality Monitoring Requirements at BJ3.10 and BJ2.62

Appendix B states:

Appendix B – Surface Water Quality Monitoring Requirements

Sample Site Name	Metals & General	5 in 30 days
Weir at BJ 3.10	Weekly	Freshet & Fall
BJ 2.62	Monthly	Freshet & Fall

Amendment request: It is requested that 5 in 30 day water quality sampling be removed from Appendix B for sites BJ 3.10 and BJ 2.62.
Rationale: Water quality is monitored weekly year-round at BJ 3.10, therefore specifying 5 in 30 monitoring at BJ 3.10 is not necessary. Site BJ 2.62 is a legacy monitoring location from when WTP and STP effluents were discharged to Brucejack

Creek. Now that all discharges are to Brucejack Lake, the high frequency sampling done at the lake outlet (BJ3.10) is adequate to characterize any mine-related changes to water quality. The high frequency, 5 in 30 sampling at BJ2.62 does not provide any additional meaningful information.

8. **Appendix B – Surface Water Quality and Flow Monitoring Requirements at BJ2.62**

For monitoring station BJ 2.62 Appendix B states:

Appendix B – Surface Water Quality Monitoring Requirements

Sample Site Name	Flow Rate / Staff Gauge	5 in 30 days
BJ 2.62	Continuous flow with manual checks 2x/winter 4x/Summer @ low flow and no recent precipitation.	Freshet & Fall

Amendment request: It is requested flow monitoring requirements at BJ2.62 be removed from Appendix B.

Rationale: BJ 2.62 is a legacy compliance station for the time period when the WTP and STP were discharging to Brucejack Creek. Field observations over the past few years indicate the streambed at BJ 2.62 is not suitable for accurate continuous flow measurements. Flow measurements requirements in Appendix B at stations BJ3.10 and BJL-H1a are sufficient to characterize flows in Brucejack Creek.

9. **Appendix B – Surface Water Quality and Flow Monitoring – CWP**

Appendix B states:

Appendix B – Surface Water Quality Monitoring Requirements

Sample Site Name	Metals and General
CWP influent at WTP	2x/month
CWP direct discharge to lake	1x for each direct discharge otherwise 1x/month during sQtr 2 & 3

Amendment request: It is requested that Appendix B be amended as follows:

Appendix B – Surface Water Quality Monitoring Requirements

Sample Site Name	Metals and General
CWP influent at WTP	2x/month (when discharging to WTP)
CWP direct discharge to lake	1x for each direct discharge

Rationale: Under normal circumstances the CWP collects surface runoff during the snow-free months and discharge from the CWP is directed to the WTP. The CWP water quality is measured as "CWP influent at WTP" twice a month. Water quality monitoring at the CWP is redundant when the monitoring is also conducted at the WTP influent location. As well, water quality sampling at the CWP is often unsafe during sQtr 2 (April through June) due to snow and ice on the pond surface and embankments.

Please contact me by email or at (250) 877-9011 to discuss this Permit amendment request or if you require any additional information.

Sincerely,

Sylvia Van Zalingen

Executive Summary

PRETIVM

Executive Summary

This report provides updated nitrogen species (ammonia, nitrite and nitrate) predictions and assessment for the Brucejack Gold Mine effluent discharge from Brucejack Lake at site BJ 3.10 using additional water quality data collected and compiled subsequent to the initial Effluent Permit PE-107835 application. This report has been specifically compiled in support of an application by Pretium Resources Inc. (Pretivm) to amend Brucejack Gold Mine Effluent Permit PE-107835 to:

1) increase discharge limits at the lake outlet (site BJ 3.10) for nitrate (from 3.0 mg-N/L to 11.5 mg-N/L) and nitrite (from 0.075 mg-N/L to 0.24 mg-N/L); and
2) remove the Mine Water Treatment Plant (WTP) effluent discharge limit for nitrite.

In support of these proposed amendments, the monitoring data collected during the Project's Exploration and Construction phases have been used to: 1) refine mine-related nitrogen source terms; 2) quantify the extent to which nitrification processes are occurring within Brucejack Lake; 3) generate revised water quality predictions for receiving environments downstream of Brucejack Lake (Brucejack Creek and Sulphurets Creek); and 4) evaluate the potential for adverse effects to aquatic life downstream of Brucejack Lake.

The primary source of nitrogen compounds to Brucejack Lake is residue from explosives use; contributions from treated domestic wastewater and background inflows are negligible. Explosives-related nitrogen compounds are currently introduced to Brucejack Lake from WTP effluent and blasted waste rock deposition. Once the mill is operational, the tailings slurry discharge will also be a source of nitrogen loadings to Brucejack Lake. The Nitrogen Management Plan (NMP) outlines source control measures that have been implemented to limit nitrogen loading to Brucejack Lake.

Current PE-107835 discharge limits for nitrogen compounds were developed based on previous water quality predictions from Environmental Assessment and initial permitting that assumed conservative behaviour of nitrogen compounds in Brucejack Lake (*i.e.* no secondary reactions). The assumption that there is no attenuation of nitrite in the lake necessitated that a nitrite discharge limit be set for effluent from the WTP.

Pretivm has implemented nitrite treatment of WTP effluent in order to meet discharge limits. Monitoring data from the Construction phase of the Project demonstrate that nitrogen in the lake has been behaving non-conservatively, with ammonia and nitrite being converted to nitrate, likely by microbial nitrification processes. Based on the observation that nitrite conversion to nitrate is occurring naturally in the lake, and noting that the

dominant source of nitrogen is from waste rock deposition (a source that cannot be treated), it is recommended that the requirement for a WTP effluent discharge limit for nitrite be removed from the Effluent permit.

Water quality predictions for nitrogen compounds have been updated considering the updated source terms and nitrification processes occurring within Brucejack Lake. Revised predictions for BJ 3.10 indicate the potential for concentrations of nitrate (up to 11.5 mg-N/L) and nitrite (up to 0.24 mg-N/L) that are above the current discharge limit at BJ 3.10. The maximum predicted ammonia concentration of 0.49 mg-N/L is below the current discharge limit.

Based on the results presented here, it is recommended that Effluent Permit PE-107835 be amended to reflect the current understanding of nitrogen species in the lake. Specifically, the magnitude of nitrite attenuation in Brucejack Lake demonstrates that treatment measures implemented to control nitrite concentrations in the WTP discharge are not necessary, and therefore it is recommended that the WTP effluent discharge limit for nitrite be removed. Although the updated water quality model predicts higher concentrations of nitrate and nitrite at the lake outlet, an updated effects assessment carried out for the receiving environment concludes that potential effects to aquatic life in the receiving environment will be not significant at the predicted concentrations of nitrate and nitrite. Based on the updated effects assessment, it is recommended that the BJ 3.10 discharge limits for nitrate and nitrite be amended to 11.5 mg/L-N/L and 0.24 mg-N/L, respectively.

1. Introduction

1. Introduction

1.1 Overview and Objectives

This report provides updated nitrogen species (ammonia, nitrite and nitrate) predictions and assessment for the Brucejack Gold Mine effluent discharge from Brucejack Lake at site BJ 3.10 using additional water quality data collected and compiled subsequent to the initial Effluent Permit PE-107835 application. This report has been specifically compiled in support of an application by Pretium Resources Inc. (Pretivm) to amend Brucejack Gold Mine Effluent Permit PE-107835 to:

1) increase discharge limits at the lake outlet (site BJ 3.10) for nitrate (from 3.0 mg-N/L to 11.5 mg-N/L) and nitrite (from 0.075 mg-N/L to 0.24 mg-N/L); and
2) remove the Mine Water Treatment Plant (WTP) effluent discharge limit for nitrite.

Specific objectives of this report in support of the proposed discharge limits changes include the following:

- Quantify inorganic nitrogen loadings to Brucejack Lake;
- Describe nitrification processes (ammonia and nitrite oxidation) occuring in the lake based on empirical evidence from water quality monitoring;
- Generate revised water quality predictions for inorganic nitrogen species at the lake outlet;
- Evaluate the potential for adverse effects to aquatic life in the receiving environment; and
- Provide recommendations with respect to nitrogen discharge limits at the WTP and lake outlet.

1.2 Background to Nitrogen Species Loads to Brucejack Lake

The Brucejack Gold Mine is currently in the advanced stages of Construction, with Operations planned to begin in 2017. Relevant to nitrogen species loadings to Brucejack Lake, waste rock (source of nitrogen species from explosives residues) was first deposited subaqueously in Brucejack Lake in 1999 in response to BC Ministry of Energy and Mines direction to a previous site owner – Newhawk Resources – to prevent ML/ARD from waste rock excavated by Newhawk during advanced underground exploration conducted in the 1980's. Advanced underground exploration was re-initiated by Pretivm in early 2013, with subaqueous waste rock deposition occurring intermittently (dependent on development) thereafter until September 2015, when mine Construction was initiated. Large-scale

surface excavation of waste rock occurred during late 2015 and through much of 2016 for surface infrastructure development. There has also been a gradual ramp-up of underground mine development within this period.

Treatment of underground mine water prior to discharge was initiated in early 2013. Treated effluent discharge was to Brucejack Creek until December 2015, at which time it was redirected to Brucejack Lake. Nitrogen species were not treated until late 2014, at which time treatment to oxidize nitrite to nitrate was introduced. Nitrite treatment has occurred to the present time.

Other potential sources of nitrogen species loads to Brucejack Lake include a non-PAG (NPAG) quarry located at the east end of Brucejack Lake (quarry produces aggregate for construction and road surfacing), and treated domestic wastewater effluent. The domestic wastewater effluent discharge was initially to Brucejack Creek, but was redirected to Brucejack Lake in March 2016.

A Nitrogen Management Plan (NMP) describing source control measures for nitrogen compounds was implemented in December 2014, along with enhanced monitoring for nitrogen compounds at upstream and discharge locations. The NMP is an adaptive management plan that is updated, as necessary, to achieve source control objectives to minimize nitrogen losses from explosives use and was last updated November 2016.

A total of 123,000 m^3 of rock from underground workings and 511,000 m^3 of surface excavation were deposited in Brucejack Lake from December 2014 through August 2016. An additional ~25,000 m^3 of waste rock was excavated during autumn 2016 to expand the Contact Water Pond (CWP) to its design limit. The WTP discharged 743,000 m^3 of effluent during the December through August, 2016 period. The rate of underground excavation increased from approximately 1,400 m^3/week in January 2015 to approximately 9,700 m^3/week in August 2016. Underground excavation will increase to approximately 12,000 m^3/week during the remaining Construction Phase (May 2017), and drop to approximately 8,000 m^3/week during the mine Operations Phase.

1.3 Monitoring Data

Water quality monitoring of Brucejack Lake has been ongoing through the Exploration and Construction phases, and includes lake water column profiling at multiple depths and sampling at the lake outlet (site BJ 3.10). The data indicate nitrogen loads to Brucejack Lake have increased, commensurate with increases in underground and surface rock excavation. The concentrations of nitrate, ammonia and nitrite at the lake outlet have remained below permitted limits. The current discharge limits for the lake outlet are 3.0, 0.075 and 1.0 mg-N/L for nitrate, nitrite and ammonia, respectively.

This report uses monitoring data (2014-2016) for discharges to the lake, the lake water column, and the lake outlet to update the water quality model with respect to nitrogen loadings and the behaviour of nitrogen compounds. The results have relevance to water quality predictions and treatment requirements.

1.4 Report Organization

The following chapters provide a description of the NMP (Chapter 2), updates to the water quality model and predictions for nitrogen species (Chapter 3), and an effects assessment based on the updated nitrogen predictions (Chapter 4). Conclusions and recommendations relevant to nitrogen management are provided in Chapter 5.

2. Nitrogen Management Plan

PRETIVM

2. Nitrogen Management Plan

Both the *Mines Act* (MA) Permit M-243 (amended August 4, 2016) and the *Environmental Management Act* (EMA) Permit PE-107835 (amended July 12, 2016) require implementation of a Nitrogen Management Plan (NMP), with specific reference to the NMP included in Appendix 6-T of the MA/EMA Permits Application. An adaptive management approach has been developed that includes regular monitoring and data review, as well as periodic updates of the NMP to respond to changing conditions or requirements. The current Brucejack Gold Mine NMP, dated November 2016, is included as Appendix A and describes source control as the primary mitigation tool for nitrogen species. Further mitigation is achieved through treatment of mine water to remove nitrite prior to discharge to Brucejack Lake. The influence of natural attenuation processes for ammonia and nitrite has not been previously considered in the decision matrix for nitrogen management.

Nitrogen source control is achieved by implementing Best Practices for explosives use at underground mines. By limiting the loss of explosives at the blast face, inputs of inorganic nitrogen compounds to mine water and lake water are minimized. Monitoring is conducted daily and includes blasting records, as well as WTP flow and water quality records to confirm explosives use and nitrogen losses are in the expected range. Treatment is used, as necessary, to remove nitrite from the WTP effluent. Treatment was conducted with a sodium hypochlorite process from April 2015 through April 2016. A new ozone process was commissioned in August 2016 and is operated as needed to meet nitrite WTP effluent criteria (1.9 mg-N/L max; 0.65 mg-N/L annual average).

The NMP is further supported with regular inspections and blasting practices reviews. Re-blasts are investigated and steps are taken to prevent recurrence. Weekly underground inspections of the water management system and explosives handling practices are planned for implementation in the near future. The overall program is reviewed annually by senior management and action items arising are addressed by follow-up. The NMP is updated as needed based on inputs gained from the adaptive management process.

3. Brucejack Lake Water Quality

PRETIVM

3. Brucejack Lake Water Quality

3.1 Monitoring Program Description

The effects of mine-related discharges on Brucejack Lake water quality have been assessed based on results from a monitoring program first initiated in 2014. The program builds upon baseline data sets and includes lake water column profiling at multiple depths and regular sampling at the lake outlet (station BJ 3.10). Nitrogen loadings to Brucejack Lake have increased due to project development, although concentrations of the various N species have thus far remained well below permitted limits (3.0, 0.075 and 1.0 mg-N/L for nitrate, nitrite and ammonia, respectively).

The following sections describe the major sources of nitrogen to Brucejack Lake, summarize the results of the monitoring programs, quantify the loadings received by the lake, identify nitrification processes occurring in the lake and present the updated water quality predictions for the various nitrogen species. Monitoring data are summarized in Appendix B.

3.2 Nitrogen Sources

3.2.1 Explosives Use and Waste Discharge

Nitrogen losses associated with explosives use represent the major source of nitrogen in Brucejack Lake. The explosives-related nitrogen loadings are carried in mine water and surface contact water discharged via the WTP, as well as residues on blasted rock placed in Brucejack Lake. In contrast, Sewage Treatment Plant (STP) effluent represents a minor source of loadings received by the lake. Background contributions of nitrogen are negligible.

Blasting at Brucejack Gold Mine is conducted using a water resistant ANFO emulsion product (Dyno Nobel TITAN 7000). Underground excavation recommenced in December 2014 with approximately 2,200 kg/week of explosives consumption (corresponding to 800 m^3/week excavation). As the project entered the Construction Phase, mine excavation and explosive consumption increased and currently explosives are consumed at a rate of 35,000 kg/week (corresponding to 9,700 m^3/week excavation). The increase in explosives use is mirrored by an increase in the total nitrogen load in mine water (Figure 3-1). The underground excavation of waste rock and ore will increase to approximately 12,000 m^3/week during the remaining Construction Phase, and drop to approximately 8,000 m^3/week during the mine Operations Phase.

Figure 3-1: Underground explosives use and nitrogen load exported by mine dewatering over the period October 2014 through August 2016.

The underground mine water nitrogen load was compared to the corresponding explosives use to evaluate the nitrogen loading rate to mine water. The 2015 average nitrogen loading rate to mine water was equal to 5.9% of the explosives used (as N). This has improved in 2016 (to the end of August) with the mine water loading rate equal to 4.3% of the explosive used (as N). The higher nitrogen loading rate observed in 2015 reflects the influence of water bearing structures on blast efficiency. Flowing water can prevent efficient explosive consumption leading to non-detonated explosives in the muck pile and mine water, and consequently, increased nitrogen loads in mine water. Significant water bearing structures were encountered in May and September of 2015 leading to difficult blasting conditions. Nitrogen loads in the mine water briefly peaked during both periods (Figure 3-1), dropping after blasting conditions improved and updated blasting practices were implemented.

Underground mine water and Mine Site surface runoff collected in the contact water pond (CWP) are directed to the WTP for treatment prior to discharge, whereas blasted rock is placed directly in Brucejack Lake for subaqueous storage. During placement of waste rock in the lake, soluble nitrogen residues on the rock surfaces (as ammonia, nitrite and nitrate) are released to the lake water column. Quantification of loadings in mine water and lake water indicate that approximately 25% of the explosive residue is derived from mine water, with the balance (approximately 75%) entrained with blasted rock.

WTP and STP effluents are currently discharged continuously to the lake through separate pipelines to depths of 70 m and 30 m, respectively. Total waste loadings (waste rock and

effluents) to Brucejack Lake from various sources between December 2014 and August 2016 are summarized in Table 3-1.

Table 3-1:
Qunatities of waste rock and effluent placed in Brucejack Lake from December 2014 through August 2016

Source	Total Waste Discharged
Underground waste rock to lake	123,000 m^3
Surface waste rock to lake	511,000 m^3
Water treatment plant effluent to lake	743,000 m^3
Sewage treatment plant effluent to lake	5,400 m^3

Explosives use, as well as the excavation and storage of blasted material, are tracked for both surface and underground operations. Surface blasting does not generate a contact water discharge, and therefore explosives losses are not monitored for surface excavation.

For blasting the powder factor (pF) is monitored and represents the amount of explosive required to blast a volume of rock. For underground blasting a pF of 4.0 kg/m^3 was observed in 2015. From January through August 2016 the pF has increased slightly to 4.5 kg/m^3. The surface blasting pF is considerably lower, a full data evaluation was not conducted, however review of individual blast reports indicates the pF was generally in the range of 0.6 to 0.8 kg/m^3.

The waste sources presented in Table 3-1 are described in the following sections in order to quantify the loadings of nitrogen to Brucejack Lake (Section 3.3).

3.2.2 Water Treatment Plant (WTP) Effluent

The WTP is designed to receive and treat underground mine water from mine dewatering and surface contact water collected in the CWP. The WTP removes total suspended sediments (TSS), dissolved metals, and nitrite from influent water. Nitrite treatment is activated only when necessary to meet WTP effluent discharge limits. During active nitrite treatment with sodium hypochlorite from April 2015 through April 2016, nitrite was oxidized to nitrate and ammonia was removed by conversion to nitrogen gas, leaving nitrate as the dominant nitrogen species in the WTP effluent. The ozone process was commissioned in August 2016 to facilitate nitrite oxidization to nitrate, while ammonia is unaffected. Flow and quality of the WTP influents (CWP and underground mine mine) and WTP effluent are described in the sections below.

3.2.2.1 Contact Water Pond (CWP) Flow and Quality

Surface runoff from the core contact water (infrastructure and bedrock excavation) portion of the mine site is directed to the CWP, while the CWP discharge is directed to the WTP. Flow from the CWP commenced in May 2016.

Weekly flows and bi-monthly water quality for the CWP are shown in Figure 3-2. CWP discharges ranged from approximately 800 m^3/week (5 m^3/hr) to 5000 m^3/week (30 m^3/hr) from May through mid-August, originating primarily from surface runoff within the CWP catchment. Total nitrogen concentration ranged between 1 mg-N/L to 5 mg-N/L. CWP water quality and flows during this period were influenced by freshet runoff in June.

Subsequently, between mid-August and late October 2016, dependent on construction needs, WTP effluent and weir dewatering were also periodically directed to the CWP. Construction of the weir at BJ 3.10 commenced mid-August 2016, and construction dewatering was directed to the CWP. The additional flows contributed by WTP effluent water and weir dewatering led to an increase in the CWP flows in the latter half of August, with peak flows of approximately 14,000 m^3/week. The additional inputs to the CWP from the WTP and weir were temporary and flows from the CWP declined when the temporary inputs ceased (data not shown).

Figure 3-2: Contact Water Pond (CWP) discharge and water quality from May 2016 through August 2016; the CWP began operations May 2016.

3.2.2.2 Underground Mine Water Flow and Quality

Mine water quality and dewatering flow are monitored at the influent to the WTP (Figure 3-3). Nitrogen is introduced to mine water through the dissolution of blasting residues at the blast location, through contact with groundwater that enters the mine. In May 2015 and October 2015, excessive losses of non-detonated explosives led to corresponding peaks in nitrogen compounds. Over the period October 2014 through August 2016, the median distributions of inorganic nitrogen compounds (ammonia, nitrate and nitrite) in mine water at the WTP influent were 26.3% ammonia, 66.7% nitrate and 5.3% nitrite, with the balance of 1.7% attributable to measurement uncertainty.

Figure 3-3: Mine dewatering flows and water quality over the period October 2014 through August 2016.

3.2.2.3 Water Treatment Plant Effluent Flow and Quality

WTP effluent water quality and flows are shown in Figure 3-4. Low nitrite and ammonia concentrations were observed during periods of sodium hypochlorite addition (nitrite treatment). When nitrite treatment was inactive, the WTP effluent median distribution of nitrogen species relative to total nitrogen was 26.8% ammonia, 67.6% nitrate and 5.2% nitrite (the balance of 0.4% is attributable to measurement uncertainty), similar to the distribution observed in underground mine water. During periods of active treatment with sodium hypochlorite, the median distribution shifted to 98.9% nitrate, 0.2% ammonia and 0.2% nitrite (with the balance of 0.7% attributable to measurement uncertainty).

Figure 3-4: Water quality and discharge flows for Water Treatment Plant (WTP) effluent over the period October 2014 through July 2016.

3.2.3 Waste Rock

A portion of the blasting residues generated in the underground is stored on rock surfaces and released upon waste rock submergence in Brucejack Lake. Between December 2014 and August 2016, approximately 511,000 m^3 of surface waste rock and 123,000 m^3 of underground waste rock were deposited in Brucejack Lake, thereby releasing soluble nitrogen compounds directly to lake waters.

Surface excavation associated with the earth works program is mostly complete and the bulk of waste rock currently being deposited in Brucejack Lake is from underground mine operations. During the Operations phase, the deposition of underground waste rock will continue at an approximate rate of 115,000 m^3/year in the first year of mining, declining to approximately 20,000 m^3/year in the eleventh year and almost no deposition by year 18. The lake will also receive tailings generated from the process plant at an average rate of 315,000 m^3/year for the duration of mining operations.

Explosives loss rates associated with waste rock deposition were calculated from comparison of water quality data to rock deposition records (Table 3-2). Underground explosives use was calculated from daily records, while surface explosives use was estimated from excavation volumes and assuming a powder factor (pF) of 0.8%. Based on data for 2015, as well as data for January through April 2016, between 12% and 18% of explosives are released to Brucejack Lake through waste rock submergence, while between 3% to 6% of explosives are lost to mine water. Nitrogen loadings from surface waste rock

deposition in the lake were estimated to be 6% of explosives based on a pF of 0.8 and the actual rock volume excavated.

Table 3-2:
Proportional explosive loss rates for 2015 and 2016 (January to April).

Source	2015	2016 (January to April)
Underground explosives loss to mine water	6%	3%
Underground explosives loss to waste	18%	12%
Surface explosives loss to waste	6%	6%

Notes:
The N content in emulsion was assumed to be 29.7% (by mass)
Explosive loss was calculated from explosive use, and the measured N load in the WTP influent and in Brucejack Lake.
Surface blasting explosive quantities calculated assuming a powder factor of 0.8.

3.2.4 Sewage Treatment Plant (STP) Effluent

Treated domestic wastewater from the STP effluent has been discharging to Brucejack Lake since late March 2016 and represents a minor contribution to the overall nitrogen budget of Brucejack Lake. The STP effluent is currently discharged to the lake via a pipeline at 30 m depth. The current rate of discharge is expected to decrease slightly once the Construction phase of the Project is complete and the camp population is reduced to operational levels.

The STP system has three separate treatment units (C25, C75A and C75B) with a combined capacity of 175 m^3/day. Water quality and flow are measured at the discharge of each unit. The monthly loadings for each nitrogen species at each unit were summed to derive monthly estimates (Figure 3-5). The total STP discharge reached approximately 50 m^3/day (1500 m^3/month) in August 2016, well below the permit limit of 175 m^3/day. The combined water quality data show total nitrogen concentrations ranging from 10 to 80 mg/L over the period November 2014 to August 2016, with ammonia and nitrate being the predominant forms of nitrogen.

Figure 3-5: Water quality and discharge flows for Sewage Treatment Plant (STP) effluent for period November 2014 through August 2016; the STP effluent was directed to the lake in April 2016.

3.3 Nitrogen Loadings to Brucejack Lake

Nitrogen loadings to Brucejack Lake occur dominantly through waste rock deposition and to a lesser extent through WTP effluent discharge. The STP-treated domestic effluent relative to other sources is a negligible contribution of nitrogen to the lake. Likewise, baseline water quality monitoring indicates there is no significant contribution of nitrogen from natural inflows.

The largest nitrogen loadings have been associated with underground waste rock (peaking at 5,700 kg-N/month in July 2016) and WTP effluent (peaking at 2,100 kg-N/month in August 2016) (Figure 3-6). Surface blasting nitrogen contributions peaked in January 2016 at 1,800 kg-N/month and declined to 250 kg-N/month in August 2016. The STP discharge contributed a peak nitrogen load of 60 kg-N/month in July 2016.

Figure 3-6: Monthly nitrogen loadings for the period November 2014 through August 2016 for Water Treatment Plant (WTP), Sewage Treatment Plant (STP), underground (UG) rock and surface rock.

Unit quantities for nitrogen residues on waste rock and in WTP effluent were calculated for 2015 and 2016 (January to April) (Table 3-3). For 2015, the underground waste rock residue was estimated to be 0.069 kg-N/t with a lower residual of 0.054 kg-N/t observed in 2016 (January through April). In 2015, there were several incidents of underground blasting through water bearing structures with significant flowing water (May and September) that lead to an increased loss of nitrogen compounds from explosives and ultimately contributed to a higher average nitrogen residual in that year. The lower nitrogen residuals observed to date in 2016 are more representative of current blasting practices. The surface waste rock residual was estimated to be constant at 0.005 kg-N/t during both years. The loading of nitrogen in WTP effluent rose from 0.011 kg-N/m^3 in 2015 to 0.020 kg-N/m^3 in 2016 (January through April). This increase reflects the higher excavation rate and explosives use in 2016 compared to 2015.

Table 3-3:
Nitrogen loading rates for 2015 and 2016 (January to April).

Source	2015	2016 (January to April)
Underground waste loading rate (kg-N/t)	0.069	0.054
Surface waste loading rate (kg-N/t)	0.005	0.005
Water treatment plant effluent loading rate (kg-N/m^3)	0.011	0.020

3.4 Brucejack Lake Water Quality Monitoring Data

All mine-related nitrogen loadings report to Brucejack Lake and water quality monitoring programs have been developed to quantify the loadings received by the lake. The lake has a single outlet and nitrogen export is measured at this location (BJ 3.10). Flows and turbidity are continuously monitored with sensors and water quality samples collected on a weekly basis (as outlined Section 3.4.1). Lake chemistry has also been monitored since 2014 at multiple depths in the water column at a station positioned over the deep (80 m) portion of the lake (station BJ 35). Monitoring at BJ 35 was developed to evaluate nitrogen species conversions, as well as the mixing of nitrogen compounds throughout the water column.

3.4.1 BJ 3.10 Lake Outlet Data

Water quality and flow monitoring data for BJ 3.10 over the period September 2014 to August 2016 were compared to model predictions. Over this period, discharge flows followed seasonal trends with low flows from December through April ranging from approximately 100,000 m^3/month to 200,000 m^3/month (Figure 3-7). From May through October, flows were significantly higher, ranging from 1,500,000 m^3/month to 3,000,000 m^3/month. The observed flows at BJ 3.10 are in agreement with seasonal trends and flows predicted by the MA/EMA water balance model, with flows in 2015 and 2016 (January through August) representing approximately 80% and 75% of the model predictions, respectively.

Figure 3-7: Observed monthly discharge at BJ 3.10 from September 2014 through August 2016. Data are compared to the hydrological model used for the Mines Act and Environmental Management Act (MA/EMA) submissions.

All nitrate, nitrite and ammonia concentrations measured to date have remained below their respective discharge limits. Observed ammonia and nitrite concentrations are below MA/EMA predicted concentrations, with median values of 0.010 mg-N/L and 0.0030 mg-N/L, respectively (Figure 3-8). In contrast, observed nitrate concentrations are consistently higher than MA/EMA predicted levels, reaching a peak concentration of 1.22 mg-N/L in 2016. The reason for this is attributed to both nitrification processes occurring in the lake (described in Section 3.5) and model assumptions regarding loading rates.

With regards to nitrogen behaviour, the MA/EMA model assumed conservative behavior of nitrogen species in the lake with ammonia, nitrite and nitrate distributed as 14.8%, 4.2% and 81% of the nitrogen inventory in the lake, respectively. These assumptions are not consistent with observations, which show nitrate accounting for 95.2% (median) of the nitrogen load. This discrepancy between MA/EMA predictions and water measurements can be attributed to the occurrence of nitrification processes in the lake.

With regards to nitrogen loadings, analysis of the lake monitoring data indicates the overall nitrogen loading to Brucejack Lake is higher than the MA/EMA predictions, with the nitrogen inventory in the lake approximately 2-fold higher than predicted. The MA/EMA assumptions were derived from data sets available at the time which included published literature data sets for surface-blasted rock and Brucejack ML/ARD monitoring data collected prior to 2015. Revised predictions were developed based on recent monitoring data that are specific to the underground blasting conditions at the Brucejack Gold Mine. These revised loading estimates indicate that the original loading predictions underestimated total nitrogen losses from the mine.

Figure 3-8: Observed concentrations of nitrogen species at BJ 3.10 from September 2014 through August 2016. Data are compared to the Expected Case predicted values presented as part of the Mines Act and Environmental Management Act (MA/EMA) submissions.

3.4.2 Lake Water Column Data

Nitrogen species (nitrate, nitrite and ammonia) have been monitored in the Brucejack Lake water column since 2014 at station BJ 35, the deepest location in Brucejack Lake (80 m deep). The water column is sampled at seven depths (2, 7, 15, 38, 60, 70, and 80m). Water column monitoring data are shown for 2016 in Figure 3-9. Nitrate (NO_3^-) is the predominant form of nitrogen throughout the lake water column for all sampling events. From January through August 2016, the concentrations of nitrogen species at BJ 35 (over all depths) were generally non-detectable for ammonia ($NH_3 + NH_4^+$) and nitrite (NO_2^-). Peak concentrations for ammonia, nitrite and nitrate were 0.10 mg-N/L, 0.059 mg-N/L and 2.0 mg-N/L, respectively (70 m and 80 m depths), observed on August 25th 2016. These elevated signatures for ammonia and nitrite were confined to the lower depths of the lake, with trace or non-detectable levels measured near the lake surface.

Figure 3-9: Nitrate, ammonia and nitrite concentration profiles in the Brucejack Lake water column (Station BJ 35) from January through August, 2016.

3.5 Nitrification Processes occurring in Brucejack Lake

Empirical observations of lake water quality indicate that nitrification processes are active in Brucejack Lake. At the lake outlet, ammonia is depleted and nitrate is enriched relative to mine water. This shift favouring nitrate is consistent with the influence of nitrification processes on water quality. Nitrification reactions are mediated by bacteria (*e.g., Nitrosomonas* and *Nitrobacter*) that facilitate the oxidation of ammonia to nitrite, and the oxidation of nitrite to nitrate (Figure 3-10).

Figure 3-10: Oxidation of ammonia and nitrite by Nitrosomonas and Nitrobacter, respectively (Gerardi, 2002)

Nitrification reactions occur in mine water and in lake water and are mediated by microbial populations that oxidize ammonia and nitrite according to the processes outlined above. Sufficient residence time is required for nitrification processes to run to completion. Residence time in the underground workings is estimated to be approximately 12 hours, which appears to be insufficient time for nitrification processes to run to completion, as is reflected in the elevated proportion of ammonia (30%) in mine water relative to total nitrogen. The estimated residence time of effluent in Brucejack Lake is between 12 to 18 months. Lake water column monitoring provides empirical evidence that nitrification proceeds to near-completion, with ammonia representing only 2.3% (median) of the total nitrogen load at the lake outlet.

To support the conceptual model for nitrification processes, samples of underground mine water, mine slimes and lake water were collected and tested for nitrification bacteria. The test results presented in Table 3-4 indicate the presence of nitrifying bacteria at all locations.

Table 3-4:
Nitrifying bacterial test results for water and mine slime samples.

			#Bacterial Colony Forming Units (CFU)			
Sample	**Location**	**Bacterial Units**	**11 Dec 2014**	**06 Jan 2015**	**08 Mar 2015**	**07 May 2015**
Mine Slime	Underground Mine (1300 Ramp)	CFU/g	620	4100	5600	7700
Mine Water	Underground Mine (1300 Ramp)	CFU/100mL	0	79	280	10
Mine Water	Underground Mine at 1350 Sump	CFU/100mL	55	305	230	120
Lake Water	Lake Outlet at BJ 3.10	CFU/100mL	71	103	0	36
Creek Water	Creek at BJ 2.62	CFU/100mL	3	88	0	29
Control Sample (STP process water)	STP	CFU/100mL	542	2200	3200	2600
Control Sample (deionized water)	Field Blank	CFU/100mL	0	0	0	0

The updated water quality predictions presented below in Section 3.6 incorporate the conversion of nitrogen species due to nitrifying bacteria.

3.6 Updated Water Quality Predictions for Ammonia, Nitrite and Nitrate

Explosive use, mine and surface excavation volumes, as well as water quality data collected since September 2014, were analyzed to re-evaluate the nitrogen terms used in the MA/EMA water quality model. Based on this exercise, it was determined that nitrogen loadings from blasted rock surfaces to the lake were under-estimated. Further, the assumed nitrogen species distribution at the lake outlet did not account for nitrification processes that convert ammonia and nitrite to nitrate within the lake. Based on these considerations, the water quality predictions were revised to reflect:

1) Higher loading rates with respect to nitrogen compounds, based on monitoring data collected between September 2014 and April 2016; and
2) Non-conservative behaviour associated with secondary nitrification processes that convert nitrogen species in the lake, as inferred from the nitrogen species distribution at BJ 3.10.

Selected model terms were updated as shown in Table 3-5 for revised nitrogen species predictions. The Expected Case model scenario was calibrated to the January through April 2016 monitoring data, while the Upper Case was calibrated to the 2015 monitoring data.

Table 3-5:
Updated model terms for the revised water quality nitrogen (N) predictions. Updated terms are compared to the Expected Case and Upper Case terms presented as part of the Mines Act and Environmental Management ACT (MA/EMA) submissions.

		Expected Case		Upper Case	
Model Term	**Units**	**MA/EMA Model**	**Updated Model**	**MA/EMA Model**	**Updated Model**
Powder Factor (pF)	kg explosive / m^3 blasted rock	Construction: 3.24 Operations: 1.97	Construction: 4.15 Operations: 1.97	Construction: 3.24 Operations: 1.97	Construction: 4.15 Operations: 4.15
Excavation Schedule	m^3 blasted rock	Construction: MA/EMA plan Operations: MA/EMA plan	Construction: Nov. 2015 plan Operations: MA/EMA plan	Construction: MA/EMA plan Operations: MA/EMA plan	Construction: Nov. 2015 plan Operations: MA/EMA plan
Mine Water N Load	% of explosives used as N	4%	4%	8%	6%
Mine Water N species distribution	% of total nitrogen as N	Ammonia: 14.8% Nitrite: 4.2% Nitrate: 81%	Ammonia: 28.8% Nitrite: 5.2% Nitrate: 66%	Ammonia: 14.8% Nitrite: 4.2% Nitrate: 81%	Ammonia: 28.8% Nitrite: 5.2% Nitrate: 66%
Underground Waste Rock N Load	% of explosives used as N	5%	13%	10%	18%
Underground Ore N Load	% of explosives used as N	- [A]	13%	- [A]	18%
Lake Water N species distribution	% of total nitrogen as N	Ammonia: 14.8% Nitrite: 4.2% Nitrate: 81%	Ammonia: 4% Nitrite: 2% Nitrate: 94%	Ammonia: 14.8% Nitrite: 4.2% Nitrate: 81%	Ammonia: 4% Nitrite: 2% Nitrate: 94%

[A] In the MA/EMA water quality model, the ore source term was captured in the tailings term and expressed as kg/t of tailings, and is therefore not directly comparable to the revised term.

The Construction Phase excavation schedule was revised in November 2015 by Pretium to address delays with mine construction that resulted in a more compressed excavation schedule than originally planned. The total volume of waste that will be excavated during mine construction remains unchanged; however, the monthly waste volumes for the remainder of mine construction will be slightly higher than originally planned. The actual volumes excavated from September 2015 through August 2016, as well as the revised Construction Phase excavation schedule from September 2016 through May 2017, were included in the model.

The Construction Phase theoretical pF was increased by Pretivm in the November 2015 Construction Phase excavation schedule from 3.24 kg/m^3 to 4.15 kg/m^3. Actual rock

strength will vary from assumptions and will influence the amount of explosive required to fracture the blasted rock. It is typical for the pF to be adjusted based on *in-situ* ground conditions to achieve rock fragmentation objectives. As noted in Section 3.2.1, the pF achieved in 2015 was 4.0 m kg/m^3 increasing slightly to 4.5 kg/m^3 in 2016 (January through August), indicating the revised Construction Phase theoretical pF is appropriate from which to estimate explosive use for construction blasting. The mining of ore during the Operations Phase will be conducted using a different blasting technique (long hole blasting), which requires less explosives than used for mine construction. A theoretical pF of 1.97 kg/m^3 was used for the mine Operations Phase and represents the Expected Case condition. The actual pF will be adjusted based on ground conditions once mining begins, and may increase slightly. Accordingly, an Upper Case pF of 4.15 kg/m^3 (used for mine construction) was conservatively applied to the upper case scenario for the Operations Phase of the mine.

The mine water N load term has been carefully monitored and the Expected Case remains at 4 % of the explosives used (as N), in line with the 4.3% of explosives use observed from January through August 2016 (Section 3.2.1). However, the Upper Case N loss was reduced from 8 % of the explosives used to 6 % of explosives use. This corresponds to the 5.9% N loss that was observed in 2015, a time period that captured challenging blasting conditions and higher rates of N loss from explosives use.

The mine water species distribution previously used in the model was based on mine water monitoring data collected during mine exploration. The mine excavation rate increased significantly from January 2015 through August 2016, reaching the excavation rate expected during the Operations Phase. Therefore, the monitoring data from this time represents a more suitable proxy for modeling the nitrogen species distribution during the Operation Phase. The nitrogen species distribution median values from 2015 and 2016 (for mine water) were used to update the model.

The underground waste rock and ore N loading rates were increased from the previous model assumptions. The N loading rate associated with underground waste rock was previously determined from literature values for surface mining (Ferguson and Leask, 1988; Cameron, 2007; Baily, 2013) and ML/ARD field bin test results. Literature values for N loading to blasted rock in underground mines were not available, and therefore the model assumptions were based on the N loadings observed at surface mines. The N load for ore was originally predicted using supernatant data from metallurgical process bench tests conducted for the Brucejack Gold Mine Project. The actual N loads for waste rock were calculated using monitoring, blasting and excavation data for the January 2015 through April 2016 period, and equates to a loading rate of 18% of explosives used for 2015 and 12% of explosives used from January to April 2016. The observed N loading

rate more accurately represents the waste rock and ore N loading rates for underground blasting conditions at the Brucejack Gold Mine. Based on these site-specific observations, revised rates of 13% of explosives use (Expected Case) and 18% of explosives use (Upper Case) were included in the water quality model.

Previously, the mine water N species distribution was assumed for the lake outlet. However, monitoring data indicate nitrification processes are active in the lake converting ammonia and nitrite to nitrate. Based on observations at the lake outlet (BJ 3.10), the N species distributions were revised to 4%, 2% and 94% for ammonia, nitrite and nitrate, respectively, approximating the median values from 2015 and 2016.

Overall, the revised modeled nitrogen load to Brucejack Lake is approximately 5-fold higher than that presented as part of MA/EMA submission for both the Expected Case and Upper Case model scenarios. This increase in the modeled nitrogen loads are due to:

- An increase in the powder factor for Construction Phase excavation; and
- An increase in the N load on blasted rock surfaces (waste and ore).

Updated water quality predictions to 2035, and water quality observed to 2016, for the lake outlet (BJ 3.10), are shown in Figure 3-11. The Expected Case maximum values for ammonia, nitrite and nitrate are 0.22, 0.11 and 5.1 mg-N/L, respectively, while the Upper Case maximum values for ammonia, nitrite and nitrate are 0.49, 0.24 and 11.5 mg-N/L, respectively (Figure 3-11). The updated predictions for ammonia at BJ 3.10 are in a similar range as the Expected Case predictions presented as part of the MA/EMA (Figure 3-11). The MA/EMA model assumed conservative behaviour for ammonia, and therefore assigned a significant proportion of the nitrogen load to ammonia. Although the overall predicted nitrogen load has increased, ammonia represents a much smaller proportion of the nitrogen load in the updated predictions owing to the inclusion of non-conservative processes. Consequently, the revised ammonia predictions remain low.

The revised predictions for nitrate and nitrite show higher values in comparison to MA/EMA submission. This relates to both: 1) higher N loading rates associated with waste rock and ore; and 2) conversion of ammonia to nitrate through nitrification processes in Brucejack Lake.

The current discharge limits for ammonia, nitrite and nitrate are 1.0, 0.075 and 3.0 mg-N/L, respectively. Under the Expected Case scenario, nitrate is expected to exceed 3.0 mg/L in the summer of 2018, while nitrite is projected to exceed 0.075 mg-N/L in 2019. Ammonia is expected to remain well below the discharge limit of 1.0 mg-N/L for the duration of the project.

Figure 3-11: Water quality predictions for ammonia, nitrite and nitrate at BJ 3.10 from 2014 through 2035, and observed water quality from September 2014 through August 2016. The updated predictions replace previous predictions included with the Mines Act and Environmental Management Act (MA/EMA) Permits application.

4. Effects Assessment

4. Effects Assessment

4.1 Introduction

The updated predictions for nitrate and nitrite concentrations at the Brucejack Lake outlet (BJ 3.10) exceed the current discharge limits in Effluent Permit PE-107835 (Table 4-1). The current NO_3 discharge limit is equal to the generic long-term BC water quality guideline for the protection of freshwater aquatic life (BCWQG). The current NO_2 discharge limit represents an intermediate value between the short-term BCWQG (0.06 mg-N/L) and the Science Based Environmental Benchmark (0.18 mg-N/L) that was derived for Brucejack Creek in Appendix 7-Z of the MA/EMA Permits Application (Pretivm, 2014).

Table 4-1:
Maximum monthly average predicted concentrations of nitrate and nitrite compared to discharge limits at site BJ 3.10.

	Nitrate (mg-N/L)		Nitrite (mg-N/L)	
Model Case	**Maximum predicted**	**PE-107835 limit**	**Maximum predicted**	**PE-107835 limit**
Expected Case	5.1	3	0.11	0.075
Upper Case	11.5	3	0.24	0.075

The following sections provide a residual effects assessment of the updated predicted concentrations of nitrate and nitrite. The effects assessment method is the same as that used for the MA/EMA Permit Application, which assessed the geographic extent, ecological context, magnitude, duration, frequency, reversibility, and resiliency of potential ecological effects. These criteria were then used to determine the significance of potential effects and confidence in the significance rating.

4.2 Effects Assessment

4.2.1 Geographic Extent

The geographic extent of potential effects from elevated nitrate and nitrite are defined as waters with predicted concentrations greater than BCWQGs. Since BCWQGs are derived to be protective of all species and life stages to continuous exposure, concentrations that are less than the guideline are not predicted to cause toxic effects to aquatic life. Brucejack Creek is predicted to have concentrations of nitrate and nitrite greater than their respective BCWQGs.

Brucejack Creek flows into Sulphurets Creek (Figure 4-1). At site SC0 on Sulphurets Creek, immediately downstream of the confluence with Brucejack Creek, there is a minimum dilution of 8:1 (that is, a minimum of 8 parts Sulphurets water for every part of Brucejack water that flows into Sulphurets Creek) (ERM Rescan, 2014). This level of dilution will produce concentrations that are below BCWQGs for Expected Case and Upper Case predictions of NO_3, and for Expected Case NO_2 (Table 4-2). Upper Case NO_2 prediction would be diluted to 0.028 mg-N/L at 8:1 dilution, which is slightly above the BCWQG. A dilution of 12:1 would be required to produce NO_2 <0.020 mg-N/L in Sulphurets Creek. This level of dilution should be available most of the year at SC0, and would be achieved shortly downstream of SC0 during times of the year with minimum dilution.

Table 4-2:
Dilution required to equal BC Water Quality Guidelines in Sulphurets Creek

Parameter	Model case	BJ 3.10 (mg-N/L)	SC0 (mg-N/L)	BCWQG (mg-N/L)	Required Dilution
Nitrate	Expected Case	5.1	0.05	3.0	1:1
	Upper Case	11.5	0.05	3.0	3:1
Nitrite	Expected Case	0.11	0.001	0.02	5:1
	Upper Case	0.24	0.001	0.02	12:1

Based on the assessment that BCWQGs will be met in the headwaters of Sulphurets Creek, the geographic extent of the effects of assessment is therefore limited to Brucejack Creek for NO_3, and to site SC0 in Sulphurets Creek for NO_2.

4.2.2 Ecological Context

Brucejack Creek and most of Sulphurets Creek are non-fish-bearing streams. In Sulphurets Creek, the upper limit of fish distribution is defined by a fish barrier approximately 1.3 km upstream of the Unuk River confluence. Overall, the distance between the outlet of Brucejack Lake and fish habitat is approximately 20 km. No amphibians have been noted during ecological surveys of these streams. Aquatic life in these non-fish-bearing water courses is therefore limited to benthic invertebrates and periphyton.

Surveys in 2014 and 2015 of benthic invertebrate communities in Brucejack Creek show that the assemblage is composed predominantly of chironomids (midges) and oligochaetes (worms) (Figure 4-2). Other taxa were rarely captured. The highest relative percentage of other taxa was 9% Ephemeroptera (mayflies) at BJ0.27 in 2015, although it should be noted that total abundance of invertebrates at that station was low compared to other stations surveyed that year. Only chironomids were found at SC0, in both the 2014 and 2015 surveys. Periphyton surveys in Brucejack Creek have found algal slimes on rocks composed of chlorophytes and diatom species. Macroalgae were not present.

Figure 4-2: Benthic invertebrate community composition by major taxon as measured for 2014 and 2015 biological monitoring programs for Brucejack Creek and upper Sulphurets Creek. ND = no data.

4.2.2.1 Nitrate Toxicity

The long-term BCWQG for NO_3 of 3 mg-N/L was derived from a chronic toxicity endpoint of 30.1 mg-N/L for the pacific tree frog (*Pseudacris regilla*) and a safety factor of 0.1 (Schuyterma and Nebeker 1999). This guideline was supported by a study that measured a statistically significant developmental delay and reduced biomass in early life stage lake trout in water with 6.25 mg/L NO_3-N, and an uncertainty factor of 0.5 (McGurk *et al*. 2006). The fact that the BCWQG for NO_3 is derived from toxicity data for fish and

amphibians, which are not present in the streams being assessed, indicates that the NO_3 BCWQG may be overprotective of aquatic life.

Nitrate chronic toxicity data for invertebrates is summarized in Table 4-3. These data show that invertebrate species that are sensitive to NO_3 toxicity may be negatively affected at concentrations of 11 to 13 mg/L NO_3-N. These data may be representative of species of the orders Ephemeroptera (mayflies), Plecoptera (stoneflies) or Trichoptera (caddisflies) which are collectively known as EPT taxa and are considered to be sensitive to most contaminants. EPT taxa are uncommon in Brucejack Creek (Figure 4-2). The chronic toxicity endpoint for *Chironomus dilutus* (49 mg/L NO_3-N) is more applicable to Brucejack Creek benthic invertebrates communities, which are comprised of >90% chironomids and oligochaetes. NO_3 toxicity data for oligochaetes are not available.

Table 4-3:
Chronic nitrate toxicity endpoints for invertebrates

Species	Common name	Life Stage	Endpoint	Nitrate Effect Concentration (mg NO_3-N/L)	Reference
Ceriodaphnia dubia	Water flea	Neonates	7-d IC25 reproduction	11.3	Elphick 2011
Ceriodaphnia dubia	Water flea	Neonates	7-d LOEC* reproduction	43	Scott and Crunkilton 2000
Daphnia magna	Water flea	Neonates	7-d LOEC** reproduction	717	Scott and Crunkilton 2000
Hyalella azteca	Amphipod	Juvenile	14-d IC25 growth	12.9	Elphick 2011
Chironomus dilutus	Midge	3rd Instar	10-d IC25 growth	49.0	Elphick 2011

* Average of five replicate tests
** Average of two replicate tests
IC25 = Concentration that results in 25% inhibition of reproduction or growth
LOEC = Lowest Observed Effect Concentration

Toxicity to periphyton from NO_3 is unlikely, since NO_3 is a macronutrient required for algal growth. Indeed, growth media for culturing the types of algae that occur in Brucejack Creek (chlorophytes and diatoms) typically contain NO_3 levels >100 mg-N/L. Because NO_3 is a nutrient for periphyton, there is the potential that NO_3 from effluent discharge could stimulate the growth of algae in Brucejack Creek and cause a change to trophic status. This could occur only if other macronutrients required for growth, phosphorous in particular, are present. Dissolved orthophosphate concentration at BJ 3.10 has consistently been below its analytical detection limit (<0.001 mg/L) and is not expected to increase during mine operations. Accordingly, phosphorous limitation is expected to prevent enhanced growth of periphyton associated with predictions of NO_3 enrichment.

In summary, NO_3 toxicity data indicate that the Expected Case predicted NO_3 concentrations are one-half the concentration shown to produce chronic toxicity effects to sensitive invertebrates, therefore, no toxic effects from Expected Case predictions are expected. In contrast, the Upper Case NO_3 predictions are approximately equal to the level that has produced chronic toxicity to sensitive invertebrate species. However, species that may be sensitive to NO_3 toxicity (*e.g.*, EPT taxa) make up a small proportion (<10%) of the benthic invertebrate community in Brucejack Creek. Accordingly, the potential for chronic effects, such as reduced growth or reproduction, to the benthic invertebrate community is considered low. As well, benthic invertebrates in Brucejack Creek do not represent potential food for fish, which are not present for 20 km downstream of Brucejack Creek. Therefore, any minor impacts to sensitive taxa in Brucejack Creek would not be predicted to impact fish health.

4.2.2.2 Nitrite Toxicity

The BCWQGs (long- and short-term) for NO_2 were derived to be protective of salmonids. Rainbow trout are the most sensitive species in NO_2 toxicity tests (Nordin and Pommen, 1986). Nitrite toxicity data for invertebrates, which are the taxa representative of aquatic life in Brucejack Creek, are much less common than toxicity data for fish.

The U.S. Environmental Protection Agency contracted NO_2 toxicity testwork to fill in the gaps in toxicity data for invertebrates (USEPA, 2010) (Table 4-4). All tests were acute in nature, except for one test with *Ceriodaphnia dubia*, which produced acute (LC50=4.7 mg/L NO_2-N) and chronic (EC25=1.9 mg/L NO_2-N) toxicity endpoints (acute to chronic ratio (ACR) of 2.5). The lowest toxicity endpoint in this series of tests was an LC50 of 1.0 mg/L NO_2-N for the mayfly species *Amphinemura delosa*. Applying the ACR from the *C. dubia* tests, this translates to a chronic toxicity endpoint of 0.4 mg/L NO_2-N.

Table 4-4:
Chronic nitrite toxicity endpoints for invertebrates

Species	Common name	Endpoint	Nitrite Effect Concentration (mg-N/L)	Reference
Amphinemura delosa	Mayfly	96-h LC50 survival	1.0	USEPA, 2010
Hyalella azteca	Amphipod	96-h LC50 survival	1.5	USEPA, 2010
Ceriodaphnia dubia	Water flea	6-d LC50 survival	4.7	USEPA, 2010
Ceriodaphnia dubia	Water flea	6-d EC25 reproduction	1.9	USEPA, 2010
Chironomus dilutus	Midge	48-h LC50 survival	15.6	USEPA, 2010
Sphaerium simile	Fingernail clam	96-h LC50 survival	55.7	USEPA, 2010
Lampsilis siliquoidea	Fatmucket clam	14-d IC25 growth	177	USEPA, 2010

LC50 = concentration lethal to half the test population
EC25 = Concentration that results in 25% inhibition of reproduction or growth

In summary, the most sensitive invertebrate to NO_2 toxicity is a species of mayfly, which showed an acute toxicity endpoint of 1.0 mg-N/L, and a calculated chronic toxicity endpoint of 0.4 mg-N/L. The Expected Case prediction for NO_2 (0.11 mg-N/L) is four times lower than the most sensitive chronic toxicity endpoint, and the Upper Case prediction (0.24 mg-N/L) is one-half the most sensitive endpoint. The chironomid species tested was much less sensitive to NO_2 toxicity (LC50=15.6 mg/L NO_2-N). Overall, the data indicate that chronic toxicity is not expected to chironomids which make up the majority of benthic invertebrates in Brucejack Creek, nor to mayflies, which are uncommon in Brucejack Creek. Therefore, the ecological context of potential chronic effects to aquatic life in Brucejack Creek is considered low. As well, the ecological context at site SC0 in upper Sulphurets Creek from Upper Case predicted NO_2 concentration is low.

4.2.3 Magnitude, Duration, Frequency, Reversibility, and Resiliency

The magnitude of potential effects to aquatic life is low for both NO_3 and NO_2, since only the uncommon species of benthic invertebrates in Brucejack Creek have the potential for chronic toxicity from exposure to Upper Case predictions.

The duration of potential effects to aquatic life is long-term for both NO_3 and NO_2, since concentrations at the Brucejack Lake outlet are predicted to be elevated for years, until the end of the Operations Phase. The frequency of potential effects to aquatic life is constant, since NO_3 and NO_2 are predicted to be elevated throughout the year. The concentrations of NO_3 and NO_2 are predicted to return to baseline levels after use of explosives ends, during the Closure Phase, and therefore the potential effects are reversible.

The only aquatic life that may be affected by the predicted levels of NO_3 and NO_2 are benthic invertebrate communities in Brucejack Creek. The taxa that have been sampled during benthic invertebrate surveys are common in streams throughout British Columbia. Only the most sensitive taxa, such as mayflies and stoneflies, have the potential to show chronic toxicity associated with NO_3 or NO_2. Acute toxicity effects are not predicted to occur. EPT taxa should be highly resilient to potential chronic toxicity.

4.2.4 Significance of Potential Effects

The potential effects to aquatic life in Brucejack Creek and Upper Sulphurets Creek are considered Not Significant (Table 4-5). The low ecological context of potential effects to aquatic life in these streams is important in making this rating. Chronic toxicity data indicate that potential effects could occur only if the Upper Case NO_3 predictions are realized, and then only for the most sensitive benthic invertebrates, which make up a low proportion of the benthic assemblage. There is no potential for adverse effects to fish or

fish habitat. Also contributing to the Not Significant rating, is the small geographic extent of elevated NO_3 and NO_2 predictions, the low magnitude of potential effects, and the highly resilient nature of benthic invertebrate communities.

Table 4-5:
Residual effects criteria ratings for nitrate and nitrite predictions

Criterion	NO_3 Rating	NO_2 Rating	Comment
Geographic extent	Local	Local	Restricted to Brucejack Creek, and upper Sulphurets Ck. only for Upper Case NO_2 prediction.
Ecological context	Low	Low	No effects predicted to fish, fish habitat, or uncommon species.
Magnitude	Low	Low	Upper Case predictions are equal to (NO_3) or less than (NO_2) levels that could cause chronic toxicity to the most sensitive invertebrates.
Duration	Long-term	Long-term	NO_3 and NO_2 will be elevated throughout the Operations phase of mining.
Frequency	Constant	Constant	Predicted concentrations are relatively constant throughout the year.
Reversibility	Reversible	Reversible	NO_3 and NO_2 levels will return to baseline levels when use of explosives ceases.
Resiliency	High	High	The benthic invertebrates in Brucejack Lake are common throughout British Columbia
Likelihood	Medium	Low	Chronic toxicity from NO_3 is only likely for the Upper Case predictions, and only to the most sensitive benthic invertebrates. Chronic toxicity from predicted NO_2 levels is unlikely.
Significance	Not significant	Not significant	The low ecological context, combined with the other criteria ratings, make the potential for effects to aquatic life not significant.
Confidence	High	High	There is high confidence in the updated nitrogen predictions, and sufficient toxicity data in the literature to rate the ecological effects criteria with high confidence.

5. Conclusions and Recommendations

PRETIVM

5. Conclusions and Recommendations

5.1 Conclusions

Conclusions from this assessment are as follows:

- Residues from explosives used in underground mining were the primary source of nitrogen loading to Brucejack Lake and are primarily associated with underground waste rock and to a lesser degree mine water. Surface waste rock deposition has been a minor contribution and the STP effluent load has been negligible.
- The empirical data acquired between January and April 2016 indicate that the nitrogen loading rate for underground blasted rock to Brucejack Lake is 12% of explosives use as N. This is significantly higher than the literature-based value previously assumed in the MA/EMA Permits Aplication (i.e., 5% of explosives as N). Data presented in the NMP indicates best practices were implemented throughout the monitoring period and therefore this magnitude of nitrogen loss from explosives is expected under normal blasting conditions at Brucejack Gold Mine.
- Empirical evidence indicates nitrification processes are active in Brucejack Lake, depleting ammonia and reducing nitrite levels, and increasing nitrate concentration. The occurrence of nitrification processes is supported by monitoring data that have identified nitrifying bacteria in site matrices (water and sediment) and bench experiments showing nitrification can be induced in ammonia-amended lake waters.
- Nitrification processes in the lake water column are expected to continue through the life of mine and beyond, with nitrate expected to account for more than 95% of the total nitrogen inventory at the lake outlet (BJ 3.10).
- Revised water quality predictions for the Construction and Operations phases incorporate the updated nitrogen loading and speciation information obtained from monitoring data, and show maximum nitrate concentrations of 5.1 mg-N/L (Expected Case) and 11.5 mg-N/L (Upper Case). The maximum values for nitrite are 0.11 mg-N/L (Expected Case) and 0.24 mg-N/L (Upper Case). The current discharge limits for ammonia, nitrite and nitrate are 1.0, 0.075 and 3.0 mg-N/L, respectively. Nitrate is expected to exceed 3.0 mg/L in the summer of 2018 and nitrite is projected to exceed 0.075 mg-N/L in 2019. Ammonia is expected to remain below the discharge limit of 1.0 mg-N/L for the duration of the project.
- Predicted nitrate values at BJ 3.10 are not predicted to cause chronic toxicity to aquatic life in Brucejack Creek or upper Sulphurets Creek. Upper Case nitrate

predictions may cause chronic toxicity to a small proportion of the benthic invertebrate community in Brucejack Creek. Upper Case nitrate predictions will have no adverse effects to fish, fish habitat, or uncommon species. The potential for residual effects from predicted nitrate concentration is considered not significant.

- Predicted nitrite concentrations at BJ 3.10, for both the Expected and Upper Cases, are not predicted to results in chronic toxicity to aquatic life in Brucejack Creek or upper Sulphurets Creek. The potential for adverse effects from predicted nitrite levels is considered not significant.

5.2 Recommendations

Overall, the results provided herein have important implications with regards to nitrite management. The following recommendations are proposed:

- The nitrogen species distribution is controlled by processes occuring in Brucejack Lake. Treatment of nitrite in the WTP effluent is unlikely to influence the concentration of nitrite at the lake outlet. Nitrogen loading is controlled through implementation of the NMP which sets out source control practices and monitoring. It is recommended the discharge limit for nitrite in WTP effluent be removed.
- Nitrate and nitrite are predicted to exceed the current discharge limits and may reach levels of 11.5 mg-N/L and 0.24 mg-N/L, respectively. The biological effects assessment determined that potential adverse effects to aquatic life in Brucejack Creek and Sulphurets Creek from the maximum predicted concentrations are not significant. Therefore, these levels are considered protective of the aquatic life and are recommended as discharge limits at the BJ 3.10 monitoring station.

6. Closure

6. Closure

We trust that this report meets your expectations at this time. Please contact the undersigned with any questions or comments.

ACKNOWLEDGEMENTS

This Nitrogen Management Plan (NMP) was prepared for Pretium Resources Inc. (Pretivm) by Lorax Environmental Services Ltd. (Lorax). The Management Plan was written by Patrick Mueller BSc, PChem, with assistance of Justin Stockwell, MSc, and Neil Mallen, MSc, EP. Input from Pretivm senior management was provided by Kevin Torpy, Lyle Morgentaler and George Friesen.

GLOSSARY AND ABBREVIATIONS

Terminology used in this document is defined where it is first used. The following list will assist readers who may choose to review only portions of the document.

ANFO	Ammonium Nitrate Fuel Oil
BCM	Bench Cubic Metre
CWP	Contact Water Pond
EMS	Environmental Management System
NMP	Nitrogen Management Plan
NPAG	Not Potentially Acid Generating
O&M	Operation and Maintenance
PAG	Potentially Acid Generating
pF	Powder factor (kg explosive / BCM)
STP	Sewage Treatment Plant
N	Nitrogen
WTP	Water Treatment Plant

1 PURPOSE

The purpose of this Nitrogen Management Plan (NMP) is to provide guidance for Pretium Resources Inc. (Pretivm) on how to avoid, minimize and otherwise mitigate the release of waterborne nitrogen compounds (*i.e.*, ammonia, nitrite, and nitrate) to the receiving environment. These compounds are primarily generated from explosives used during mining operations and to a lesser degree from the discharge of treated domestic wastewater. The procedures used for explosives handling, blasting, contact water management, blasted rock handling, and the treatment of domestic wastewater throughout life of mine are identified or described in the NMP.

2 SCOPE

Source control is generally recognised as an effective strategy for nitrogen mitigation and this is implemented at Brucejack Gold Mine through administrative controls and the implementation of best practices for explosive handling and blasting, as well as domestic wastewater management. Secondary mitigation includes the evaluation and implementation of water treatment as necessary and practicable. The monitoring data collected through the NMP are used to evaluate and update the water quality prediction model source terms for ammonia, nitrite and nitrate.

Specifically, this NMP addresses the following activities:

- Use of best practices for explosives use and domestic wastewater management;
- Establishment of performance targets for the monitoring and management of nitrogen compounds;
- Training programs;
- Monitoring, recordkeeping and corrective action programs;
- Program reviews, evaluation of effectiveness, and implementation of improvements;
- Evaluation of secondary mitigation strategies, as necessary; and,
- Verification of the nitrogen prediction water quality model, as required.

The NMP applies to all individuals working for or on behalf of Pretivm, including employees and contractors who have a role and/or accountability for the development, implementation and maintenance of this NMP.

3 LEGISLATION AND REGULATION

This NMP has been developed in accordance with applicable legislation, regulations and guidelines. Planning for environmental protection is a requirement of both the B.C. *Mines Act* (1996) and the Health, Safety and Reclamation Code for Mines in British Columbia (MEM, 2008). The movement, storage, use and disposal of explosives at mines in B.C. are regulated pursuant to Part 8 of the Code.

Development of a formal NMP is required by Section D.1 of the Brucejack Mine Permit M-243 issued by the Ministry of Energy and Mines under the BC *Mines Act* (1996). The Permit requires that a NMP be prepared as part of an overall EMS and implemented. Section D.5 of the Permit requires that

updates to the water quality prediction model be prepared by July 31, 2020 and every five years thereafter. Discharge of waste from a mine requires authorization pursuant to section 120 (3) of the BC *Environmental Management Act* (2003) and is administered at Brucejack Gold Mine by the BC Ministry of Environment (MOE) under Effluent Permit 107835. An NMP is required under Section 3.2 of the Permit. Treated domestic wastewater is regulated under the BC *Municipal Wastewater Regulation* (Reg. 87/2012).

The *Federal Explosives Act* (R.S.C., 1985, c. E-17) and *Explosives Regulations* (SOR/2013-211) regulate the manufacture, movement, storage, use and disposal of explosives Canada-wide. The BC *Spill Reporting Regulation (*BC Reg. 263/90), issued pursuant to the *Environmental Management Act* (2003), establishes reporting requirements for spills of substances, both as defined in the *Schedule – Reportable Levels for Certain Substances* included in the Regulation. The *Federal Fisheries Act* (R.S.C., 1985, c. F-14, as amended) indicates the release of ammonia, nitrate and nitrite products into fish-bearing waters may constitute deposition of a deleterious substance, as defined in Section 36(3) of the Act. Federally, the discharge of mine effluent is regulated by the *Metal Mining Effluent Regulations* (MMER; SOR/2000-222), issued pursuant to sections 34(2), 36(5), and 38(9) of the Act.

Field sampling must be undertaken in accordance with the *British Columbia Field Sampling Manual for Continuous Monitoring and the Collection of Air, Air-Emission, Water, Wastewater, Soil, Sediment and Biological Samples* (BC MWLAP 2003), and laboratory analyses must be completed in accordance with the *British Columbia Laboratory Manual* (2013 Approval holder Edition; BC MOE 2013).

4 NITROGEN SOURCES AND CONTROLS

4.1 Overview

Residual explosive is a recognized source of ammonia, nitrate and nitrite in adit discharge, surface runoff, and blasted rock surfaces. Nitrogen constitutes approximately 30% of the explosive mixture, apportioned almost equally between ammonia (NH_3 and NH_4^+) and nitrate (NO_3^-) as N, while nitrite (NO_2^-) is an intermediate oxidation product of ammonia. Treated domestic wastewater is also a source of ammonia and nitrate, however this represents a small proportion of the nitrogen load discharged to Brucejack Lake. Water soluble nitrogen compounds are transported to the aquatic environment downstream of Brucejack Mine through discharge from Brucejack Lake at station BJ 3.10.

The Project will generate approximately 1.7 Mm^3 of waste rock from the Mine Site, 1.7 Mm^3 of waste rock from the underground mine and 6.2 Mm3 of ore. Blasting residuals associated with rock excavation can mobilize during the following situations:

- Underground blasting;
- Surface blasting;
- NPAG fill deposition;
- Waste rock storage/deposition; and,
- Ore storage/processing.

Nitrogen residues are exported from blasted rock on the blasted rock surfaces and in the contact water. The mine water is routed through a water treatment plant prior to discharge to Brucejack Lake, whereas waste rock is deposited directly to the lake. Surface contact water from the mill and plant site is diverted to a contact water pond; CWP water is directed to the WTP for treatment prior to discharge to the lake (during mine operations it will be directed to mill process as needed). Contact water may also be discharged directly to Brucejack Lake if the water quality meets WTP discharge limits. Quarry fill is used for road and mill site construction.

4.2 Nitrogen Sources

4.2.1 Explosive Handling and Blasting

The explosive used for underground blasting is an ANFO-emulsion product, TITAN® 7000 Sensitized Bulk Emulsion from Dyno Nobel. Packaged ANFO-Emulsion products are used for surface blasting including DynoNobel BlastGel 1000/1070 or Blastex. Limited amounts of Unimax, a packaged nitroglycerin based explosive, is used for small scale surface blasts.

Handling of explosives is restricted to trained and authorized personnel only. All explosive movements are communicated and traffic control measures are implemented as necessary to minimize accident risk during transport. Explosives are loaded into blast holes with the boosters and detonators; however, detonator tie in is conducted just prior to a blast. Protocols for best blasting practices are listed in Appendix A and Appendix B.

4.2.2 *Explosives Storage Area*

Explosives are stored in restricted areas that are secure and locked, and access is limited to authorized personnel only. Storage conditions are maintained clean and dry. Permanent explosives magazines are located at multiple locations on the mine site and in the underground. Access to the areas is controlled by lock. The four surface magazines are located along the access road at 53 km (2), 71.4 km (1) and 73.2 km (1) and detonators for surface blasting are stored in two magazines at 71.6 km and 73 km. In the underground mine the packaged emulsion products are stored in the WZ 1350 level and bulk emulsion and spoiled explosives are stored in a secured VOK drift. Inventory is used on a first-in, first-out basis to ensure quality control and prevent degradation due to storage. Spoiled explosives are disposed by detonation during the firing of a round during regular blasting operations.

4.2.3 *Rock and Ore Handling*

Waste rock is removed from the underground for disposal in Brucejack Lake. As the mine develops some waste rock will be returned to the underground mine as backfill. Ore is moved to a temporary stockpile for processing in the Mill. Supernatant water from the mill process is discharged to the lake. Surface blasting occurs at the NPAG Quarry and during the Construction Phase at the PAG Mill Site. Quarry rock is used for fill and Mine Site rock is disposed subaqueously in the lake.

Visible non-detonated explosive in the muck pile or in the blasted rock is removed and disposed according to safe disposal practices.

4.2.4 *Explosive Loss Predictions*

A loss of nitrogen from explosive use is normal and expected during blasting operations. For underground operations the overall nitrogen loss rates is on the order of 15% of the explosives used for blasting. Approximately one third of the nitrogen is exported in mine water, and the remaining two thirds remain on the blasted surfaces. The estimates for explosives loss to mine water and the muck pile are summarised in Table 4-1 below. Loss rates were derived using data from underground and surface mining operations (Brucejack Gold Mine monitoring data from January , 2015 through April, 2016 for underground blasting; and, Ferguson and Leask (1988) for surface blasting).

Table 4-1: Explosive losses reporting to Brucejack Lake

		Explosive Loss Rate [1,2]	Destination
Underground Blasting			
	Mine water	4%	Lake
	Underground waste rock storage	13%	Lake
	Underground waste rock backfill	13%	Mine
Surface Blasting			
	NPAG quarry surface runoff	2%	Lake
	NPAG deposition surface runoff	1%	Lake
	Mine Site surface runoff	1%	Lake
	Mine Site waste deposition	2%	Lake

[1] Estimated percentage loss of total explosives used for blasting.
[2] The nitrogen content in the ANFO emulsion products is estimated at 29.7% N assuming an explosive composition of ammonium nitrate (76%), sodium nitrate (12%), mineral oil (7%), and glass oxide (5%).

4.2.5 Treated Domestic Wastewater

Domestic wastewater is treated by the packaged Filterboxx waste water treatment plants using a process that includes a membrane bio-reactor, activated aerobic sludge, membrane clarification and UV disinfection prior to discharge. Two of the plants have a rated treatment capacity of 75 m^3 per day, and the third has a rated capacity of 25 m^3 per day, for a total of 175 m^3 per day maximum discharge of treated domestic wastewater to Brucejack Lake. The plants are operated in accordance with Effluent Permit PE-107835. Maximum predicted discharge levels of nitrate, nitrite and ammonia are presented in Table 4-2. The nitrogen added to the lake from treated domestic wastewater is a small proportion of the total amount when blasting is accounted for, therefore the STPs are not considered for further source control measures.

Table 4-2: Wastewater (Sewage) Treatment Plant Environmental Impact Assessment predicted effluent concentration

	STP effluent
Ammonia (mg N/L)	55
Nitrite (mg N/L)	1
Nitrate (mg N/L)	2

4.3 Source Control

Source control measures are implemented to reduce nitrogen loss from explosives use and to establish mitigation strategies. Source control measures for explosives use and blasting are outlined in Table 4-3 below. Domestic wastewater is treated prior to discharge as described in Section 4.2.5.

Table 4-3: Explosives handling and blasting nitrogen control measures

Activity	Nitrogen Control Measures
Explosive Selection	• Select water resistant explosives appropriate for site conditions
Blast pattern design	• Design patterns to achieve desired fragmentation with minimum explosives use
Blast hole loading	• Dewater blast holes • Used package explosive for flowing holes • Minimize "sleep" time after explosives have been loaded
Water management	• Divert water away from and/or blast holes and contact surfaces

4.4 WTP Effluent and Nitrite Treatment

Mine water and CWP water are routed though the WTP for the removal of solids and dissolved metals prior to discharge. The WTP capacity during the Construction Phase is 6,000 m^3 and this capacity will increase to 10,000 m^3 during the Operations Phase.

Nitrite treatment is a contingency measure and is generally inactive unless certain trigger conditions are met. Trigger conditions are adjusted throughout the year in accordance with WTP effluent quality and to achieve discharge limits in Effluent Permit 107835.

The monitoring of explosives loss to mine water is summarized in Appendix C.

4.5 Secondary Nitrification Processes

WTP discharge is to Brucejack Lake. Natural nitrification processes appear to be active in the lake, converting almost all nitrogen to the nitrate form. Nitrification reactions are controlled by bacteria and can both create and remove nitrite through the oxidation of ammonia to nitrite, and the oxidation of nitrite to nitrate. These reactions can occur in mine water and in the receiving environment and are mediated by distinct the microbial communities *Nitrosomonas* and *Nitrobacter* as indicated in Figure 6-1 below.

Figure 4-1: Oxidation of ammonia and nitrite by *Nitrosomonas* and *Nitrobacter*, respectively (Gerardi, 2002)

Nitrogen compounds are released at the blast face into contact water. Microbial populations in the underground and surface systems oxidize ammonia and nitrite according to the processes outlined above. Sufficient residence time is required for nitrification processes to run to completion. The anticipated residence time of effluent in the lake is estimated at 12 to 18 months, and lake water

column monitoring provides empirical evidence that nitrification proceeds to completion in the lake water column.

Water based drill fluid can contain biocides that may affect the populations of nitrification bacterial populations in mine water and/or the treatment plant. All drilling additives are reviewed for the presence of bactericides that may inhibit or alter nitrification processes prior to approving their use.

5 NMP IMPLEMENTATION

5.1 Overview

The NMP is implemented with staff training, performance monitoring and management oversight. The monitoring data are regularly reviewed to detect trends and initiate corrective actions as necessary. Personnel are trained regarding the environmental impacts of explosive use and industry best practices for source control. The NMP is regularly reviewed and updated in response to monitoring data and changes in requirements.

5.2 Training, Awareness and Competence

Personnel and contractors involved with explosives handling and use are trained to understand the scope and mechanism of environmental impacts of explosive use. Performance evaluation and follow-up training is provided to relevant personnel to help achieve implementation of best practices.

Work procedures are documented, reviewed and updated to address the following:

- Work practices described in the Health, Safety and Reclamation Code for Mines in British Columbia, Part 8 (2008);
    - Observe the work practices of subordinates on an ongoing basis; and,
    - Take action to correct practices that deviate from best practices.
- Documentation of blasting practices are kept on site with Pretivm and blasting contractors, and describe:
    - Handling, transportation and storage of explosives;
    - Preparation and loading of blast holes;
    - Blast safety protocols;
    - Procedures after blasting; and,
    - Best practices for nitrogen management.

5.3 Performance Monitoring and Reporting

Nitrogen loss performance monitoring is conducted using explosives use and water quality data and is outlined in Table 5-1 below. An internal explosives loss target has been established to detect excessive loss of explosives. The Water Treatment Plant (WTP) effluent performance objectives are specified in Effluent Permit 107835. The monitoring of mine water, CWP water and WTP effluent for nitrogen species is conducted through in-line sensors, on-site field tests and external accredited laboratory analyses. Ammonia and nitrite concentrations are monitored daily to ensure discharge objectives are consistently met. The nitrogen contribution from treated domestic wastewater is compared to the predicted values (refer to Section 4.2.5).

Table 5-1: Performance objectives for nitrogen management

	WTP effluent	BJ 3.10
Explosive loss to mine water (%)	4 [A]	-
Ammonia (mg N/L)	-	1.0
Nitrite maximum / annual mean (mg N/L)	1.9 / 0.65	0.075 / -
Nitrate (mg N/L)	-	3

[A] This is an internal objective only; refer to Appendix C for a summary of WTP monitoring data.

The monitoring data are summarized in daily, weekly and monthly reports that are distributed for review to the Senior Mine Engineer, Environmental Manager and other key individuals (Table 5-2). External reporting of external laboratory results is required via annual reporting. Site monitoring is not required to be submitted, however, records must be maintained and provided for regulatory review if requested by an applicable regulatory agency.

Table 5-2: Summary performance monitoring reports

Report	What is tracked
Blast Report (Daily)	Drilling/blasting records for a given pattern • Hole depth, explosives use, blasted volume/advance • Other activities (*i.e.*, shotcrete, water management, spills, etc.)
Rock Movement Report (Daily)	Waste rock placement records • Surface rock volumes • Underground rock volumes
UG Summary Report (Monthly)	Year to date summary of UG blasting metrics • explosive use, volume blasted, slimes/cuttings moved, shotcrete use
WTP Report (Daily)	Daily performance and effluent quality • report on key performance metrics for WTP operation • metrics include ammonia and nitrite monitoring
WTP Meeting Notes (Weekly)	Water management and WTP Operation • Mine engineer, environmental staff, WTP technician and other expertise as required • WTP performance, mine water quality, CWP water quality, and issues influencing water quality in the water management system

5.4 Inspections

Routine inspections are conducted of the water management systems underground and on surface. The checklists provided in Appendix A and Appendix B are used for evaluation of blasting practices.

Other checklists are developed as needed to target specific control measures. Inspection reports are maintained; corrective actions are identified for implementation.

5.5 Investigation and Corrective Action

Incidents pertinent to nitrogen management are investigated, documented and analyzed to identify root cause. Incident reports are prepared by Pretivm environmental staff and submitted to the Environmental Manager. The reports will include:

- Description of the incident;
- Investigation and assessment of root cause; and,
- Corrective actions.

Corrective actions are implemented in accordance with this plan and reviewed for effectiveness. If further improvements are necessary, these are tracked with the original incident report. The Environmental Manager is responsible to ensure that the corrective actions are tracked until an incident is considered to be addressed. Relevant records are summarized for annual reporting.

5.6 Emergency Procedures and Response

Emergency response procedures related to explosives use are prepared by the blasting contractor. Emergencies are immediately communicated to the Pretivm emergency response coordinator, and response plans and activities are coordinated with Pretivm.

5.7 Management Review

The NMP monitoring activities and results are summarized in reports for regular review by the Senior Mine Engineer and the Environmental Manager. Where improvements are needed agreed upon actions will be implemented.

The overall implementation and effectiveness of the NMP is formally reviewed at least annually with all relevant parties. The Senior Mine Engineer leads the review and includes the Mine Superintendent, The Environmental Superintendent, and all contractors who conduct blasting. Reviews include observation of work practices, review of SOPs, monitoring records, training records, monitoring reports and an overall evaluation of the implementation of the NMP. Review reports are provided to the Senior Mine Engineer and include:

- Review of explosives use, and summary of environmental and audit reports;
- Summary of interviews of the mine, environmental, engineering and blast crews;
- Summary of observed explosives handling and blasting practices; and,
- Action items arising from the review process.

Action items arising from the review process are assigned to the appropriate individuals and tracked for future evaluation.

APPENDIX A – SURFACE BLASTING PROTOCOLS

There are numerous considerations for surface blasting that may either enhance or reduce explosive consumption efficiency. Outlined below are typical situations that can reduce explosive consumption efficiency and increase the amount of residual nitrogen compounds available for waterborne export from the mine site.

Consideration	Description
Pattern design.	The blast pattern should be designed to meet rock fragmentation objectives considering specific pattern geometry and geo-mechanical rock properties. The pF target is based on the minimum amount of explosive required to meet the fragmentation objectives.
Wet site conditions.	The presence of water in the blast pattern creates challenging site conditions that that affect the amount of nitrogen released to the environment. Explosives appropriate for wet conditions must be used (*i.e.,* ANFO-emulsion). Water must be managed to direct surface flows away from blast holes and to dewater groundwater from the pattern.
Explosive quality.	Poor explosive quality (*i.e.,* out of specification composition) may cause inefficient consumption, and in extreme cases failure to detonate, leading to poor blast performance and increased residue of nitrogen compounds.
Powder column contamination.	This occurs when water or sediment (i.e., drill hole cuttings) are mixed into the powder column. Sediment and water can cause bridging when one part of the powder column is separated from the remaining powder column thereby preventing propagation of the explosion reaction through the column.
Fractures and voids.	Loading explosives into boreholes with fractured rock or voids will result in explosives loading of empty spaces adjacent to the blast hole. Explosives connected to the powder column but confined to small spaces will deflagrate leading to the formation of yellow/orange smoke (nitrous oxides).
Detonation Failure.	The powder column will not detonate if the detonator and booster are outside of the explosive or if the detonator is cut prior to detonation.
Spills.	Spills can collect between blast holes due to leakage from the transfer hosing/connections, or by dripping out of the hose as the hose is moved away from the loaded blast hole. All spills must be removed prior to blasting.
Improper stemming.	Stemming material should be angular coarse crush with a size approximately 1/10th of the blast hole diameter (Floyd, 2011) in order to effectively contain the blast energy. Insufficient stemming or use of improper material for stemming (i.e., borehole cuttings) will fail to contain the blast energy within the blast hole.
Improper decking.	Decking aids with the propagation of the blast energy through the blast pattern and can also be used to isolate the powder column from void spaces and fractured rock. Poorly formed seals will allow the leakage of explosive into empty spaces below the seal, with the seal forming a bridge in the powder column and preventing detonation of the leaked explosive below the seal.

APPENDIX B - UNDERGROUND BLASTING PROTOCOLS

There are numerous considerations for underground blasting that may either enhance or reduce explosive consumption efficiency. Outlined below are typical considerations for improving explosive consumption efficiency and reducing the amount of residual nitrogen compounds available for waterborne export from the mine site.

Consideration	Description
Pattern design	The blast pattern should be designed to meet rock fragmentation objectives considering specific pattern geometry and geo-mechanical rock properties. The pF target is based on the minimum amount of explosive required to meet the fragmentation objectives.
Wet site conditions	The presence of water in the blast face creates challenging blast conditions that that affect the amount of nitrogen released to the environment. Explosives appropriate for wet conditions must be used (*i.e.,* ANFO-emulsion).
Explosive quality	Poor explosive quality (*i.e.,* out of specification composition) may cause inefficient consumption, and in extreme cases failure to detonate, leading to poor blast performance and increased residue of nitrogen compounds.
Powder column contamination	This occurs when water or sediment (*i.e.,* drill hole cuttings) are mixed into the powder column during blast hole loading. Sediment and water can cause bridging when one part of the powder column is separated from the remaining powder column thereby preventing propagation of the explosion reaction through the column.
Fractures and voids	Loading explosives into boreholes with fractured rock or voids will result in explosives loading of empty spaces adjacent to the blast hole. Explosives connected to the powder column but confined to small spaces will deflagrate leading to the formation of yellow/orange smoke (nitrous oxides).
Detonation Failure	The powder column will not detonate if the detonator and booster are outside of the explosive or if the detonator chord is cut prior to detonation.
Spills	Spills can occur at the blast face due to leakage from the blast hole or by dripping out of the hose as the hose is moved between blast holes. All spills must be removed prior to blasting. Waste explosive must be collected before and after detonation to minimize N loss to the adit water and muck pile.

APPENDIX C – EXPLOSIVES LOSS TO ADIT WATER

The loading of nitrogen to mine water from explosives use from January 2015 through August 2016 was compared to expected values (Figure A.3-1 below). During this period the mine excavation rate increased from approximately 1,400 m^3/week in January 2015 to approximately 9,700 m^3/week in August 2016, corresponding to 2,200 kg/week and 35,000 kg/week of explosives consumption, respectively. The nitrogen load from explosives to mine water is expected to be 4% of the explosives use (as N), this is the rate observed during the Exploration Phase of Brucejack Gold Mine.Mine. Mine dewatering flows ranged from approximately 3,000 m^3 to 15,000 m^3 per week during this period and the measured N load exported in the mine water over this monitoring period increased from approximately 30 kg-N/week to 400 kg-N/week.

Figure A.3-1: Weekly flows and nitrogen loads predicted from explosive use, and nitrogen loads measured in the WTP effluent (January 2015 through April 2016)

Overall the measured N loads were in the range of expected N loads, except during May 2015 and September/October 2015 when anomalous peak nitrogen loads of 150 kg N/week and 420 kg N/week, respectively, were observed. The short duration increases in the mine water N load were attributable to increased nitrogen losses due to blasting through water bearing structures with significant flows at the blast face; these are challenging blasting conditions that are known to increase the N loading rate from the explosives.

The average loading of N to the mine water in 2015 was 5.9% of the explosives used (as N), and this includes periods of higher than expected N loading to mine water. From January through August 2016 the average N loading rate to mine water was 4.3% of the explosives used (as N), and the comparison of measured and expected loads indicates explosives losses were well controlled through this period.

Executive Summary

PRETIVM

Executive Summary

This report provides updated water quality predictions in support of an application by Pretium Resources Inc. (Pretivm) to increase the allowable Brucejack Gold Mine ore production rate from an annual average 0.99 Mt to 1.387 Mt (*i.e.,* average 2700 tpd to average 3800 tpd). Specifically, Pretivm is applying to amend Brucejack Gold Mine *Mines Act* Permit M-243 and *Environmental Management Act* Effluent Permit 107835 as required to authorize the production increase. The updated water quality predictions also reflect a slight increase in the mine ore reserves, from 16.5 Mt for the 2015 MA-EMA Permits Application, to 18.5 Mt. The increase in the ore production rate will reduce the mine life from 18 years as predicted in 2015 to approximately 14 years, with the ore reserve increase slightly offsetting the mine life reduction.

Revisions to the Brucejack Gold Mine water quality model for the production increase application include the incorporation of revised flows from the updated 3800 tpd water balance model, changes to the mine waste schedules, and updates to geochemical source terms based on new data and trends observed in the monitoring data sets. In general, source terms have been developed based on geochemical data sets following a similar approach to that outlined in the 2015 MA-EMA Permits Application. Where possible, operational monitoring data sets have been used for source term development in lieu of static test data sets. Notable updates to the water quality model include:

- Addition of a term to account for stored loads associated with waste rock placed on the waste rock pad for up to two years;
- Revision to the approach for developing blasting-related N loads and the assumed N species distribution in Brucejack Lake;
- Development of a post-depositional diffusional term asssociated with the co-deposition of sludge with tailings in Brucejack Lake; and
- Incorporation of post-depositional As and Sb loads associated with the placement of waste rock in Brucejack Lake.

As part of the production increase application, Pretivm is also seeking authorization for the flexibility to direct waste rock to either Brucejack Lake or as backfill in the underground mine, depending upon operational needs. Two model scenarios for waste deposition were developed to reflect the extremes for waste rock deposition, based on an approach that if the modelled results for the extremes are acceptable, any ‘in-between’ waste deposition would also be acceptable. In the first scenario (Scenario 1), all of the waste rock (5.3 Mt) and 50% of the tailings (8.7 Mt) generated through the operational mine phase would be

placed in Brucejack Lake and the remaining tailings (8.7 Mt) would be backfilled in the underground mine. In the second scenario (Scenario 2), two thirds of the waste rock (3.4 Mt) would be backfilled in the underground mine, with the remainder (1.9 Mt) placed in Brucejack Lake. Consequently, significantly less tailings would be backfilled as paste in the underground mine (5.5 Mt; 32% of total generated). Model updates were completed for both of these mine waste management scenarios.

This report presents Base Case and Upper Case water quality predictions for both scenarios at station BJ 3.10, the mine's regulated discharge point located at the outlet of Brucejack Lake, and station BJ 2.62, a downstream monitoring location in Brucejack Creek. The Base Case is considered to represent a conservative expected case; whereas the Upper Case incorporates the combined effects of upper case geochemical source terms for all inputs.

Water quality model results at BJ 3.10 and BJ 2.62 for the proposed production increase are generally similar to those presented in the 2015 MA-EMA Permits Application; however, concentrations of a few parameters are predicted to increase above the previous maximum predicted concentrations. For Base Case BJ 3.10 water quality predictions, these are: ammonia, nitrite, nitrate, dissolved aluminum (D-Al), total antimony (T-Sb), total arsenic (T-As), dissolved iron (D-Fe), total lithium (T-Li) and total selenium (T-Se); whereas, for Base Case BJ 2.62 water quality predictions, these are ammonia, nitrite, nitrate, chloride (Cl), fluoride (F), D-Al, T-Sb, T-As, D-Fe, total iron (T-Fe), T-Li, T-Se, total uranium (T-U) and total zinc (T-Zn). Despite these increases, the only parameters predicted to exceed PE-107835 discharge limits or applicable BC FWAL guidelines are ammonia, T-Sb, T-As, T-Fe, D-Fe and T-Zn.

The water quality predictions presented for the two waste rock and tailings management scenarios (*i.e.,* Scenario 1 and Scenario 2) show similar trends with most parameters showing only minor differences. It is noted that the maximum Base Case predictions for some parameters are lower in Scenario 1 (*e.g.,* sulfate, silver, zinc), whereas for others they are lower in Scenario 2 (*e.g.,* ammonia, nitrite, nitrate, arsenic). Overall, the results indicate that whichever waste management strategy is implemented will have minimal influence on water quality in the receiving environment.

Parameters of potential concern were identified from both production increase application modelling scenarios and include all those with predictions that are (1) higher than in the 2015 MA-EMA Permits Application, and (2) higher than a PE-107835 discharge limit during Operations (arsenic) <u>or</u> BC FWAL guideline during Closure or Post-Closure (ammonia, antimony, arsenic, iron, and zinc).

Base Case ammonia concentrations at BJ 3.10 are predicted to increase above the PE-107835 discharge limit (1.0 mg/L) early in Operations and remain elevated until the

Closure phase when blasting and waste rock deposition have ceased. Base Case ammonia concentrations at both BJ 3.10 and BJ 2.62 are predicted to decrease to background levels by the end of the Closure phase.

Base Case As predictions for the production increase modelling are similar to the 2015 MA-EMA Permits Application, but the timing of the maximum Operations predictions is earlier in the mine life with the updated mine schedule. The updated model has As exceeding its discharge limit of 5 µg/L in year 2 of Operations, whereas the 2015 MA-EMA Permits Application predicted an exceedance in Year 6. Updated Closure and Post-Closure predictions for As are slightly lower than in the 2015 MA-EMA Permits Application.

The updated Base Case Sb model predicts Sb concentration will be above the BC FWAL working guideline during much of the Operations phase. Antimony is predicted to decrease during Closure phase, and be lower than the guideline during Post-Closure. The pattern is the same presented in the 2015 MA-EMA Permits Application, with maximum prediction Base Case prediction being 13 µg/L in the updated model and 9 µg/L in the 2015 application, which is equal to the BC FWAL guideline.

Iron and Zn concentrations are predicted to exceed respective water quality guidelines at BJ 2.62 during the Closure and Post-Closure phases when the underground mine is flooded and groundwater flows to Brucejack Creek. The predicted elevated Fe concentrations are expected to decrease below BC FWAL guideline limits when solubility constraints are considered. Zinc is predicted to have a maximum concentration of 8.6 µg/L, a slight increase from the maximum of 8.5 µg/L in the 2015 MA-EMA Permits Application, and slightly above the BC FWAL guideline of 7.5 µg/L.

Residual effects from the maximum predicted concentrations of ammonia, As, Sb, Fe, and Zn were assessed. No adverse effects from ammonia, As, Sb, or Zn were predicted, and the assessment gave a low significance rating to potential effects from Fe. The effects ratings were based on toxicity literature that showed that no toxicity is expected to aquatic life in the receiving environment. As well, site specific toxicity testing of As and Sb found that the predicted concentrations are below the No Observable Effects Level to an algal species that is known to be sensitive to arsenic toxicity.

Iron in groundwater entering Brucejack Creek during Post-Closure is predicted to be insoluble in the creek and to precipitate out. Since water is expected to have Fe concentrations below the BC FWAL guidelines, no significant effect to aquatic life from dissolved Fe is expected. Sediment Fe concentrations may increase and may have a localized effect on benthic organisms. The overall significance of iron precipitation is considered low.

Discharge limits based on Operations phase Upper Case BJ 3.10 predictions have been proposed for ammonia (4 mg-N/L), T-Sb (28 µg/L) and T-As (10 µg/L). The Base Case model results represent monthly average concentrations, whereas the Upper Case predictions are expected to capture the variability arising from samples that are greater than the monthly average. The effects assessment indicates that the proposed ammonia, T-Sb and T-As discharge limits will not cause significant adverse effects to aquatic life in the receiving environment.

Potential cumulative effects in lower Sulphurets Creek from the proposed ammonia, Sb and As discharge limits and water quality predictions for the KSM mine are considered not significant. The maximum loading of ammonia, T-Sb or T-As from Brucejack Mine effluent would not cause the cumulative concentration to go above the BC FWAL water quality guidelines, or to change the background concentration when the background levels are above the guideline.

1. Introduction

1. Introduction

This report has been prepared in support of an application by Pretium Resources Inc. (Pretivm) to amend Brucejack Gold Mine *Mines Act* Permit M-243 and *Environmental Management Act* Effluent Permit 107835 to allow an increase in ore production rate from the currently permitted average annual 990,000 t on a calendar basis to average annual 1.387 Mt. This equates to an increase from an average ore production rate of 2700 tpd to 3800 tpd. The Brucejack Gold Mine is located approximately 65 km NNW of Stewart, B.C. (Figure 1-1) and began producing gold in June 2017.

The proposed 3800 tpd mine operating life is approximately 14 years, with a total ore reserve of 18.5 Mt. Pretivm is seeking the flexibility, based on operational needs, to direct future waste rock to either Brucejack Lake for subaqueous deposition, or to the underground mine for backfilling of secondary stopes. The 3800 tpd applications include assessments of the two extremes (scenarios) for waste rock deposition (*i.e.*, maximum deposition according to either method), with tailings discharge and paste backfill balanced accordingly. The intent of this approach is that if both extremes are acceptable for a given type of assessment, any 'in between' deposition ratio would logically also be acceptable.

Specifically, in Scenario 1, all future waste rock (5.3 Mt) would be deposited in Brucejack Lake along with approximately 50% of the tailings. The remaining 50% of tailings would be deposited in the underground mine as paste backfill. In Scenario 2, approximately two-thirds of the waste rock (3.4 Mt) would be deposited underground, with an associated increase in the percentage of tailings deposition in the lake (68%).

The purpose of this report is to predict how the proposed change in ore production rate (*i.e.*, the mill processing rate) will impact water quality in the receiving environment through life of mine (LOM) and into the Post-closure phase, considering both scenarios. Water quality modelling results are presented for two stations: 1) BJ 3.10, the mine's regulated discharge location; and 2) BJ 2.62, a downstream monitoring location in Brucejack Creek which will receive underground mine loads via groundwater pathways once the mine has been flooded following closure (Figure 1-1). Results for BJ 3.10 were generated for the Operations, Closure and Post-closure mine phases; whereas water quality results at BJ 2.62 were only produced for the Closure and Post-closure phases.

This report also describes revisions to the water quality model that were presented in the 2015 MA-EMA permits application and subsequently updated in amendment applications for increased nitrite and nitrate discharge limits (submitted November 2016), co-deposition of water treatment plant sludge with tailings (submitted January 2017), extension of the

PAG waste rock exposure time criterion (submitted January 2017) and approval of an updated Cr Management Plan (submitted February 2017). These revisions include updates to various source terms based on new data, the incorporation of new terms based on trends observed in the monitoring data sets, changes to the mine plan schedules, and revisions to water management plans. In general, source terms have been developed based on geochemical data sets following a similar approach to that outlined in the 2015 MA-EMA Permits Application. However, where possible, operational monitoring data sets have been used for source term development in lieu of static test data sets.

Following this introduction, Chapter 2 describes the modelling approach and assumptions used in the generation of the water quality predictions. Chapter 3 describes the water quality model source terms for the various background and mine-related inputs. The model results for Base Case and Upper Case predictions are presented in Chapter 4, with an environmental effects assessment of the water quality predictions provided in Chapter 5. The report concludes with a summary of the results (Chapter 6).

2. Modelling Approach and Assumptions

PRETIVM

2. Modelling Approach and Assumptions

This chapter describes the modelling approach and assumptions associated with updating water quality predictions for the Brucejack Gold Mine for an increase in ore processing rate (from 2700 tpd to average daily 3800 tpd). Mitigation strategies are outlined, followed by a detailed description of the water quality modelling approach.

2.1 General Site-Wide Mitigations

Water quality predictions presented in this report include consideration of several mitigation strategies. For the purpose of water quality modelling, it is assumed that the proposed mitigations will be effective as designed. These mitigations include:

- A Sewage Treatment Plant (STP) which will meet effluent quality discharge requirements throughout life of mine (LOM). Treated water is discharged to Brucejack Lake;
- Management of contact water, via collection ditches, pipelines and related structures, as per the Water Management Plan;
- An Operations Water Treatment Plant (WTP) which will treat contact water from the site and meet effluent quality discharge requirements throughout LOM. Treated water is discharged to Brucejack Lake;
- Management of potentially acid generating (PAG) waste rock through deposition of waste rock into Brucejack Lake. It is assumed that suspended sediments associated with the waste rock will continue to largely settle in the lake, which acts as a natural sedimentation pond. It is further assumed that any sediments remaining in suspension will be managed using the sediment control curtains;
- Disposal of thickened tailings solids and effluent to the bottom of Brucejack Lake via a suspended tailings pipeline; it is assumed that fines associated with tailings will continue to remain at the bottom of the lake, similar to natural fine grained sediment;
- Management of blasting-related nitrogen compunds following source control measures and best management practices as outlined in the Nitrogen Management Plan (NMP); and
- Management of hexavalent chromium associated with cement use in the underground mine as described in the Chromium Management Plan (CMP).

2.2 Water Quality Model

2.2.1 Overview

The Brucejack Gold Mine water quality model employs a mass balance approach that accounts for background water quality and runoff volumes reporting from undisturbed portions of the Brucejack Creek watershed, as well as chemical loads emanating from mine sources (*e.g.*, underground workings, waste rock, tailings discharge) and water management structures (*e.g.*, Contact Water Pond (CWP), the WTP and the STPs). Loads associated with solids such as deposited waste rock, explosive-related nitrogen species and tailings, were pre-determined and input directly to the mass balance calculations. Each component of the existing environment and Mine Site Area that may contribute to water quality at the outlet to Brucejack Lake (BJ 3.10; model node 1) and at Brucejack Creek monitoring station BJ 2.62 (model node 2) has been included in the water quality model.

Background water quality signatures are derived from pre-Construction monitoring (ERM Rescan, 2014), while mine-related water quality signatures are based on geochemical source terms. The water quality model was constructed in accordance with the structure of the water balance for the Brucejack Gold Mine (BGC, 2018). The water balance model tracks all background and mine-impacted waters that report to Brucejack Lake and various monitoring sites (model nodes) along Brucejack Creek. An overview of the water balance is provided in Section 2.2.2, with additional information on derivation of the water balance provided in the water balance update (BGC, 2018).

The water quality model assumes the lake is vertically stratified for most of the year, but fully mixed during months when the lake experiences temperature-driven turnover events (July and October). This assumption is supported by lake profiling data collected through monitoring programs developed for Brucejack Lake (described in Section 2.2.5).

The water quality model was developed in GoldSim; a flexible, object-oriented software tool that is designed for carrying out dynamic, probabilistic simulations of complex systems. GoldSim can be applied to deterministic simulations in which all inputs are pre-determined by the user. This approach was used to predict water quality concentrations at mixing locations within the conceptual flow networks defined for each of the specified mine phases.

The model uses monthly time steps throughout the duration of mine life and includes a total of 372 consecutive months, consisting of:

- Exploration phase: 32 months, from January 2013 through August 2015, which corresponds to the last 2 ½ years of the exploration period. Calibration predictions

were assessed between February 2013 and March 2014 using observed measurements from that period;

- Construction phase: 21 months, from September 2015 through May 2017, which corresponds to the two-year Construction phase (*i.e.*, Y-2 (September 2015 through May 2016) and Y-1 (June 2016 through May 2017));
- Operations phase: 163 months, from June 2017 to December 2030, which corresponds to the expected timing and duration of the 14-year Operations phase (Note that Y1 is defined as June 2017 to December 2017, whereas all years thereafter are based on a calendar year);
- Closure phase: 36 months, from January 2031 to December 2033, which corresponds to the estimated timing and duration of the Closure phase; and
- Post-closure phase: 120 months, from January 2034 to December 2043, which corresponds to the first 10 years of the Post-closure period.

The predicted monthly flows in the water balance model vary through the year, reflecting site hydrology and hydrogeology. Site data acquired during the Exploration and Construction phases were used to calibrate and validate the water quality model. The water quality model results presented here reflect predictions for the Operations, Closure and Post-closure phases; however, chemical loads associated with Construction phase activities have been incorporated into the model since a portion of these loads will impact Brucejack Lake water quality during the first few years of Operations (as determined by the residence time in the lake, which is estimated to be approximately 18 months).

An underpinning assumption of the modelling approach is that parameters behave in a conservative manner and that no mass is lost through geochemical reactions or natural biogeochemical processes. In this regard, water quality predictions result solely from the mixing of the various water types. This results in significant conservatism in the model, since some degree of removal is expected from secondary reactions. In the underground environment, for example, some degree of attenuation can be expected through adsorption and mineral solubility constraints. In Brucejack Lake, various natural biogeochemical mechanisms are also expected to attenuate trace element and nutrient concentrations (*e.g.*, biological uptake of nitrogen and phosphorus and metal scavenging by particles and removal to lake sediments). Attenuation processes are not modelled, but the distribution of nitrogen among inorganic species (*i.e.*, ammonia, nitrite and nitrate) is adjusted to account for nitrification processes that occur naturally in Brucejack Lake.

2.2.2 Water Balance

The water balance and water management plans for the Brucejack Gold Mine were developed by BGC Engineering (BGC, 2018). The water balance is a detailed interpretation of the mine and water management plans, with consideration of baseline climate, hydrometric, and hydrogeological data collected for the Mine Site Area (*i.e.*, the area that comprises all mine infrastructure to the west of Knipple Glacier). The present section presents an overview of the water balance provided by BGC (BGC, 2018) which has been integrated into the water quality model described above.

The water balance for the Brucejack Gold Mine was derived using information from the following sources:

- Mine schedules for waste rock, ore and tailings;
- Underground mine design and mill feed rates;
- Site-specific and long-term climate dataset for the proposed mine area, including precipitation, potential evaporation and temperature;
- Drainage areas and runoff coefficients;
- Estimated groundwater inflows and seepage rates;
- Process plant water balance model (including freshwater make-up requirements); and
- Tailings density and properties.

The water balance configurations for the Operations and Post-Closure phases used to develop the water quality model are illustrated in Figure 2-1 and Figure 2-2 respectively.

The following are the main water management components of the water balance for the Operations phase:

1. A CWP which receives approximately 70% of surface runoff from the Mine Site contact water management area (primarily the mill and camp pads). This water is pumped to the WTP for treatment. The remaining 30% is assumed diversion ditch leakage that reports directly to the lake;
2. Dewatering from the underground mine, which includes groundwater inflows, and paste backfill bleed water (*i.e.*, the excess water not consumed in the paste backfill cementation reaction);
3. The WTP, which treats water from the CWP and the underground mine. The treated effluent is used in the mill process, with any excess not required for process discharged to Brucejack Lake in an effluent discharge line line along with STP effluent. WTP

effluent used in process is also discharged via the tailings line as part of the tailings slurry;

4. Two STP units which discharge to Brucejack Lake via the WTP/STP effluent line;
5. A mill which discharges a tailings slurry to Brucejack Lake and pipes paste backfill to the underground mine;
6. The conveyance of contact flows from the NPAG Quarry to Brucejack Lake via surface runoff; and
7. Deposition of waste rock subaqueously in Brucejack Lake, and to the underground mine as backfill.

The operational components of the Brucejack Gold Mine are summarized in Figure 2-1, along with other water inflows and losses relevant to the Operations phase water balance. Monthly average lake discharges during operations are expected to range from 0.046 to 1.5 m^3/s. These discharge flows include the contribution of water displaced by the deposition of waste rock and tailings solids. Total lake water volume capacity at the start of operations is 29.5 Mm^3 and is reduced to 22.2 Mm^3 at the end of operations.

At Closure, mine facilities will be decommissioned (*e.g.*, STP, WTP, and mill) and the underground mine workings will be flooded. The reconfiguration of flows and the associated water management plan is reflected in the water balance illustrated in Figure 2-2.

The Post-closure water balance includes the following mine-related components:

- Flows from the NPAG Quarry;
- Flows from the reclaimed plant site; and
- Drainages from the underground mine which flow to Brucejack Lake and Brucejack Creek via groundwater pathways.

In addition to accounting for mine-related loads, the water quality model predictions incorporate contributions from Camp Creek and the Mine Site surrounding background.

Figure 2-1: Brucejack Lake Water Balance Model Schematic for the Operations Phase.

Figure 2-2: Brucejack Lake Water Balance Model Schematic for the Post-closure Phase.

2.2.3 Modelling Locations and Parameters

Water quality predictions are generated for two locations, also termed model nodes (Figure 1-1):

- BJ 3.10, located at the outlet to Brucejack Lake; and
- BJ 2.62, a monitoring station in Brucejack Creek, located downsteam of Brucejack Lake.

During the Operations phase, Brucejack Lake receives all mine-affected inputs, and thus monitoring station BJ 3.10 at the outlet to the lake was selected as the mine's regulated discharge point for Operations, and is the point at which discharge limits in Effluent Permit 107835 apply.

During the Post-closure phase, once the mine is flooded, the majority of groundwater flow paths from the underground mine discharge to the upper reaches of Brucejack Creek between the lake outlet and BJ 2.62. Monitoring station BJ 2.62 is located downstream of Brucejack Lake and Camp Creek at the bottom of a cascade, which is expected to result in fully mixed conditions upstream of BJ 2.62. BJ 2.62, therefore, represents a key location for the Post-closure water quality predictions.

Water quality predictions were generated for the parameters listed in Table 2-1, including major ions representative of mine-related inputs and all parameters with BC freshwater aquatic life (FWAL) guidelines. Neither pH nor TSS was modelled, as they depend on a wide range of factors that are not fully accounted for in the mass loading approach.

Table 2-1:
Water Quality Parameters Included in the Brucejack Gold Mine Water Quality Model

Parameter	Formula
Major Anions	
Ammonia (as N)	NH_3-N
Nitrate (as N)	NO_3-N
Nitrite (as N)	NO_2-N
Chloride	Cl^-
Fluoride	F^-
Sulfate	SO_4^{2-}
Phosphorus	P
Metals (Total and Dissolved)	
Aluminum	Al
Antimony	Sb
Arsenic	As
Barium	Ba
Beryllium	Be
Bismuth	Bi
Boron	B
Cadmium	Cd
Calcium	Ca
Chromium	Cr
Cobalt	Co
Copper	Cu
Iron	Fe
Lead	Pb
Lithium	Li
Magnesium	Mg
Manganese	Mn
Mercury	Hg
Molybdenum	Mo
Nickel	Ni
Phosphorous	P
Potassium	K
Selenium	Se
Silicon	Si
Silver	Ag
Sodium	Na
Strontium	Sr
Thallium	Tl
Tin	Sn
Titanium	Ti
Uranium	U
Vanadium	V
Zinc	Zn

2.2.4 Water Quality Modelling Cases

Water quality predictions through Operations, Closure and Post-closure mine phases were generated for a Base Case and an Upper Case. The Base Case represents a conservative expected condition, whereas the Upper Case applies upper case geochemical source terms to all mine-related inputs to the model. Both cases are based on average flow conditions for all flows with the exception of groundwater flows during the Operations phase. The water quality model applies the low hydraulic conductivity (K) groundwater flows as presented in the site water balance, since these flows are more consistent with the groundwater flows observed to date.

Both Base Case and Upper Case conditions were modelled for the two proposed mine scenarios:

- **Scenario 1:** All waste rock generated from the underground mine is placed in Brucejack Lake. This scenario maximizes the amount of tailings that are placed as paste backfill in the underground mine.
- **Scenario 2:** The amount of waste rock placed as backfill in the underground mine is maximized to the extent possible with the remaining portion placed in Brucejack Lake. This scenario results in a higher proportion of tailings being placed in Brucejack Lake.

Mine schedules were developed for both scenarios and are presented in the relevant source term sections below.

2.2.5 Mixing Assumptions for Brucejack Lake

Northern lakes are typically dimictic, meaning that they mix from the surface to the bottom twice per year due to convective overturn in the spring and fall. This behaviour applies to Brucejack Lake, which becomes stratified during the summer and winter months (lower density surface layer on top of a higher density lower layer). The water quality model assumes that Brucejack Lake is dimictic, being fully mixed in July and October and stratified during other months.

The model assumes that the surface layer is represented by the upper 10 m of the lake and that the lower layer extends from a depth of 10 m to the lake bottom. The upper 10 m of Brucejack Lake contains approximately 25% of the total lake volume. Modelled loadings to the surface layer are from background runoff, uncaptured Mine Site runoff, and NPAG Quarry runoff. Modelled loadings to the lower layer are from waste rock deposition, WTP discharge, STP discharge, and tailings disposal.

The model assumptions regarding lake mixing behaviour are supported by 2016-2017 temperature and density monitoring data sets collected throughout the water column (Figure 2-3). Strong stratification is observed through winter and late summer months, whereas the lake is fully mixed in July and October.

Figure 2-3: Vertical profiles of temperature and density in Brucejack Lake during different seasons of 2016-2017.

2.3 Summary of Updates to the Water Quality Model

The water quality model has been revised since it was presented in the MA-EMA Permits Application (Pretivm, 2015). These revisions include updates to various source terms based on new data, the incorporation of new terms based on trends observed in the monitoring data sets, changes to the mine plan schedules, and revisions to water management plans. The major revisions incorporated into the current water quality model include the following:

- Revision to the site's water balance based on observed flows and changes to the mine plan (described in BGC, 2018); a more detailed understanding of flows and recycling processes within the mill has resulted in changes to the configuration of the GoldSim model with respect to calculation of tailings and bleed water source terms;

- The addition of a term to account for stored loads associated with waste rock placed on the waste rock pad for up to two years;
- The development of a post-depositional diffusional term asssociated with the co-deposition of sludge with tailings in Brucejack Lake;
- Revision to Cr loads associated with paste backfill and bleed water based on new kinetic tests results;
- The incorporation of post-depositional As and Sb loads associated with the placement of waste rock in Brucejack Lake;
- Revisions to the approach for developing blasting-related N loads and the assumed N species distribution in Brucejack Lake;
- Refinement of assumptions related to water quality during the flooding period of the underground workings at Closure; and
- Re-calibration of lake water quality based on water quality monitoring data sets collected in July 2017 when the lake is assumed to have been fully mixed.

3. Source Terms

3. Source Terms

The Brucejack Gold Mine water quality model incorporates the combined effects of all background (non-contact) and mine-related (contact) sources. The water quality predictions presented in Chapter 4 are based on source terms developed for the following components:

- Background sources;
- NPAG Quarry runoff;
- Mine Site runoff;
- Waste rock and weathered material from surface excavations deposited in Brucejack Lake;
- Underground Mine waste rock placed in Brucejack Lake;
- Underground Mine water;
- Water Treatment Plant effluent and solid phase sludge;
- Tailings deposited in Brucejack Lake and placed in the underground mine as paste backfill;
- Sewage Treatment Plant effluent; and
- Blasting-related nitrogen compounds.

The derivation of source terms for each of these components is described in the following sections. In most cases, source terms are based on static and kinetic geochemical data sets following the same approach as described in the MA-EMA Permits Application. However, where possible, source term updates have incorporated recent operational data sets acquired through the various site monitoring programs. The observed Brucejack Lake water quality has been used to validate the model inputs, but has not been used for direct calibration except in the case of N species.

All source terms are updated on an annual basis and comparisons to previous values are presented in the Annual Reports. Water quality model source terms will be refined as additional operational data sets are acquired and these revisions will be incorporated into the 5 year Mine Plan and Reclamation Plan (due June 2020).

3.1 Background Water Quality

3.1.1 Overview

Background (non-contact) water quality terms for the Brucejack Gold Mine are based on monitoring datasets for Brucejack Lake and Camp Creek, as measured at stations BJ 3.10 and CC 0.01, respectively (ERM Rescan, 2014). The BJ 3.10 dataset reflects the cumulative influence of background precipitation, evaporation, groundwater, and surface runoff to the lake, and also accounts for waste rock deposited in Brucejack Lake, and any other activity that may have impacted water quality, up to the completion of baseline monitoring in 2013. The Camp Creek data set was used to calculate a background source term for BJ 2.62. The flows assigned to the background source terms are based on the water balance provided by BGC (described in Section 2.2.2).

Brucejack Lake is situated within the Brucejack Creek watershed and receives water from an area of approximately 6.6 km^2. Beyond the lake, a relatively small volume of undisturbed surface flow and groundwater report to Brucejack Creek between the outlet to Brucejack Lake and downstream monitoring station BJ 2.62. Background water quality specific to this small catchment is not available. Consequently, this flow was assigned chemistry values equal to the background terms used for Brucejack Lake, as a conservative proxy recognizing that these values include the influence of waste rock dumping and other mine inputs to Brucejack Lake.

3.1.2 Background Source Term Values

The source term for Brucejack Lake was developed using baseline monitoring data collected between 2009 and 2013, when Pretivm was conducting advanced mineral exploration in the Brucejack Valley. While periods of exploration during the 2009 to 2013 monitoring period may have affected BJ 3.10 water quality (*e.g.*, waste rock dumping required from underground exploration; ERM Rescan, 2014), the relative effect of including such events in source-term calculations is small and ultimately yields a more conservative source term for modelling purposes. Monitoring data collected by Newhawk between 1987 and 2001 (n = 56 samples) had several limitations (*e.g.*, high method detection limits, limited number of parameters analyzed), making it unsuitable for use in source term development.

The monitoring data were grouped into quarters (three-month long periods) to reflect distinctive seasonal hydrologic phases at the site. At the Brucejack Gold Mine, site conditions are most consistent with three-month periods that are shifted one calendar month forward, relative to normal calendar quarters. The background source term values

were therefore calculated by applying a "Smart Quarters" approach using the following time intervals:

- Smart Quarter 1: February, March, and April;
- Smart Quarter 2: May, June, and July;
- Smart Quarter 3: August, September, and October; and
- Smart Quarter 4: November, December, and January.

Background water quality source terms were calculated from median values for each Smart Quarter dataset (Table 3-1) and applied to both the Base Case and Upper Case models.

Background water quality for BJ 2.62 incorporates the added contributions from Camp Creek based on the data sets available for time periods when Camp Creek was considered to be uninfluenced by exploration and/or mine-related activities (*e.g.*, October 2009-June 2012 and January 2016-present). The Camp Creek data used for calculation of the BJ 2.62 background values are presented in Table 3-2, and represent median values for each of the Smart Quarter intervals described above. The calculated BJ 2.62 background values used in the water quality model are provided in Table 3-3.

Table 3-1: Background (Brucejack Lake and Upper Brucejack Creek) Source Terms for Base Case Scenario

3.2 NPAG Quarry

3.2.1 Overview

Approximately 730 kt of rock has been excavated from the NPAG Quarry to provide material for building foundations, roads and other construction activities at the Mine Site. The NPAG Quarry is located near the southeast end of Brucejack Lake and runoff from the NPAG Quarry flows into Brucejack Lake. The NPAG Quarry is comprised predominantly of volcanic (plagioclase-hornblende) porphyry, with lesser amounts of conglomerate (S3), and negligible sulfide mineralization. Results from the preliminary ML/ARD characterization (Pretivm, 2015) and subsequent confirmatory sampling programs (Pretivm, 2016a; 2017) confirm that rock excavated from the NPAG Quarry is consistently NPAG with low neutral metal leaching potential. Runoff source terms were developed to capture contributions from drainage in contact with exposures in the NPAG Quarry.

3.2.2 NPAG Quarry Runoff

Shake flask extraction (SFE) tests carried out on rock samples collected from the NPAG Quarry were used to predict the quality of surface drainages from the NPAG Quarry. Median and 90th percentile values of the cumulative SFE results for 52 samples were used to represent Base Case and Upper Case source terms, respectively. A comparison of the SFE data with leachate quality from a conservative representative field kinetic test and runoff water quality samples demonstrate that the SFE data provide the most conservative approximation of neutral metal drainage from the NPAG Quarry exposures. The concentration values assigned to NPAG Quarry runoff flows as designated by the site water balance are presented in Table 3-4.

3.3 Mine Site

3.3.1 Overview

A total of ~1,500 kt of waste rock and 165 kt of weathered surface material were excavated from the Mine Site surface area to support the construction of site roads and pads for various facilities including the mill, Phase 2 Camp and CWP. Construction of the Mine Site was initiated in September 2015 and continued during 2016, with the majority of excavation occurring in Q1 and Q2 of 2016.

Geochemical source terms were developed for 1) Mine Site run-off associated with exposures from surface excavation; 2) Mine Site surface waste rock deposited in Brucejack Lake; and 3) weathered surface material placed in Brucejack Lake. For waste rock placed in Brucejack Lake, instantaneous and post-depositional loads have been calculated. The instantaneous surface waste rock load represents the mass of available soluble constituents that are instantaneously released into solution. The post-depositional loads represent the longer-term loads released following deposition of the waste rock in Brucejack Lake. The approach for derivation of each of these water quality model inputs are described in the sections below.

3.3.2 Mine Site Runoff

Contact water associated with runoff from the Mine Site will be collected by the contact water collection system, which directs water to the CWP. Non-contact surface runoff from areas immediately surrounding the Mine Site will be directed to Brucejack Lake via the East (Johnson Creek) Diversion Channel, and to Camp Creek via the West (Camp Creek) Diversion Channel. The Mine Site runoff source term includes runoff from all exposed rock units at the Mine Site.

A block model was developed by Pretivm for the Mine Site excavation area based on the five geologic units identified through surface mapping and drilling campaigns. These units are: ANDX (intermediate fragmental volcanic rock), VSF (volcanic sedimentary facies), P2 (K-feldspar bearing porphyry), P1 (plagioclase-hornblende bearing porphyry) and S3 (conglomerate). The surface waste rock units are similar to those found in the underground mine, but have slightly different metal contents and acid base accounting (ABA) characteristics. Consequently, surface materials were characterized independent of the underground block model units. The rock units exposed as a result of these excavations include ANDX, VSF, P2, P1 and S3.

SFE results from 92 lithology-specific samples were used to predict loads to Brucejack Lake from surface run-off at the Mine Site. The Base Case and Upper Case values were

derived using median and 90th percentile values for the complete dataset as presented in Table 3-5.

3.3.3 Surface Waste Rock

A summary of the lithology-specific surface waste rock excavation work carried out during Construction is provided in Table 3-6. Preliminary ML/ARD characterization designated three out of the five geologic model units for surface waste rock as NPAG based on median NPR values; however, the NPR values are very close to the PAG threshold value of 2 (2.0, 2.4 and 2.6 for the S3, P2 and ANDX units, respectively). The majority of the VSF and P1 samples are characterized as PAG with NPR values generally <2. Results from confirmatory sampling of these units are consistent with the preliminary characterization. Thus, surface-blasted Mine Site waste rock was generally classified as PAG and all was managed through sub-aqueous deposition in Brucejack Lake. A discussion of the preliminary geochemical assessment and confirmatory sampling is summarized in the Annual Reports (Pretivm, 2016a; 2017).

Table 3-6:
Tracked Mine Site Waste Rock Tonnages Placed in Brucejack Lake During Construction

3.3.3.1 Instantaneous Loads

Lithology-specific SFE data sets were used to predict the instantaneous loads from Mine Site surface waste rock deposited in Brucejack Lake. Source terms presented in the MA-EMA Permits Application (Pretivm, 2015) were developed using the projected waste rock schedule and SFE data from the preliminary characterization of the Mine Site surface waste rock lithologies. Since that time, additional confirmatory SFE samples have been collected. The revised source terms for instantaneous loads to Brucejack Lake from submerged Mine Site waste rock incorporate all the available SFE data and utilize the tracked waste rock tonnages deposited in Brucejack Lake during the Construction phase.

Monthly loads were scaled to account for the proportion of waste rock considered to be reactive (*i.e.*, soluble) using the fraction of material that is < 6.4 mm, or approximately 20% of the total waste rock. Revised Base Case and Upper Case source terms were calculated from the cumulative dataset using the 75th and 90th percentile lithology-specific SFE values and the scaled monthly waste rock excavation tonnages (Table 3-6). The revised source terms for Base Case and Upper Case are summarized in Table 3-7 and Table 3-8, respectively.

3.3.3.2 Post-Depositional Loads

Leachate data from saturated column kinetic tests comprising lithology-specific surface waste rock (VSF, ANDX, P2, S3) were used to assess which parameters have the potential for long term leaching behaviour after deposition in Brucejack Lake. Based on the assessment, As and Sb were identified as parameters showing longer-term release patterns. Post-depositional loads for these parameters were calculated using stabilized column leachate concentration data (*i.e.*., last five analyses, up until August 17, 2017) combined with the surface waste rock schedule (Table 3-6) and assumptions regarding waste rock reactivity. In reality, the loads contributed to Brucejack Lake would be controlled by molecular diffusion; however, waste rock sequencing information is not currently available, therefore the approach used to derive post-depositional As and Sb loads is based on lithology-specific loading rates.

Median and 90th percentile leachate concentration values were used to derive Base Case and Upper Case loading rates. Loading rates (mg/kg/month) for each surface waste rock lithology were multiplied by the respective lithology-specific cumulative waste rock tonnages (Table 3-6) to derive monthly post-depositional loads. Leachate quality from the P2 column was used as a surrogate for the P1 unit when calculating the potential contributions from the P1 waste rock tonnages deposited in Brucejack Lake. It is assumed that any waste rock deposited in the lake will contribute post-depositional loads for approximately one year following placement. It is expected that most of the waste rock dump subaqueous exposed faces will be covered within one year through ongoing deposition of waste rock, thereby burying the underlying layers and limiting post-depositional leaching.

Notes: * Year 1 (Y01) of operations consists of only seven months (June through December of 2017).

3.3.4 Weathered Surface Material

Weathered surface material was excavated from the Mine Site surface in preparation for operations, with the bulk of the excavation occurring in Y-1. A summary of the tracked tonnages of weathered surface material placed in Brucejack Lake is provided in Table 3-10.

Table 3-10:
Tracked Tonnages of Weathered Surface Material Deposited in Brucejack Lake

A geochemical characterization program completed in 2015 indicated there is limited potential for surface materials at the Mine Site to support vegetation, due in part to slow organic matter buildup at this elevation and climate. In addition, the surface material generally has a high PAG potential and elevated metal concentrations (*e.g.*, As levels (21-446 ppm) exceed the CCME guideline of 12 ppm). Overall, the results of the characterization program indicate that the weathered surface material is not suitable for use

in reclamation. As a result, the majority (~111 kt) of the excavated weathered surface material generated to date (particularly the portion with higher rock content) has been deposited in Brucejack Lake. Weathered surface material dominated by soil size fraction particles (<2 mm diameter) (~54 kt) has been stockpiled at the Mine Site for potential reclamation purposes per existing conditions of Permit M-243. Details of the 2015 geochemical characterization program and an overview of the baseline studies are provided in the 2015 Annual Report (Pretivm, 2016a).

SFE data were used to predict the instantaneous loads from Mine Site weathered surface material deposited in Brucejack Lake. Given the relatively fine particle size distribution of the surficial material, all the material is considered reactive (*i.e.*, soluble). Base Case and Upper Case source terms were calculated from the cumulative dataset using median and 90th percentile SFE values, respectively, and the monthly excavation schedule (Table 3-10). The source terms for Base Case and Upper Case are summarized in Table 3-11 and Table 3-12, respectively.

Table 3-11:
Base Case Weathered Surface Material Source Term Loads

3.4 Underground Mine

3.4.1 Overview

Approximately 6.26 Mt of waste rock will be generated through LOM as the underground mine is developed, including waste rock excavated during Construction (September 2015 through May 2017). As described in Sections 1 and 2.2.4, Pretivm is applying for the flexibility to either deposit waste rock sub-aqueously in Brucejack Lake or to place it as backfill in the underground mine, dependent on operational needs. Water quality modelling was completed for two scenarios that represent the extremes for these approaches: Scenario 1, where all waste rock generated in future (5.3 Mt) would be deposited in Brucejack Lake; and Scenario 2, where a maximum amount of waste rock (3.4 Mt) would be backfilled in the underground mine. Tailings discharge to the lake and paste backfill to the underground mine would be balanced according to the waste rock deposition for these scenarios.

Materials backfilled into the underground mine – in addition to wall rock exposures, paste bleed water, and infiltrating groundwater – will contribute a geochemical load to underground mine water. This section describes the geochemical source term for underground mine water and the loads associated with waste rock produced from the underground mine that will be ultimately stored in Brucejack Lake under both modelled scenarios.

3.4.2 Underground Mine Waste Rock

The total mass of waste rock generated from the underground mine during the LOM is estimated to be 6.26 Mt, with 0.96 Mt of waste rock excavated during the Construction phase having been deposited in Brucejack Lake. Waste rock during the Operations phase will be managed through subaqueous deposition in Brucejack Lake and/or backfilling in the underground mine. As described above, Scenario 1 is an endmember scenario whereby all waste rock would be deposited in Brucejack Lake, whereas Scenario 2 maximizes waste rock backfilling into secondary stopes within the underground mine.

Source terms were developed for: 1) underground mine waste rock deposited in Brucejack Lake; and 2) contact water from the underground mine. Underground waste rock terms were derived for both instantaneous and post-depositional loads (as described in Section 3.3.1), along with loads associated with sub-aerial exposure of waste rock while stored on surface before being deposited into Brucejack Lake.

Preliminary ML/ARD characterization of underground mine waste rock (464 pre-2016 samples) showed that the vast majority of samples are PAG (NPR < 2). The confirmatory

sampling program was developed to monitor the geochemistry of rock excavated from the underground mine and assess any potential variation from the initial characterization of the defined geologic model units. Confirmatory sample results to date are generally consistent with prior characterization results, with the majority of samples indicated to be PAG. Given the PAG designation, all waste rock from underground is scheduled to be deposited in Brucejack Lake and/or backfilled in mined out stopes of the underground mine below the post-closure water table. Mine Act Permit M-243 limits subaerial exposure of waste rock to be deposited in Brucejack Lake to a maximum of 2 years. Summaries of the preliminary geochemical assessment and confirmatory sampling results are provided in the Annual Reports (Pretivm, 2016a; 2017).

Lithology-specific underground mine waste rock schedules have been developed for Scenarios 1 and 2. The underground waste rock geologic model units defined for water quality modelling purposes are:

- VSF (volcanically-derived siltstone and sandstone);
- ANDX (latite to andesite fragmental volcanics);
- S3 (cobble to boulder conglomerate with sandstone);
- Office P1 (hornblende, feldspar phyric latite flows);
- Office P2 (plagioclase, K-feldspar, hornblende porphyry); and
- Silicified Cap (silicified heterolithic conglomerate, sandstone and mudstone).

The schedules for underground waste rock placement in Brucejack Lake are presented in Table 3-13 and Table 3-14, for Scenarios 1 and 2 respectively. The underground mine backfill waste rock schedule is presented in Table 3-15 and only applies to Scenario 2. For each scenario, loads were calculated for the instantaneous release, diffusive release and potential leaching due to exposure on the waste rock deposition pad. Loads associated with backfilled waste rock are presented in Section 3.4.3 along with other mine water components.

3.4.2.1 Instantaneous Loads

Lithology-specific SFE data sets combined with waste rock deposition schedules were used to predict the instantaneous loads from underground waste rock deposited in Brucejack Lake, as described in Section 3.3.3.1 for surface waste rock. The revised source terms for instantaneous loads to Brucejack Lake from submerged underground waste rock incorporate all available SFE data and utilize the tracked waste rock tonnages deposited in Brucejack Lake during the Construction phase and year 1 of Operations, as well as the projected waste rock schedules (Scenario 1 (Table 3-13) and Scenario 2 (Table 3-14)) for the increased mine production rate.

Monthly loads are scaled to account for the proportion of waste rock considered to be reactive (*i.e.*., soluble) using the fraction of material that is < 6.4 mm, estimated to be approximately 40% of the total underground waste rock. The proportion of reactive fines assumed for the waste rock is based on particle size distributions completed for representative subsamples from field bin and saturated column tests.

Base Case and Upper Case source terms were calculated from the cumulative dataset using the median (or 75th percentile in some cases to be consistent with observed lake quality)

and 90th percentile lithology-specific SFE values and the scaled monthly waste rock excavation tonnages (Table 3-13 and Table 3-14). Base Case and Upper Case source terms for waste rock submerged in Brucejack Lake using the recorded tonnages for the Construction phase are presented in Table 3-16 and Table 3-17, respectively. The revised source terms for Base Case and Upper Case under the Scenario 1 waste rock schedule are summarized in Table 3-18 and Table 3-19, and the terms predicted for the Scenario 2 waste rock schedule are presented in Table 3-20 and Table 3-21. An additional calibration factor was applied to Sb concentrations to better align with observed Sb concentrations in Brucejack Lake.

Notes: Year 1 of operations consists of only seven months (June through December of 2017).

3.4.2.2 Post-Depositional Loads

Leachate data from saturated column kinetic tests comprising waste rock from the underground mine (VSF, Fragmental and Conglomerate (S3)) were used to assess which parameters have the potential for longer-term leaching behaviour. Based on the assessment, As and Sb were identified as parameters showing longer-term release patterns. These are the only parameters for which a post-depositional load is applied. Post-depositional loads for these parameters are based on stabilized waste rock column leachate concentration data (*i.e.*, last five analyses, up until August 17, 2017) combined with the underground waste rock schedule (Table 3-13 and Table 3-14) and assumptions regarding waste rock reactivity.

Median and 90th percentile leachate concentration values were used to derive Base Case and Upper Case loading rates. Loading rates (mg/kg/month) for each underground waste rock lithology were multiplied by cumulative waste rock tonnages calculated from lithology-specific tonnages presented in Table 3-13 and Table 3-14. Leachate quality from the surface P2 column was used as a surrogate for the underground Office P2 and Office P1 units when calculating the potential contributions from these waste rock tonnages deposited in Brucejack Lake. Leachate quality from the acid generating S3 column was used as a surrogate for the Silicic Cap. It is assumed that any waste rock deposited in the lake will contribute post-depositional loads for approximately one year following placement. After this time, it is assumed that on-going deposition of waste rock from development of the underground mine limit post-depositional leaching.

Base Case and Upper Case As and Sb predictions for post-deposition loads for Scenario 1 and Scenario 2 are summarized in Table 3-22 and Table 3-23, respectively.

The contribution of post-depositional loads is projected to continue throughout the Closure and Post-closure periods. Ultimately, final tailings production and natural sedimentation in Brucejack Lake are assumed to bury the final waste deposits and inhibit further contaminant release.

3.4.2.3 Surface Exposure Loads

Most of the underground waste rock brought to surface will be deposited in Brucejack Lake immediately; however, a portion may be stored at surface for up to two years prior to subaqueous deposition as per *Mines Act* Permit M-243 Condition D.3(c)(v). The exposed surface portion of the waste rock dump (the pad) develops as waste rock is added to the dump and waste rock is pushed into the lake. Subaerially exposed PAG pad materials may be replaced with either NPAG or fresh PAG materials within the two-year time frame, or the surface PAG materials may be excavated and deposited in the main body of the lake, leaving shallow ponded areas within the pad (geotechnical and other conditions apply to these activities).

Accumulated loads associated with exposure of waste rock over a two-year time frame have been incorporated into the updated Brucejack Gold Mine water quality model. Proportional loads from the four major geological model units (representing 96% of waste rock to be excavated from the underground mine; Table 3-13) were determined based on field bins leachate results (as presented in the 2016 Annual Report; Pretivm, 2017) and the estimated maximum volume of waste rock to be subaerially exposed on the waste rock platform at any given time (~180,000 m^3). The total loads accumulated over a two-year time frame, along with the monthly loads for May-October (*i.e.*, the months when leaching would be anticipated), are presented in Table 3-24.

Table 3-24:
Subaerially-exposed Underground Waste Rock Loads

3.4.3 Underground Mine Water

The underground workings of the Brucejack Gold Mine are primarily below the groundwater table and thus dewatering is required for all active phases of mine development. Water in the underground mine is collected and conveyed by a system of sumps and pumps located throughout the working levels, with all water ultimately reporting to a main sump that is pumped to a clarifier before being directed to the WTP.

Individual components of the underground mine workings source term include: blasting residues, groundwater inflow, exposed wall rock, waste rock fill (Scenario 2 only), paste backfill (cemented thickened tailings) and bleed water from paste backfill. Loadings associated with blasting residues are summarized separately in Section 3.8. The following sections describe the development of geochemical source terms for the mine underground during Operations and Post-closure. Loads from paste backfill bleed water contributing to the underground mine water source terms are discussed under Mill Components (Section 3.6).

3.4.3.1 Background Groundwater

The groundwater source term component of the model is based on adit drainage water quality observed during saturated time periods (*i.e.*, when the mine was flooded). Adit drainage represents water from a relatively large drainage area, and thus is considered to provide a more representative estimate of typical background groundwater than any individual groundwater well. Therefore, water quality sample data from the Brucejack adit during time periods when the mine workings were saturated were used to estimate the geochemical load carried in background groundwater. Median and maximum concentrations observed in adit drainage from 2009 to October 2011 (*i.e.*, when the mine workings were saturated) were used for the Base Case and Upper Case source terms, respectively (Table 3-25). This term is unchanged from the original MA-EMA Permits Application (Pretivm, 2015).

Table 3-25:

3.4.3.2 Wall Rock

The exposed wall rock areas will increase as the mine develops and contribute increasing geochemical loads to the underground system. The wall rock exposure schedule is presented in Table 3-26.

Source terms for exposed underground wall rock are based on the lithology-specific humidity cell data (based on units described in Section 3.4.2) and wall rock conversion factors calibrated from site monitoring data. The wall rock source term is calculated by multiplying humidity cell loading rates (units of mg/kg/wk) by wall rock conversion factors (units of kg/m^2) which produce area normalized wall rock loading rates (units of $mg/m^2/wk$). Details of the approach are outlined in the MA-EMA Permits Application

(Pretivm, 2015). Updates to source term inputs used since the 2016 Annual Report (Pretivm, 2017) and MA-EMA Permits Application include:

- Classification of humidity cell weathering state (neutral/acidic);
- Additional humidity cell test results;
- Wall rock conversion factors updated with recent monitoring data and wall rock exposure estimates; and
- Humidity cell statistics used in wall rock conversion factor calibration.

The classification of humidity cell weathering state has been updated to reflect the evolving pH conditions in humidity cell tests. Humidity cells HC21 (S3) and HC31 (VSF) became persistently acidic (pH < 6) after 110 and 125 cycles, respectively. Data collected from earlier dates is still incorporated into the 'neutral' pH loading rates for the respective lithologies, while data collected after the cells became persistently acidic is incorporated into the 'acidic' loading rate. The updated humidity cell classification used to represent different rock units and acidic waste rock is shown in Table 3-27.

The humidity cell tests shown in Table 3-27 are ongoing, and additional results have been incorporated into statistics on loading rates used to calculate source terms. This source term update incorporates data available up until August 22, 2017. The 75th percentile loading rates were used to derive Base Case loads, while the 90th percentile values were used to derive the Upper Case loads (Table 3-28). The 75th percentile was used as opposed to the median loading rates to be consistent with wall rock conversion factor calibration, which used 75th percentile values, as described below. The final humidity cell loading rates calculated as the median of the last 5 cycles were used to calculate the Post-closure loading rate. This loading rate is applied in both Base Case and Upper Case scenarios (Table 3-28).

Table 3-26: Cumulative Wall Rock Exposures Over Mine Life

The calibration of wall rock conversion factors has been updated with recent mine dewatering and water quality data. The wall rock conversion factor is a calibrated scaling factor, which relates wall rock normalized loading rates from the mine underground to humidity cell loading rates. The time period used in the original MA-EMA Permits Application was January 2013 to December 2013. This time period was selected to account for seasonal variations in flow and loading rates over a full calendar year, and because active mining was taking place during this time period. The calibration time period used in the updated model is based on data collected from January 2015 to December 2016. This time period incorporates active mining and seasonal variations over a two-year time period, and has the advantage of increased water quality monitoring frequency. Data after December 2016 are not incorporated, as significant re-circulation of surface water to the underground mine began in 2017 (10 to 11759 m^3/month from January 2017 to August 2017). Figures comparing measured and modelled concentrations for sulfate, D-As and D-Sb are shown in Figure 3-1, Figure 3-2 and Figure 3-3, respectively.

Figure 3-1: Time series plot showing modelled and measured sulfate concentrations over the calibration time period (January 2015 to December 2016).

Figure 3-2: Time series plot showing modelled and measured D-As concentrations over the calibration time period (January 2015 to December 2016).

Figure 3-3: Time series plot showing modelled and measured D-Sb concentrations over the calibration time period (January 2015 to December 2016).

In the original MA-EMA Permits Application, the first 5 cycles of humidity cells were used to calculate wall rock conversion factors. Since this time, the geochemistry of underground mine water has evolved, and the 75th percentile loading rates are considered to better represent loading rates.

The updated wall rock conversion factors calculated over the calibration time period are provided in Table 3-29. The revised wall rock source terms are presented in Table 3-30 and Table 3-31.

3.4.3.3 Waste Rock Backfill

Waste rock backfill will be placed in the mine underground in Scenario 2. Scenario 1 assumes that all waste rock will be placed in Brucejack Lake. The Scenario 2 waste rock backfill schedule is presented in Table 3-15.

Waste rock fill source terms are based on lithology-specific humidity cell data scaled to reflect field conditions following the approach outlined in the MA-EMA Permits Application (Pretivm, 2015). The updates to the paste backfill source term since the 2016 Annual Report include:

- Re-classification of humidity cell weathering state (neutral/acidic); and
- Additional humidity cell test results.

The same humidity cell groupings that were used in calculating the wall rock source term were applied to the waste rock backfill source term (Table 3-27). Median and 90th percentile loading rates were used to estimate the Base Case and Upper Case rock fill source terms, respectively (Table 3-28). The scaled waste rock backfill loading rates used to calculate the updated underground mine water source term are provided in Table 3-32.

Upon mine closure, backfilled waste rock will be submerged below the final water table to mitigate the long-term potential for ARD development, as per *Mines Act* Permit M-243. As such, no unsaturated waste rock backfill term has been developed for Post-closure.

Table 3-32:

3.4.3.4 Paste Backfill Operations

Paste backfill will be placed in underground voids for ground support. The schedule for placement of paste backfill to the underground mine and the tonnage that will remain above the final water table in Post-closure is provided in Table 3-33. The source term for paste backfill is derived by scaling humidity cell loading rates to field conditions, as described in MA-EMA Permits Application. The paste backfill source term has been updated with new kinetic test data since the 2016 Annual Report.

The only humidity cell used to represent paste backfill is T12; updates to the source term include additional results acquired through August 2017. The median and 90th percentile loading rates from this humidity cell were used to calculate Base Case and Upper Case source terms operations source terms, respectively (Table 3-34). The loading rate from the final 5 cycles of T12 were used to estimate both Base Case and Upper Case Post-closure paste tailings source terms. These loading rates were scaled as described in MA-EMA Permits Application, resulting in the paste backfill source terms shown in Table 3-32.

3.4.3.5 Paste Backfill Closure

Upon mine closure the water table will rebound and saturate much of the underground mine workings. This rebound in the water table will submerge the paste tailings, wall rock exposures and rock fill. Saturated conditions will inhibit acid generation and metal leaching associated with sulfide mineral oxidation; however, some metal leaching may continue from dissolution of oxide minerals. The paste backfill source term has been updated with new kinetic test data since the 2016 Annual Report (Pretivm, 2017).

The flooded mine workings source term was developed using the approach described in the MA-EMA Permits Application (Pretivm, 2015). This approach estimates the concentration of waste rock backfill porewater, tailings porewater, and wall rock contact groundwater to calculate the flooded mine workings source term. It is assumed that groundwater infiltrating through saturated mine workings will interact with all three saturated mine components, and as a conservative assumption, the saturated mine workings source term is the highest concentration associated with any one mine component.

Data used to represent the mine components include: saturated columns 1 and 2 for backfilled waste rock; saturated columns 2 and 3 for paste backfill; and, mine portal water quality from time periods when mine workings were flooded and passively discharging (to estimate background water quality). Revised saturated column results were used to re-calculate the flooded mine source terms for the rockfill and paste backfill components by incorporating saturated column results up until August 2017. The background groundwater component has not been updated. The updated 90th percentile values and final saturated column concentrations used in the Base Case and Upper Case Post-closure scenario are provided in Table 3-36. The resulting flooded mine source term is presented in Table 3-37.

Table 3-36:
Concentrations Applied to Different Components of Underground Mine Workings to Predict Saturated Mine Workings Source Terms

3.4.3.6 Underground Mine Water Source Term

Potentially acid generating wall rock and backfill (Scenario 2 only) will be unsaturated in the mine workings during Operations. Upon mine closure, the water table will rebound, submerging all backfilled PAG waste rock. However, some PAG wall rock will remain above the final water table in Post-closure.

During mine operations, gradual acidification of the wall rock is incorporated into source term predictions. In Post-closure, it is assumed that all PAG exposures are acid generating.

The rate at which wall rock from the different lithologies becomes acid generating is described in Appendix E.4 of the 2015 ME-EMA Permits Application. No updates have been made to assumptions regarding acid generation in the underground mine workings.

Upscaling humidity cell loading rates often results in unrealistic concentrations, particularly when large numbers of detection limit values are incorporated into upscaling calculations. In order to ensure that the predicted concentrations are realistic, a number of final concentration adjustments were made. These concentration adjustments have been applied to elements which were generally below detection limits in field data and laboratory testwork, and for elements which field evidence indicates are pH controlled. The final adjustments described in the MA-EMA Permits Application are still considered valid except that the time period of adit drainage data used to set Zn, Cd, Cu and Ni solubility controls has been updated.

The solubility of metal cations, such as Zn, Cd, Cu and Ni, is strongly tied to pH. An inverse relationship with pH is evident in adit drainage, as described MA-EMA Permits Application. Specifically, Zn and Cd concentrations decline in adit drainage when mine workings are dewatered which is attributed to an increase in pH that occurs over this transition. In the Base Case it is assumed that the current pH observed in adit drainage will be maintained in the future. The solubility of these parameters was originally set to the maximum concentration observed from beginning of mine dewatering in 2011 to early 2014. The mine workings were not continuously dewatered during this time period, and a peak in concentrations was observed when dewatering was suspended. The solubility caps have been updated to only consider data collected since the beginning of Construction (June 2015 to September 2017). The original and updated solubility controls for these parameters are shown in Table 3-38. No final adjustment in concentrations has been applied to the Upper Case scenarios for these parameters.

Table 3-38:
Solubility Controls Applied to MA-EMA Permits Application and Updated Solubility Caps Applied to Current 2018 Application for Cd, Cu, Ni and Zn

Parameter	Units	MA-EMA Permits Application	2017 Application
		Base Case	Base Case
Cd	mg/L	0.00044	0.0001
Cu	mg/L	0.0057	0.0013
Ni	mg/L	0.0017	0.0089
Zn	mg/L	0.073	0.0197

The end of Operations and Post-closure source terms for underground mine water are provided in Table 3-39. This source term combines the loadings described in Section 3.4.3, in addition to paste bleed water which is described in Section 3.6. Note that the underground source term is calculated on an annual basis, taking into account the schedules for the various mine components and the volume of groundwater inflow.

In general, the updated Operations source term concentrations are higher than predictions from the 2015 MA-EMA Permits Application for a number of parameters (*e.g.*, As, Sb and sulfate), while Post-closure concentrations are relatively unchanged. This is in large part related to changes in predicted dewatering rates. The mean dewatering rates decreased from 108,800 m^3/month in the 2015 MA-EMA Permits Application model to 33,900 m^3/month in the current model predictions.

3.5 Operations Water Treatment Plant

3.5.1 Overview

The Operations WTP receives and treats underground mine water from mine dewatering, surface contact water and WTP effluent collected in the CWP, and recycled process water from the Mill. The WTP is designed to chemically precipitate targeted dissolved metals and remove resultant chemical precipitates and influent total suspended solids (TSS), at flow rates between 1,400 m^3/day and 10,000 m^3/day. The water treatment design, metals and solids removal process, and effluent design criteria are described in the 2015 MA-EMA Permits Application (Pretivm, 2015). Key components of the WTP treatment process include a pre-treatment Clarifier (for coarse TSS removal), Primary Metal Precipitation Stage (for sulfide metal precipitation and TSS removal), Secondary Metal Precipitation Stage (for hydroxide metal precipitation and TSS removal) and Final Metal Polishing by filtration (for small particulate TSS removal). The WTP will operate through LOM and into the Closure phase for as long as necessary.

The WTP generates a solid waste product (sludge) that requires management and disposal. The mass of the sludge produced depends on the TSS content of the influent, the chemical composition of the influent, the flow rate, and the nature of the solid particles. The estimates of the total amount of sludge to be produced during the Operations phase is predicted to be approximately 40 kt, with sludge generation estimated at 7 tpd. The total amount of sludge generated is estimated to represent approximately 1 to 2% of the total tailings generated on-site. Sludge generated from the WTP is currently being co-deposited with thickened tailings into Brucejack Lake.

As summarized in Section 2.2.2, a portion of WTP effluent supplies water to the Mill and a portion is discharged to Brucejack Lake via the discharge line at a depth of approximately 36 m. Source terms were developed for: 1) WTP effluent; and 2) WTP sludge co-deposited with tailings in Brucejack Lake. The approach for deriving the WTP effluent source term is described in the following section, whereas the geochemical source term applied for sludge is described in Section 3.6.5.

3.5.2 WTP Influent

The Operations WTP influent quality was derived from influent flows as prescribed by the Brucejack Gold Mine water balance and source terms developed for the contributing sources: underground mine water (Section 3.4.3), Mine Site Runoff (Section 3.3.2) and process water (Section 3.6). The modelled WTP influent parameter concentrations for both mine scenarios as compared to corresponding values in the 2015 MA-EMA Permits Application are presented in Table 3-40. The maximum predicted influent concentrations of dissolved metals treated by the WTP (Ag, Al, As, Cd, Co, Cu, Fe, Mn, P, Pb, and Zn) are generally within 3 times the 2015 MA-EMA Permits Application predicted values, and all are within an order of magnitude of the previously modelled values.

Table 3-40:
Maximum Operations Water Treatment Plant (WTP) Influent Predictions as Compared to Predictions from the MA-EMA Permits Application (Pretivm, 2015)

Notes:
The modelled metals are dissolved values; TSS was not included in the water quality model.
The concentrations provided are maximum values predicted for the Operations Phase.
Grey shading indicates the modelled value is 3-fold or more above the corresponding value in the 2015 MA-EMA Permits Application.

3.5.3 WTP Effluent

Modelled Operations WTP effluent quality is based on predicted influent quality (Table 3-40) and assumptions regarding the efficacy of the treatment process, following the same general approach as outlined in the 2015 MA-EMA Permits Application (Pretivm, 2015). The concentration of parameters targeted for treatment are capped at Design Criteria concentrations (Table 3-41) that were developed from bench scale experiments conducted by Veolia (Appendices 7-V and 7-W of Pretivm, 2015); these values were adopted as WTP effluent discharge guidelines in the Brucejack Gold Mine Effluent Permit (PE-107835). Sulfate (SO_4) is not treated, rather it is added to the effluent from the reagents that are used for treatment; therefore, the water quality model conservatively increases the Operations WTP influent sulfate concentration by the maximum Design Criteria incremental amount (400 mg/L).

The Design Criteria effluent concentrations applied to the MA-EMA Permits Application model are considered to be valid for the increased mill production water quality model. The ability of the WTP to treat maximum predicted influent concentrations of targeted parameters (TSS, Ag, Al, As, Cd, Co, Cu, Fe, Mn, P, Pb, and Zn) to effluent design criteria is supported by bench scale testing conducted in 2015 (Table 3-41), the performance of the Construction WTP from May 2015 through June 2017, and the performance of the Operations WTP since commissioning in July 2017. The Construction WTP treatment process was similar to the secondary metal precipitation and final filtration stages of the Operations WTP and monitoring data indicate effluent concentrations were lower than the Design Criteria for the duration of the Construction WTP operational period (performance data is summarized in the 2015 and 2016 Annual Reports (Pretivm 2016a; 2017)). Similarly, monitoring data indicate that the Operations WTP has consistently produced effluent concentrations that are lower than Design Criteria since it was commissioned in 2017.

The influent water quality observed to date is well below modelled maximum concentrations for most targeted dissolved metals and thus the Operations WTP treatment efficacy at modelled concentrations is evaluated from bench scale testing conducted in 2015. Three separate studies were conducted. The first two studies were completed prior to, and included with, the MA-EMA Permits Application (Pretivm, 2015); the third investigation was completed July 25, 2015 and is provided in Appendix 1, *Operation Water Treatment Plant Additional Metals Removal Bench Tests* (*i.e.*, bench test #3). The MA-EMA Permits Application Operations WTP influent Upper Case maximum values for dissolved metals were used as target values for the preparation of synthetic influent solutions for bench testing.

Table 3-41:
Summary of Maximum Operations Water Treatment Plant (WTP) Influent and Effluent Predictions Compared to Bench Test Results and Effluent Design Criteria for Targeted Parameters

Parameter	Units	Influent			Effluent

Notes:
Metals are dissolved values; TSS was not included in the water quality model.
Design Criteria were developed for total metal parameters and confirmed by bench scale testing. Metal precipitation processes are relevant for dissolved metal removal and were evaluated based on the dissolved metal bench scale test results presented in the table.
The modelled influent and effluent concentrations are the maximum of the Scenario 1 and Scenario 2 values predicted for the Operations Phase.
Bench test results are from bench test Report #3 (Appendix 1), except Al and P which are from bench test Report #2. The Ag and Cu results are from the primary treatment stage test results.
SO_4 is not treated by the WTP. Treatment reagents are modelled to contribute the maximum amount indicated to influent concentrations.
Grey shading indicates the modelled maximum influent value is 3-fold or more above the corresponding bench test influent concentration.

Due to the complex composition of the synthetic influent, certain parameters (*e.g.*, Ag, As and Fe) were subject to continuous precipitation reactions and were therefore difficult to maintain at measurable or elevated dissolved concentrations even through repeated pH adjustments and supplementary additions of soluble metal salts. This indirectly suggests that these parameters will be effectively treated within the WTP. The removal of Ag was only evaluated in the precipitated form (measured as total Ag); however, this was due to the difficulty in maintaining Ag in a dissolved form (measured as dissolved Ag) during bench scale testing and indirectly indicates Ag insolubility at concentrations below the design criteria (0.0001 mg/L). Similarly, dissolved As was unstable in the synthetic influent and rapidly converted to particle bound As that was measured as a constituent of the total As parameter. The bench test data indicate dissolved As is effectively removed to well below design criteria effluent concentrations (0.01 mg/L). Although Pb was not evaluated at the Upper Case maximum concentration (0.079 mg/L for dissolved Pb) it was

effectively removed to well below the design criteria concentration (0.005 mg/L), indicating the effluent design criteria are achievable for the maximum modelled dissolved Pb concentrations.

Overall, the target parameter influent concentrations achieved for bench scale testing were higher than, or similar to, the modelled Base Case and Upper Case concentrations for Operations WTP influent, and therefore strongly support that the Operations WTP process will achieve Design Criteria effluent quality, or better, for maximum modelled influent concentrations.

3.6 Mill

3.6.1 Overview

The Brucejack Gold Mine mill processes ore using conventional bulk sulfide flotation and gravity concentration to recover gold and silver. The mill produces a gold-silver bearing flotation concentrate which is shipped off-site for further processing. The gravity concentrate is refined on site to produce gold-silver doré ingots.

The revised mine production schedule will result in an estimated total of 18.4 Mt of ore being processed through the mill over LOM, which will generate approximately 17.4 Mt of thickened tailings (Table 3-42). Tailings are managed through subaqueous deposition in Brucejack Lake and through placement in the underground mine as cemented paste backfill.

Schedules for the two deposition scenarios are summarized in Table 3-42. Scenario 1 assumes that 50% of the tailings (8.7 Mt going forward) will be deposited in Brucejack Lake and 50% will be placed as cemented paste backfill. Scenario 2 has a significantly higher proportion of tailings being placed in Brucejack Lake (68%; 11.9 Mt) to accommodate the placement of waste rock backfill in the underground mine.

The mill components of the GoldSim water quality model have been reconfigured as compared to the original MA-EMA Permits Application based on revisions to flows within the mill circuit. The model has also been updated with revised or new source terms developed for inputs to the mill. The inputs include:

- WTP effluent (described in Section 3.5.3);
- WTP sludge slurry, comprised of approximately 2.5% solids. The WTP sludge slurry is combined with the flotation tailings which are then thickened prior to discharge. Authorization for co-deposition of sludge with tailings was issued via amendment of *Mines Act* Permit M-243 and Effluent Permit 107835 in March/April, 2017 and this term is now incorporated into the water quality model,

where the WTP sludge slurry water is assumed to have the same composition as WTP effluent;

- Reclaim water from Brucejack Lake: make-up water supplied to the mill;
- Recycled process water: water from ore processing that is treated by the WTP and circulated back into the mill process as feed water. This is a new model component and the model allows for concentrations of untreated parameters to build up over time;
- Ore moisture: water that is on the surface of ore processed through the mill;
- Slime water: water associated with the fines that will processed through the mill; and
- Tailings loads: loads added from processed ore.

The tracked outputs include the tailings slurry discharged to Brucejack Lake, the process water that is recycled to the mill via the WTP and paste backfill discharged to the underground mine. The following sections describe the source terms developed for the various mill components.

Table 3-42:
Scheduled Ore and Predicted Tailings Tonnages to Brucejack Lake and to the Underground Mine as Paste Backfill

Phase	Year	Scheduled Ore for Processing	Total Tailings Generated	Scenario 1		Scenario 2	
				Tailings to Brucejack Lake	Tailings to Paste Backfill	Tailings to Brucejack Lake	Tailings to Paste Backfill

3.6.2 Reclaim Water

The Mill water supply is supplemented by reclaim water pumped from the weir located at the outlet of Brucejack Lake (BJ 3.10) as authorized under Conditional Water License C133725. Pretivm is applying to replace this water licensing for the proposed production increase, as the updated water balance flow model (BGC, 2018) predicts a water shortfall during the low flow months of the year (*i.e.*, based on the current water license conditions). The water quality of reclaim water in the model was set to Brucejack Lake values predicted for BJ 3.10 by the water quality model.

3.6.3 Slime Water

Slimes are settled fines generated during mine operations as a result of mucking, blasting and other underground development activities. Slimes are anticipated to have relatively high gold and silver concentrations and are pumped to the mill from the underflow stream of the WTP's clarifier. The slimes, estimated to consist of approximately 30% solids, are processed through a dedicated flotation circuit before reporting to the head of the cleaner flotation circuit for the ore stream. Tailings generated from slimes are estimated to represent approximately 1 to 2% of the total tailings generated from ore processing. The geochemical characteristics of slimes have been described in the MA-EMA Permits Application (Pretivm, 2015) and the Annual Reports (Pretivm, 2016a; 2017). In general, slimes are PAG with elevated concentrations of Ag, As, Cd, Pb, S, Sb, Se, and Tl.

Water quality associated with slime-related flows to the mill is assumed in the water quality model to be equivalent to the underground mine water quality (Section 3.4.3).

3.6.4 Ore Moisture

During ore excavation, mine water from the underground workings becomes entrained in the ore muck pile. The water balance model assigns a flow to the water that is associated with ore to be processed through the mill, termed ore moisture. The water quality of ore moisture is assumed in the water quality model to be equivalent to the underground mine water quality (Section 3.4.3).

3.6.5 Tailings and WTP Sludge Loads

The physical grinding and chemical processing of ore results in the release of chemical loads into the mill's process water. These instantaneous loads are added to loads already present in process water from the various contributing sources (*i.e.*, WTP effluent, WTP sludge slurry water, reclaim water, ore moisture and slime water). The combined mill loads are discharged to Brucejack Lake with the tailings slurry and to the underground mine with the paste backfill. The tailings discharged to Brucejack Lake are co-deposited with WTP

sludge, and following deposition, loads may be released to Brucejack Lake through diffusive processes.

The following section describes the approach for deriving: 1) instantaneous tailings loads introduced to the mill; and 2) diffusive loads added to Brucejack Lake from tailings and WTP sludge.

3.6.5.1 Instantaneous Tailings Loads to Mill

The approach for deriving tailings loads has been updated since the 2015 MA-EMA Permits Application. Previously, the loads associated with tailings discharged to Brucejack Lake were calculated based on the supernatant water quality from laboratory-based metallurgical tests carried out on the 2013 10,000 tonne Bulk Sample. The current approach for estimating tailings loads applied in the updated water quality model is based on operational monitoring data collected in July 2017 for thickened tailings (supernatant water quality, water content and mass) and mill feed water (flow and water quality). The GoldSim model has been updated to account for recycling of mill process water and tracks the changing chemistry of all flow-related mill inputs. The loads released during ore processing (*i.e.,* the tailings loads) will likely vary with the changing ore composition, but for the purposes of modelling, the loads are assumed to be constant for a given tonnage of ore processed through the mill. The model tracks all inputs and calculates the composition of the tailings slurry water that is discharged to Brucejack Lake.

Tailings loads were calculated as the difference between the total monthly loads (input) to the mill (as feedwater) and the total monthly loads discharged (output) from the mill. Monitoring data from July 2017 were used for development of the tailings load source term since detailed flow and water quality records were available for mill inputs and outputs at the time of reporting. Furthermore, the feed water to the mill during the July 2017 sampling period was composed exclusively of Brucejack Lake water, which simplified the calculations. In subsequent months, the feed water was composed of a combination of WTP effluent, Brucejack Lake water and recycled process water.

The total mill input loads for July 2017 were calculated from measured Brucejack Lake water quality and mill input flow data, and the discharge loads were calculated from the thickened tailings supernatant water quality, the measured solids content (63 wt.%) and the mass of tailings discharged to the lake during this time period (76,924 tonnes; Table 3-43). The loads added to the mill from tailings are calculated from the difference between mill inputs and outputs, where Base Case and Upper Case loads were derived from 75th percentile and 90th percentile thickened tailings supernatant quality results, respectively. The predicted Base Case and Upper Case instantaneous tailings loads added to the mill,

presented in Table 3-44 and Table 3-45, were calculated from the per tonne loadings and the annual tailings schedule (Table 3-42).

Table 3-43:

3.6.5.2 Diffusive Loads from Tailings and WTP Sludge to Brucejack Lake

Diffusion-related loads from co-deposited tailings and WTP sludge to Brucejack Lake were estimated based on saturated column results and assumptions regarding diffusional transport. A brief overview of how the diffusive flux values were calculated is presented below. Additional discussion related to diffusional transport processes, contaminant behaviour and potential water quality impacts with respect to the co-deposition of sludge with tailings in Brucejack Lake is provided in a report (*Brucejack Gold Mine: Assessment of Long-Term Sludge Stability for In-Lake and Underground Deposition* (Lorax, 2016a)) that was submitted for the *Mines Act* Permit M-243 and Effluent Permit 107835 amendment applications approved in March/April 2017.

The rate of diffusional transport in sediment porewaters is a function of the concentration gradient, temperature, sediment grain size, porosity and solute size, and can be described by Fick's First Law (Eqn. 1):

$$Jz = \frac{Doj}{F} \phi \frac{dc}{dz}$$

where J_z is the diffusive flux; D^o_j = *in situ* diffusion coefficient; F = formation factor; ϕ = porosity; and dc/dz = the concentration gradient. Formation factor is a measure of tortuosity, and takes into account the convoluted path ions must follow to circumvent sediment particles (Li and Gregory, 1974). Diffusion coefficients are temperature dependent, with values increasing commensurately with temperature.

To simplify the calculations, a common diffusion coefficient (5×10^{-6} cm^2/s) was assumed for all parameters, as per values presented in Li and Gregory (1974), normalized to 5ºC. Flux calculations also assumed a formation factor of 2 (Ullman and Aller, 1982) and an estimated porosity of 0.7 for silt-sized materials. Leachate data from saturated column test TCol 14 comprising tailings and WTP sludge were used to calculate the concentration gradient (dc/dz).

Calculation of the concentration gradient (dc/dz) included the following assumptions:

- Concentration endmembers in sludge-bearing porewater were set equal to the maximum values measured in saturated column TCol 14;
- Concentration endmembers in the lake bottom water were set equal to mean annual baseline conditions measured at station BJ 3.10;
- The sediment depth over which diffusion is assumed to apply is 3 cm; and

- Flux calculations do not account for sorption processes within the uppermost oxic sediment layers. This imparts a considerable degree of conservatism since a significant fraction of the upward diffusing Mn and Fe can be expected to re-precipitate as their respective oxide phases in the near-surface sediments and remove trace elements that show strong binding affinities for Fe and Mn oxide surfaces (*e.g.*, As, Cd, Co, Cu, Pb, Ni and Zn).

Derived fluxes (J_z) were used to calculate the annual diffusive load for each parameter to the lake water column by multiplying the diffusive flux (µg/cm^2/year) for each parameter by the estimated annual tailings surface area (m^2). The annual tailings surface areas are assumed to grow at a steady rate up to a final estimated tailings surface area of 382,250 m^2. The annual diffusion-related loads contributing to Brucejack Lake from co-deposited tailings and WTP sludge are presented in Table 3-46.

Notes: * Year 1 (Y01) of operations consists of only seven months (June through December of 2017).

3.6.6 Paste Backfill Bleed Water

Porewater contained in paste backfill that is not consumed during the cement curing process will be released as bleed water. The bleed water source term applied in the 2015 MA-EMA Permits Application was assumed to have a constant concentration and was based on the initial flushing results from paste backfill humidity cell HC 37 (median and maximum of the first 5 results for Base Case and Upper Case, respectively). The approach for derivation of the paste backfill bleed water term has been revised. Specifically, bleed water quality was assumed to be equivalent to the predicted mill process water composition for all parameters except Cr, which is dominantly introduced from the cement during paste generation.

The predicted mill process water composition was calculated in GoldSim considering the flows and concentrations of components introduced to the mill (*i.e.*., WTP effluent, reclaim water, ore moisture and slime water), along with the loads added from the processed ore (the instantaneous tailings loads). Base Case and Upper Case process water predictions are based on the Base Case and Upper Case terms for the components introduced to the mill.

Chromium concentrations in paste backfill bleed water were calculated following a similar approach to that described in the 2015 MA-EMA Permits Application, whereby values were based on the initial flushing results of a paste backfill humidity cell (T12). Humidity cell T12 was initiated in March 2016 and comprises thickened tailings generated from metallurgical testwork carried out on the Bulk Sample mixed with 3.9% cement binder (provided by the Brucejack Gold Mine cement supplier). The new data are considered to be more representative of bleed water than the original paste backfill humidity cell (HC 37) which used cement sourced from a different supplier with higher Cr concentrations. Base Case and Upper Case bleed water Cr concentrations were based on the median (0.040 mg/L) and the maximum (0.10 mg/L) concentrations observed in the first 3 cycles of humidity cell T12. The full set of results for humidity cell T12, along with all other humidity cells results, are presented on an annual basis in the Annual Reports.

3.7 Sewage Treatment Plant

3.7.1 Overview

STP effluent is discharged to Brucejack Lake at a depth of 36 m and contains elevated nutrient levels compared to background. An STP source term was therefore included in the water quality model to account for the potential effect of these nutrient contributions reporting to Brucejack Lake.

The STP design is unchanged from that described in the MA-EMA Permits Application (Pretivm, 2015), with one Filterboxx STP unit with a rated treatment capacity of 75 m^3/day. Two units are currently in place at the camp resulting in a total treatment capacity of 150 m^3/day. STP effluent is monitored on a monthly basis and performance is reported on an annual basis in the Annual Reports (Pretivm, 2016a; 2017).

3.7.2 STP Effluent

For the STP source term, nutrient concentrations (total P, ammonia, nitrite, and nitrate) as defined by the Filterboxx plant vendor and Municipal Wastewater Regulations were employed. For all other parameters (total and dissolved metals, physical parameters, anions), Smart Quarter background terms derived from the Brucejack Lake outlet (BJ 3.10) dataset were used (Section 3.1). Source terms for nutrient concentrations in STP discharge are summarized in Table 3-47. The model incorporates flows for 2 Filterboxx STP units (=150 m^3/day) throughout Operations.

Table 3-47:
Sewage Treatment Plant Discharge Source Terms for Nutrients in Operations Phase

Parameter	Concentration (mg/L)
Total P	2.8
Ammonia (as N)	122
Nitrate (as N)	20
Nitrite (as N)	1.0

3.8 Nitrogen Source Terms

3.8.1 Overview

Blasting residues originating from the use of explosives represent the dominant source of nitrogen (N) species (ammonia, nitrite and nitrate) in Brucejack Lake. Therefore, the N source terms are finite and distinct from the geochemical source terms arising from rock minerals. The explosives used at Brucejack Gold Mine contain approximately 25% N in the form of ammonia and nitrate; nitrite is created as a by-product of the explosion reaction and through the oxidation of ammonia in mine drainages (Pommen, 1983). The N source terms provided here rely on the implementation of best management practices for explosives handling and blasting as described in the Nitrogen Management Plan (Pretivm, 2016b).

Explosives-related nitrogen species are currently introduced to Brucejack Lake from WTP effluent, waste rock deposition in Brucejack Lake, tailings slurry discharge, NPAG Quarry rock contact water, and Mine Site surface runoff. Nitrogen source terms arising from

background inputs and STP effluent are described in Section 3.1 and Section 3.7, respectively, and are not discussed further in this section.

Nitrogen source terms have been updated from those described in the 2015 MA-EMA Permits Application (Pretivm, 2015) and the subsequent update to the water quality model (Lorax, 2016b), due to availability of additional site-specific monitoring data and mining records. Nitrogen species are water-soluble, and therefore source terms were modelled as instantaneous loads to contact water. The updated methods used to derive water quality model inputs for ammonia, nitrite and nitrate are summarized in the sections below, and described in detail in Appendix 2.

The explosives quantities used per tonne of blasted rock for surface blasting, underground development blasting, and underground production (ore) blasting were assumed to be 0.3 kg/t, 1.54 kg/t, and 0.8 kg/t, respectively, for LOM.

3.8.2 Nitrogen Speciation

The relative distributions of ammonia, nitrite and nitrate used in the 2015 MA-EMA Permits Application (Pretivm, 2015) were based on median value ratios observed in mine water during mine exploration (Table 3-48). Ammonia, nitrite and nitrate were assumed to behave conservatively in Brucejack Lake, therefore mine water distributions were applied to source terms and at the lake outlet (BJ 3.10). During the Construction phase the N species distributions in mine water were distinct from previous observations, and distributions at the lake outlet (BJ 3.10) were found to be enriched in nitrate and depleted of ammonia and nitrite, compared to mine water. Therefore, the N species distributions were revised in the 2016 water quality model update report (Lorax, 2016b), based on observations during mine construction, and set to ratios approximating median values observed in mine water (for N source terms) and Brucejack Lake outlet (for BJ 3.10 discharge).

Table 3-48:
Nitrogen (N) Species Relative Distributions for Source Terms and Brucejack Lake Discharge (BJ 3.10), Applied in the 2015 MA-EMA Permits Application, the 2016 Water Quality Model Update and the Current (2018) Water Quality Model

Model Term	Relative Distribution of N Species (% as N)		
	Ammonia	Nitrite	Nitrate
All N source terms and lake outlet (2015)	14.8 %	4.2 %	81 %
All N source terms (2016, 2018)	28.8 %	5.2 %	66 %
Brucejack Lake outlet (BJ 3.10) (2016)	4.0 %	2.0 %	94 %
Brucejack Lake outlet (BJ 3.10) (2018)	32.2 %	2.3 %	99.7 %

The enrichment of nitrate at the lake outlet as compared to lake inputs is inferred to reflect ammonia and nitrite oxidation (nitrification) in the lake water column. Nitrification is a microbially-mediated process that converts ammonia to nitrite and nitrite to nitrate. Microbially-mediated nitrification processes occur naturally in cold water lakes and can control the distribution of nitrogen species in the water column (Sterner, 2007), typically promoting an increase in the proportion of N in the form of nitrate. Nitrification rates in these environments are affected by temperature, nutrient levels, substrate and other environmental factors (Dvir & Neori, 1999; Kaplan *et al.*, 2000; Gerardi, 2002; Ward *et al.*, 2011; Bristow *et al.*, 2015) which may cause variations of the relative proportions of ammonia, nitrite and nitrate in the water column. Temporary decoupling of the rates of oxidation of N species by microbial communities can also occur, leading to temporary accumulation of ammonia or nitrite. The microbially-mediated oxidation of ammonia to nitrite is considered to be the rate-limiting step for overall nitrification (Ginestet *et al.*,1998).

The current (2018) N distributions presented in Table 3-48 were applied to the water quality model for source term N loads. The 2016 distributions listed in Table 3-48 approximate the median proportional distributions observed in mine water from January 2016 through February 4, 2018; therefore, the 2016 distributions were carried forward for the current (2018) modelling of N loads for all source terms. The N species distributions modelled for the outlet of Brucejack Lake (BJ 3.10) were revised to capture endpoints for low and high nitrification rates in the lake, where a low nitrification rate would yield ammonia at a ratio similar to that observed in mine water, whereas nitrate would be enriched relative to mine water at elevated nitrification rates.

The maximum ratios of N species in the combined mine water and BJ 3.10 monitoring data (January 2016 through January 2018) were used to derive a low nitrification endpoint (ammonia equal to 32.2% of N reporting to BJ 3.10), and high nitrification endpoint (nitrate equal to 99.7 % of N reporting to BJ 3.10). The Brucejack Lake monitoring data indicate that the proportion of nitrite remains low for both endpoints; therefore, the maximum ratio observed at BJ 3.10 (2.3 % of N reporting to BJ 3.10) was used for nitrite. Although the revised distributions sum to 134.6% of the total N predicted to report to BJ 3.10, this approach is considered appropriate as it addresses the uncertainty associated with nitrification processes. The N species distributions will continue to be monitored throughout LOM to validate and refine the modelling assumptions.

3.8.3 Mine Site

3.8.3.1 Overview

As indicated in Section 3.3.1 and Table 3-6, approximately 1,500 kt of waste rock was blasted and excavated from the Mine Site surface to develop the site for various facilities including the Mill, Truck Shop, Camp and CWP in preparation for operations. Construction of the Mine Site was initiated in September 2015 and continued during 2016, with the majority of excavation occurring in Q1 and Q2 of 2016 (Table 3-6). NPAG Quarry rock was used as fill for pad and road construction (excavation schedule provided in Table 3-49). A distinction is made for NPAG Quarry rock placed within the Mine Site which is included in the Mine Site runoff term, and for the NPAG Quarry rock placed outside the Mine Site, which reports to Brucejack Lake directly and is included with the NPAG Quarry N source terms (Section 3.8.4).

Table 3-49:

Source terms for N species were developed as instantaneous loads, and capture contributions from Mine Site runoff associated with exposures from surface excavation and placement of NPAG Quarry fill, as well as deposition of surface waste rock in Brucejack Lake. The surface waste rock load represents the mass of available soluble N species that is instantaneously released into solution upon contact with surface runoff or subaqueous deposition. The approach for derivation of each of these water quality model inputs are described in the sections below.

3.8.3.2 Surface Waste Rock

The method for deriving N species source terms for surface waste rock was modified from the approach developed for the 2015 MA-EMA Permits Application (Pretivm, 2015). The MA-EMA Permits Application estimated the total N loads from the explosive quantities and the excavation schedule based on literature values for surface mining (Ferguson and Leask, 1988; Cameron *et al.*, 2007; Baily *et al.*, 2013). The current (2018) modelling approach assigned a N loading rate that was estimated from: 1) the observed changes in the lake total N inventory attributable to waste rock deposition, and 2) the tracked tonnages of waste rock deposited to Brucejack Lake for the period January 2016 to January 2018. Surface waste rock and underground waste rock were deposited concurrently to Brucejack Lake, but at varying proportions over time; therefore, N load rates were derived for both surface and underground materials to fully account for the incremental change in the lake N inventory between each monitoring event. Mine Site construction was completed in early 2017; therefore, no significant amount of surface waste rock was deposited to the lake after December 2016.

The total N loading rate of surface waste rock was calculated to be 0.004 kg-N/t for the January 2016 to January 2017 monitoring period. The modelled surface waste rock loading rates were conservatively rounded up to 0.005 kg-N/t for the Base Case and 0.008 kg-N/t for the Upper Case. Further, 100% of the loads were assumed to be instantaneously released to the lake. The quantity of explosives used per tonne of surface rock blasted was assumed to be 0.3 kg/t (as reported by the blasting contractor).

The N species loading rates and total surface waste rock deposition records to Brucejack Lake (Table 3-6) were used to derive N loads for surface waste rock (Table 3-50). The total N loads were distributed between ammonia, nitrite and nitrate using the distribution for N source terms described in Table 3-48. Mine Site surface excavation is not expected to occur during the Operations Phase, and therefore surface waste rock loads were only derived for the Construction Phase.

Table 3-50:
Nitrogen Loads for Surface Waste Rock to Brucejack Lake

Phase	Year		Base Case			Upper Case		
			NH_3 Load (kg-N)	NO_2 Load (kg-N)	NO_3 Load (kg-N)	NH_3 Load (kg-N)	NO_2 Load (kg-N)	NO_3 Load (kg-N)

3.8.3.3 Mine Site Runoff

Mine Site runoff within the contact water management area is collected in the CWP and pumped to the WTP for treatment, ultimately reporting the Brucejack Lake via the WTP effluent or tailings slurry discharge. Surface runoff is described in Section 3.3.2. The Mine Site runoff source term includes CWP catchment drainage from all exposed blasted rock surfaces and from NPAG Quarry fill used for the construction of pads and roads.

The derivation of N species loads for Mine Site runoff was modified from the approach developed for the MA-EMA Permits Application (Pretivm, 2015), which was based on explosive quantities, excavation and construction schedules, as well as literature values for surface mining (Ferguson and Leask, 1988; Cameron *et al.*, 2007; Baily *et al.*, 2013). For the current modelling approach, a Mine Site runoff N loading rate was estimated to be a proportion of the loading rate derived for surface waste rock (Section 3.8.3.2), at 0.001 kg-

N/t and 0.002 kg-N/t for Base Case and Upper Case, respectively. These are considered reasonable estimates as only a small proportion of the excavation blasting residues will report to runoff (*i.e.*, the majority will remain on the waste rock surfaces deposited in the lake). Further, infiltration and rinsing of surfaces filled with NPAG Quarry rock is limited by building coverage; the water shedding characteristics of road and pad surfacing; and by winter snow removal, which reduces road, and mill and camp pad runoff during the spring melt period.

The N loads for Mine Site runoff were calculated using the N loading rates, surface excavation records, and the NPAG Quarry rock placement schedule (Table 3-49). Calculated N species loads for surface runoff during the Construction phase are presented in Table 3-51 below, with 100% of the loads assumed to report to Brucejack Lake instantaneously. The N loads were distributed between ammonia, nitrite and nitrate based on the distribution for N source terms presented in Table 3-48.

Table 3-51:
Nitrogen Loads for Runoff Associated with Surface Excavations

3.8.4 NPAG Quarry

3.8.4.1 Overview

The NPAG Quarry is located near the southeast end of Brucejack Lake, with runoff from this area reporting directly to Brucejack Lake. Approximately 886 kt of rock has been excavated from the NPAG Quarry since January 2015 to provide material for building foundations, roads, and other construction activities at the Mine Site. The excavation and surface fill schedules for the Construction Phase are provided in Table 3-49. During Operations, the excavated quarry rock is crushed and placed in the underground mine for road surfacing. The NPAG Quarry rock excavation schedule is assumed to be 54,000 t/yr for LOM. N species source terms were developed for drainage in contact with exposures in the NPAG Quarry as well as drainage from roads and pads constructed from NPAG Quarry rock.

Drainage from NPAG Quarry rock used for surface roads and pads constructed outside the Mine Site is assumed to report to Brucejack Lake and is included with the N loads for quarry runoff described below. The N loads associated with NPAG Quarry rock placement within the Mine Site catchment are included with Mine Site runoff (see Section 3.8.3.3). NPAG Quarry rock is also used for road surfacing in the underground mine and N contributions from this placement are captured in the derivation of mine water N source terms (Section 3.8.5.4).

3.8.4.2 NPAG Quarry Runoff

The N source terms for NPAG Quarry runoff were derived using the same methodology applied to Mine Site runoff that was described in Section 3.8.3.3, yielding loading rates of 0.001 kg-N/t and 0.002 kg-N/t for Base Case and Upper Case, respectively. The loading rates, along with schedules for NPAG quarry excavation and NPAG Quarry fill placement, were used to calculate N loads attributed to NPAG Quarry runoff.

The nitrogen loads associated with NPAG quarry runoff are presented in Table 3-52 and are applicable to both Scenario 1 and Scenario 2 mine waste schedules. The total N loads were distributed between ammonia, nitrite and nitrate based on the distribution for N source terms presented in Table 3-48.

Table 3-52:

3.8.5 Underground Mine

3.8.5.1 Overview

As described previously in Sections 3.4.2 and 3.6.1, remaining LOM development of the Brucejack underground mine will result in excavation of an estimated 5.3 Mt of waste rock and 18.4 Mt of ore. The waste deposition schedules for the two scenarios are provided in Table 3-13 (Scenario 1, to lake), Table 3-14 (Scenario 2, to lake) and Table 3-15 (Scenario 2, to backfill); whereas the ore schedule is presented in Section 3.6.1.

N source terms were developed for: 1) underground mine waste rock deposited in Brucejack Lake, and 2) contact water from the underground mine. Underground waste rock and mine water were derived as instantaneous loads. The underground mine water N loads represent the transfer of ore and waste blasting residues to mine water, whereas the waste rock N loads are transferred to Brucejack Lake or to backfill (Scenario 2).

3.8.5.2 Underground Mine Waste Rock

The method for deriving N species source terms for underground waste rock was modified from the approach used for the 2015 MA-EMA Permits Application (Pretivm, 2015), which estimated the total N loads from the explosive quantities and the excavation schedule based on literature values for surface mining (Ferguson and Leask, 1988; Cameron *et al.*, 2007; Baily *et al.*, 2013) and observations from field bin monitoring data. Subsequently, in the 2016 water quality model update for nitrogen compounds (Lorax, 2016b), the observed N loading from waste rock deposition to Brucejack Lake was used to derive N loads for waste rock based on explosives quantities and the excavation schedule.

The current (2018) methodology estimates N loading rates from the observed changes in total N inventory in Brucejack Lake attributable to waste rock deposition, and the tracked tonnages of waste rock deposited to the lake for the periods of January 2017 through January 2018 (Base Case) and September 2017 through January 2018 (Upper Case). During the period of record (January 2015 through January 2018), surface waste rock and underground waste rock were deposited concurrently to Brucejack Lake, but at varying proportions over time. As described previously in Section 3.8.3.2, the N loading rates for both surface and underground rock were derived to fully account for the incremental change in the lake N inventory between each monitoring event.

The N loading rate attributable to underground waste was estimated to be 0.14 kg-N/t for the period of record, which represents the Base Case source term. The underground waste N loads for September 2017 through January 2018 were observed to be slightly higher, with an estimated load rate of 0.17 kg-N/t, which is used to represent the Upper Case N

source term. Waste rock deposited in Brucejack Lake is assumed to instantaneously release 100% of the N load at the time of deposition. The mine development waste rock blasting methods consumed explosives at an average rate of 1.54 kg/t of blasted rock; it is assumed explosives will be used at a similar rate for the LOM.

The N loading rates and projected waste rock schedules (refer to Section 3.4.2) were used to calculate N loads for the Operations phase for both Scenario 1 (all underground waste rock is deposited in Brucejack Lake) and Scenario 2 (the amount of waste rock placed as backfill is maximized to the extent possible (3.4 Mt), with the remaining portion placed in Brucejack Lake) (Table 3-53 and Table 3-54 for Scenario 1 and 2, respectively). The total N loads were distributed between ammonia, nitrite and nitrate based on the distribution for N source terms presented in Table 3-48.

3.8.5.3 Waste Rock Backfill

For the 2015 MA-EMA Permits Application (Pretivm, 2015) and the 2016 model update (Lorax, 2016b), the total N loads for waste backfill were derived in the same manner as for waste placed in the lake (described previously in Section 3.8.5.2), with the N loads reporting instantaneously to Brucejack Lake. The current modelling approach uses the N source terms derived in Section 3.8.5.2, with an attenuation factor to estimate N loads released from waste backfill to mine water.

Under Scenario 2, waste rock will be backfilled into secondary mined out stopes with cemented paste backfill. The backfilled paste will likely limit groundwater contact with waste rock and it is expected that the majority of nitrogen species will remain within the backfill. Therefore, it is assumed that 80% of the N load associated with underground waste rock will be retained within the backfill, with the remainder instantaneously released to mine water. If waste rock is placed underground, monitoring of seepage from backfilled waste will be conducted to validate the modelling assumptions.

The Operations Phase N loads for waste backfill presented in Table 3-55 were estimated using the N loading rates for underground waste rock (Section 3.8.5.2), an 80% attenuation factor, and the Scenario 2 waste backfill schedule (Table 3-15). The loads were distributed between ammonia, nitrite and nitrate based on the distribution for N source terms presented in Table 3-48.

Table 3-55:
Nitrogen Loads for Underground Mine Waste Rock to Backfill (Scenario 2)

3.8.5.4 Underground Mine Water

As described in Section 3.4.3, the underground mine workings at the Brucejack Gold Mine occur primarily below the groundwater table, and thus dewatering of the workings is required for all active phases of the mine. The N species arising from explosives used for blasting waste rock and ore are transferred to underground mine water through the dissolution of N species at the blast location, both through contact with groundwater that enters the mine and contact with mine water used for dust suppression. Backfilled waste and cement paste will also contribute N to mine water; however, these contributions are accounted for separately in Section 3.8.5.3 (for waste) and Section 3.8.6.3 (for ore). The NPAG Quarry rock used for underground mine road surfacing contributes comparatively small loads to mine water; these loads are assumed to be captured in the derivation of the mine water N loading rate.

In the 2015 MA-EMA Permits Application (Pretivm, 2015) and the 2016 update to the water quality model for nitrogen compounds (Lorax, 2016b), the N loads from explosives to mine water were derived from water quality monitoring and records of explosives use, which were used to estimate an explosives loss rate. For the current study, mine water N loading rates were derived using water quality, dewatering, and excavation records from January 2015 through July 2017. Specifically, the N loads exported in the mine water and tonnages of underground mine rock excavated (blasted) were used to derive N loading rates per tonne of rock blasted. An N loading rate of 0.022 kg-N/t was calculated for the monitoring period of February 2015 through July 2017, and applied as the Base Case source term.

An elevated loading rate of 0.033 kg-N/t was observed during the September to December 2016 time period, when challenging blasting conditions were encountered that led to excessive explosives loss to mine water. Therefore, 0.033 kg-N/t was used for the Upper Case source term. It is assumed the explosives used per tonne of rock will remain relatively constant throughout the LOM, similar to observed rates of 1.54 kg/t for development (waste) blasting and 0.8 kg/t for production (ore) blasting.

The N loading rates and the waste rock and ore excavation schedules (refer to Section 3.4.2, Table 3-13, Table 3-14 and Table 3-15; and, Section 3.6.1, Table 3-42) were used to model N loads to mine water from underground blasting for the Construction and Operations phases. Predicted N loads for underground mine water for both Scenario 1 and Scenario 2 are presented in Table 3-56. The total N was distributed between ammonia, nitrite and nitrate based on the species distributions for N source terms presented in Table 3-48.

Table 3-56:
Nitrogen Loads for Underground Mine Water

Notes: * Year 1 (Y01) of operations consists of only seven months (June through December of 2017).

3.8.6 Mill Components

3.8.6.1 Overview

Nitrogen enters the mill through ore, mine water, slimes, and reclaim water from Brucejack Lake. The export of N from the mill (including via the WTP located within it) occurs by water supplied to the underground mine, backfill tailings paste, as well as discharges of WTP effluent and thickened tailings to the lake. The water quality model uses all the N source terms described in previous sections, as well as for ore (described below) to derive N species concentrations in the mill components of the GoldSim model as described in Section 3.6.1. The following sections describe N source terms developed for ore and the assumptions regarding the release of N loads from tailings and paste backfill.

3.8.6.2 Ore

The methods for estimating N loads from ore were modified from the approaches previously used in the 2015 MA-EMA Permits Application (Pretivm, 2015) and the 2016 update to the water quality model for N compounds (Lorax, 2016b). For the 2015 MA-EMA Permits Application, ore N source terms were not derived; rather, metallurgical test results from ore bulk samples were used to estimate N loads in Mill tailings slurry. Subsequently, in the 2016 water quality model update for N compounds, the observed loading rates from waste rock deposition to Brucejack Lake were used to derive N loads for ore. As per other N loads, it was assumed that 100% of the N residues on the ore surfaces would be transferred to tailings and report instantaneously to Brucejack Lake regardless of whether tailings were discharged to the lake or placed underground as paste backfill.

For the current assessment, the approach for estimating ore-related loads was updated based on mining records and monitoring data collected from the commencement of ore excavation and milling (June 2017) through January 2018. The production (ore) mining method uses the long-hole blasting technique rather than the short rounds used for mine development (waste) blasting. For the period of record the observed explosives consumption rate averaged 0.8 kg/t of ore, approximately 50% lower than observed for waste excavation (1.54 kg/t). It is assumed explosive usage for ore will average approximately 0.8 kg/t for the LOM.

The N loads on ore were derived from weekly monitoring conducted at the SAG mill, which is fed both ore and recycled process water for the ore grinding operation. The SAG mill influent and effluent water were monitored for nitrogen compounds (ammonia, nitrite, nitrate, and total nitrogen). The change in process water total N concentration was derived for each monitoring event, with the corresponding instantaneous process water flow and ore feed rates used to derive an instantaneous total N load rate per tonne of ore. Calculated

75th and 90th percentiles of load rates of 0.028 kg-N/t and 0.054 kg-N/t, respectively, were used to represent Base Case and Upper Case N loads for ore based on the projected ore production schedule (Table 3-42). The total N loads were distributed between ammonia, nitrite and nitrate based on the species distribution for N source terms presented in Table 3-48. The Operations phase ore-related N species loads, which apply to both Scenario 1 and Scenario 2, are presented in Table 3-57.

Table 3-57:
Nitrogen Loads for Ore to Mill

Phase	Year		Base Case			Upper Case		
			NH_3 Load (kg-N)	NO_2 Load (kg-N)	NO_3 Load (kg-N)	NH_3 Load (kg-N)	NO_2 Load (kg-N)	NO_3 Load (kg-N)

	Y14	Year 14	11,185	2,019	25,632	21,571	3,895	49,433

Notes: * Year 1 (Y01) of operations consists of only seven months (June through December of 2017).

3.8.6.3 Tailings and Paste Backfill Loads

As described above, the methods for deriving N loads for tailings and paste backfill were modified from the approaches previously used in the 2015 MA-EMA Permits Application (Pretivm, 2015) and the 2016 update to the water quality model for nitrogen compounds (Lorax, 2016b). For the 2015 MA-EMA Permits Application, metallurgical test results from ore bulk samples were used to estimate nitrogen loads in Mill tailings. Subsequently, in the 2016 water quality model update for nitrogen compounds, 100% of the derived N loads for ore were assumed to be transferred to tailings and report instantaneously to Brucejack Lake regardless of whether tailings were discharged to the lake or placed underground as paste backfill.

For this assessment, N loads associated with tailings discharged to the lake or placed underground as backfill were calculated by the GoldSim model on a monthly time step and

assigned entirely to the process water associated with the tailings. The predicted mill process water composition was calculated in GoldSim considering the flows and concentrations of components introduced to the mill (*i.e.*, WTP effluent, reclaim water, ore moisture and slime water), along with the loads added from the processed ore. Base Case and Upper Case process water quality predictions were based on the Base Case and Upper Case terms for the components introduced to the mill. The tailings placement schedule is provided in Table 3-42.

Tailings discharged to Brucejack Lake are assumed to instantaneously release 100% of the N loads into the lake. In contrast, tailings placed underground as paste backfill are assumed to sequester the majority of the nitrogen compounds within the cured cemented paste. As described previously in Section 3.6.6, porewater contained in paste backfill that is not consumed during the cement curing process will be released as bleed water. Bleed water quality is assumed to be equivalent to the predicted mill process water composition, representing a volume equal to approximately 2.5% of the water content in the paste. Although it is expected that the remaining N loads will be retained within the cured cemented paste, it is conservatively assumed that 80% of the N load remaining in the paste backfill (after accounting for bleed water) will be retained, and 20% will be instantaneously released to mine water. Monitoring of seepage from backfilled paste will be used to validate and refine modelling assumptions.

4. Results

4. Results

4.1 Overview

This section presents updated Brucejack Gold Mine water quality predictions for the proposed 3800 tpd production increase for two monitoring sites: 1) BJ 3.10, the mine's regulated discharge location at the outlet of Brucejack Lake; and 2) BJ 2.62, a downstream monitoring location in Brucejack Creek that will receive underground mine loads via groundwater pathways once the mine is flooded (Figure 1-1). Results for BJ 3.10 are therefore presented for the Operations, Closure and Post-closure mine phases; whereas water quality results at BJ 2.62 are only presented for the Closure and Post-closure phases. Water quality predictions at each monitoring site are discussed separately below.

For each monitoring site, results are presented for the two waste rock and tailings management strategies (*i.e.*., Scenario 1 and Scenario 2, Section 1 and 2.2.4) and compared to predictions presented in the 2015 MA-EMA Permits Application and relevant water quality guidelines or limits. As described in Section 1, the two scenarios represent the extremes of waste rock deposition to Brucejack Lake versus backfilled underground, with tailings discharge and paste tailings backfill balanced accordingly. Pretivm is seeking the authorization to manage these wastes according to operational needs. The water quality modelling approach is based on the logic that if both waste deposition extremes are acceptable, an 'in-between' approach would also be acceptable.

Predictions at BJ 3.10 are compared to discharge limits defined by Brucejack Gold Mine Effluent Permit 107835, whereas predictions at BJ 2.62 are compared to BC FWAL guidelines. Base Case and Upper Case water quality predictions are presented. The Base Case is considered to represent a conservative expected case; whereas the Upper Case incorporates the combined effects of upper case geochemical source terms for all inputs. Base Case and Upper Case maximum monthly predictions for both scenarios at BJ 3.10 and BJ 2.62 are presented in Appendix 3.

The discussion of the water quality predictions is focused on environmentally-relevant parameters showing mine-related signatures. Emphasis is placed on parameters which show significant changes from the 2015 MA-EMA Permits Application. Overall, general patterns observed for water quality predictions are related to: 1) the seasonal water balance and corresponding water quality; 2) geochemical behaviour of waste rock as a function of time (*e.g.*, the onset of ARD generation); and 3) deposition schedules for the various inputs to the lake (*e.g.*, waste rock, tailings, WTP effluent).

The water quality model predictions discussed in the following sections are presented as time series plots based on the current mine schedule. The Operations phase of the current mine plan is 14 years and is based on a calendar year (Section 2.2.1), whereas the 2015 MA-EMA Permits Application model was based on an 18-year Operations phase with mine years and associated mine phases starting in June of specified years. In order to provide a direct comparison of current and 2015 MA-EMA Permits Application results from the different mine phases, Operation phase results for the 2015 MA-EMA Permits Application model are not shown beyond year 14, and Closure and Post-closure predictions have been shifted accordingly.

4.2 Water Quality Predictions for BJ 3.10

4.2.1 Base Case Results

This section presents the Base Case water quality predictions for sulfate, nitrate, total arsenic (T-As) and total antimony (T-Sb) to illustrate how water quality in Brucejack Lake responds to key loading terms. Water quality time series plots are presented for these parameters alongside applicable water quality guidelines or discharge limits for reference. Tabulated results for all parameters are provided in Appendix 3-1. A summary of maximum Base Case BJ 3.10 water quality predictions as compared to the 2015 MA-EMA Permits Application predictions is presented in Table 4-1.

The BJ 3.10 comparisons show that maximum modelled predictions for several parameters are higher in the current Base Case model as compared to the 2015 MA-EMA Permits Application. These parameters include ammonia, nitrite, nitrate, dissolved aluminum (D-Al), T-Sb, T-As, dissolved iron (D-Fe), total lithium (T-Li) and total selenium (T-Se). Maximum predictions for D-Al, D-Fe, T-Li and T-Se are below BC FWAL guidelines and thus will not be discussed in detail in this application. Revised nitrogen predictions were presented in a previous amendment application (submitted in November 2016), but have been updated based on the increased ore production schedule and are therefore discussed below. Parameters which were previously predicted to exceed relevant guidelines, including nitrite, total phosphorus (T-P), total Chromium (T-Cr), total silver (T-Ag) and total zinc (T-Zn), are also discussed.

Table 4-1:
Maximum Concentrations from the BJ 3.10 Base Case Water Quality Model, for All Mine Phases, Compared to the Maximum from the 2015 MA-EMA Permits Application, BC Water Quality Guidelines, and PE-107835 Effluent Discharge Limits

Parameter	Units	Maximum Modelled		BC FWAL Guidelines		Effluent Discharge Limit

Notes: BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Concentrations that are higher in the current application than the 2015 MA-EMA Permits Application are shaded in grey.
Concentrations that exceed long-term guidelines are shown in **bold** font.
Concentrations that exceed short-term guidelines are shown as ***bold italic underlined*** font.
Hardness dependent guidelines calculated using the baseline median hardness of 28 mg/L as $CaCO_3$.
Ammonia guidelines assumes a pH of 8.0 and temperature of 15°C.
Chromium guideline is for Cr(VI).
NP=none proposed.

4.2.1.1 Sulfate

Although sulfate concentrations are not predicted to exceed the discharge limit, sulfate results are presented to provide context for ML/ARD-related processes. Sulfate concentrations within Brucejack Lake are predicted to gradually increase from background levels to maximum concentrations at the end of Operations (Figure 4-1). Lower sulfate concentrations are predicted for Scenario 1 (all future waste rock (5.3 Mt) is placed in Brucejack Lake) as compared to Scenario 2 (backfilling 3.4 Mt of waste rock in the underground mine), with maximum sulfate concentrations predicted to reach approximately 60 mg/L. Scenario 2 predictions are consistent with predictions from the 2015 MA-EMA Permits Application model (which incorporated waste rock backfill) and approach 100 mg/L SO_4 (Figure 4-2).

The observed increase in sulfate over the Operations phase is primarily due to the expansion of the underground mine and corresponding increased annual loading associated with tailings slurry discharges to Brucejack Lake (Figure 4-2 and Figure 4-3). The WTP does not treat for sulfate, and thus loadings from the WTP during periods of discharge will also contribute to the sulfate loads in Brucejack Lake and at BJ 3.10 (*i.e.*, during approximately one month of the year when the water is not recycled to the mill).

Sulfate concentrations are predicted to decrease through Closure, as ore processing, tailings disposal and effluent discharges from the WTP cease, and are expected to return to background levels within approximately five years following mine closure.

Figure 4-1: Base Case sulfate concentration predictions at BJ 3.10 (Brucejack Lake) through Operations and Post-closure mine phases.

Figure 4-2: Sources of sulfate loadings (kg/month) to Brucejack Lake during Operations phase for the Scenario 1 Mine Schedule.

Figure 4-3: Sources of sulfate loadings (kg/month) to Brucejack Lake during Operations phase for the Scenario 2 Mine Schedule.

4.2.1.2 Ammonia

Concentrations of ammonia in Brucejack Lake are predicted to increase through the first few years of Operations, as mining activities progress, and remain relatively stable at approximately 2.5 mg/L throughout most of Operations (Figure 4-4). Slightly lower ammonia concentrations are predicted for Scenario 2, where a portion of the waste rock is backfilled in the underground mine. Ammonia originates primarily from blasting residues arising from explosives use; therefore, ammonia concentrations in Brucejack Lake are largely associated with placement of waste rock and tailings in the lake (Figure 4-5 and Figure 4-6). As described previously (Section 3.8.2) secondary microbially-mediated

nitrification processes promote non-conservative behavior of ammonia in Brucejack Lake. However, to address uncertainty regarding the rate of nitrification, conservative behaviour is modelled for ammonia and this represents an upper ammonia concentration endpoint for low rates of nitrification.

Concentrations of ammonia for the 3800 tpd updated water quality model are predicted to be higher than those predicted in the 2015 MA-EMA Permits Application model and exceed the discharge limit (1.0 mg/L) throughout Operations (Figure 4-4). The reason for the increase in ammonia predictions in the current model as compared to the 2015 MA-EMA Permits Application model relates to the approach for deriving N source terms, rather than the proposed ore production increase. Ammonia source terms for the 2015 MA-EMA Permits Application (Pretivm, 2015) were derived using generally accepted approaches for modelling nitrogen species (ammonia, nitrite and nitrate) based on literature values for surface mines, Exploration phase monitoring data and metallurgical bench scale testing. Site-specific monitoring data collected during the Construction and early Operation phases of Brucejack Gold Mine were used to review and revise N source terms as described in Section 3.8 and in a previous amendment application (submitted in November 2016). The data indicates that the original (2015) model assumptions underestimated the quantity of nitrogen released from ore and waste, noting that blasting residues on ore are transferred to tailings during milling. The updated ammonia source terms, in addition to the increased excavation and explosives use projected for the current (2018) amendment application, account for the increase in predicted ammonia concentrations compared to the previous (2015) predictions.

The concentration of ammonia is expected to decrease steadily after Operations, decreasing below the discharge limit during Closure, and returning to background levels within approximately five years of mine closure.

Figure 4-4: Base Case ammonia concentration predictions at BJ 3.10 (Brucejack Lake) through Operations and Post-closure mine phases.

Figure 4-5: Sources of ammonia loadings to Brucejack Lake during Operations phase for Scenario 1 Mine Schedule.

Figure 4-6: Sources of ammonia loadings to Brucejack Lake during Operations phase for Scenario 2 Mine Schedule.

4.2.1.3 Nitrite

Nitrite concentrations within Brucejack Lake are predicted to gradually increase through the first few years of Operations, as blasting activities in the mine increase, and reach a maximum of 0.20 mg/L (Figure 4-7). Slightly lower nitrite concentrations are predicted for Scenario 2. As described in Section 3.8, and for ammonia (Section 4.2.1.2), the extensive investigations undertaken since 2015 quantify nitrogen release from waste rock and tailings at a higher rate than previously assumed for the 2015 predictions; but nitrite

concentrations are not expected to exceed the discharge limit (0.24 mg/L) at any point throughout LOM for both Base Case scenarios.

Nitrite originates primarily from blasting residues arising from explosives use. Therefore, concentrations of nitrite decrease later in mine life, as mining shifts to the West Zone, and the rate of blasting and explosives quantities used for blasting decrease. The concentration is expected to decrease steadily through Closure, after the cessation of blasting, with concentrations returning to background levels within approximately five years of mine closure.

Figure 4-7: Base Case nitrite concentration predictions at BJ 3.10 (Brucejack Lake) through Operations and Post-closure mine phases.

4.2.1.4 Nitrate

Concentrations of nitrate in Brucejack Lake for both Base Case scenarios are predicted to increase through the first few years of Operations, as mining activities progress, and reach a maximum of 8.7 mg/L (Figure 4-8). Values are predicted to be slightly lower (up to 7.5 mg/L) for Scenario 2 where a portion of the waste rock is backfilled in the underground mine. The nitrate concentrations are largely associated with waste rock and tailings placement in the lake (Figure 4-9 and Figure 4-10).

Nitrate originates primarily from blasting residues arising from explosives use. As described in Section 3.8, and for ammonia (Section 4.2.1.2) and nitrite (Section 4.2.1.3), the extensive investigations undertaken since 2015 quantify nitrogen release from waste rock and tailings at a higher rate than derived for the 2015 predictions. As described in Section 3.8.2 and Section 4.2.1.2, secondary microbially-mediated nitrification processes in Brucejack Lake convert ammonia and nitrite to nitrate. Nitrate predictions conservatively assume a high nitrification rate and thus represent upper nitrate concentration endpoints. The predicted concentrations of nitrate are not expected to exceed the discharge limit (11.5 mg/L) at any point during LOM.

Concentrations of nitrate are predicted to decrease later in mine life, as mining shifts to the West Zone, and the rate of blasting decreases. The concentration of nitrate is expected to

decrease steadily through Closure, with concentrations returning to background levels within approximately five years of mine closure.

Figure 4-8: Base Case nitrate concentration predictions at BJ 3.10 (Brucejack Lake) through Operations and Post-closure mine phases.

Figure 4-9: Sources of nitrate loadings to Brucejack Lake during Operations phase for Scenario 1 Mine Schedule.

Figure 4-10: Sources of nitrate loadings to Brucejack Lake during Operations phase for Scenario 2 Mine Schedule.

4.2.1.5 Arsenic

Concentrations of T-As in Brucejack Lake are predicted to increase above the discharge limit (0.005 mg/L) early in the Operations phase (Figure 4-11). Concentrations of As are predicted to be higher for Scenario 1, which places all future waste rock in the lake, with concentrations predicted to reach a maximum of 0.0065 mg/L in Y03, and continue to periodically exceed the discharge limit throughout the Operations phase. Concentrations of As in Brucejack Lake are predicted to be lower for Scenario 2 in comparison to Scenario 1 (by 0.0010 to 0.0015 mg/L), with a maximum of 0.0058 mg/L As attained by Y03. Concentrations of As are predicted to progressively decrease after Y03, decreasing below the discharge limit by Y05.

Concentrations of As in Brucejack Lake are primarily influenced by the proportion of underground waste rock submerged in the lake (Figure 4-12 and Figure 4-13) and to a lesser extent the tailings slurry. Background levels are also relatively high, and are expected to contribute to the elevated concentrations of As in Brucejack Lake during Operations.

Concentrations are expected to diminish to near background levels in Brucejack Lake Post-closure for Scenario 2; however, the model predicts that As will be sustained at a slightly higher concentration (0.003 mg/L) throughout Post-closure if all waste rock is placed in the lake (Scenario 1).

Figure 4-11: Base Case total arsenic concentration predictions at BJ 3.10 (Brucejack Lake) through Operations and Post-closure mine phases.

Figure 4-12: Sources of total arsenic loadings to Brucejack Lake during Operations phase for Scenario 1 Mine Schedule.

Figure 4-13: Sources of total arsenic loadings to Brucejack Lake during Operations phase for Scenario 2 Mine Schedule.

4.2.1.6 Antimony

Concentrations of T-Sb are predicted to gradually increase in Brucejack Lake throughout Operations for both Base Case scenarios and reach a maximum of 0.013 mg/L at the end of Operations (Figure 4-14). Concentrations are predicted to exceed the BC FWAL working guideline (0.009 mg/L) by Y05 and continue to exceed the guideline on a seasonal basis throughout Operations. The concentrations of Sb are predicted to be higher than the concentrations predicted by the 2015 MA-EMA model.

Figure 4-14: Base Case total antimony concentration predictions at BJ 3.10 (Brucejack Lake) through Operations and Post-closure mine phases.

The Sb load to Brucejack Lake is primarily associated with tailings slurry discharges (Figure 4-15 and Figure 4-16). The WTP does not treat for antimony, and thus loadings from the WTP during periods of discharge will also contribute to the antimony loads in Brucejack Lake and at BJ 3.10 (*i.e.*, during approximately one month of the year, when the water is not recycled to the mill).

Concentrations are predicted to decrease through Closure, as ore processing, tailings disposal and effluent discharges from the WTP cease, and are expected to return to background levels within approximately five years of mine closure.

Figure 4-15: Sources of total antimony loadings (kg/month) to Brucejack Lake during Operations phase for Scenario 1 Mine Schedule.

Figure 4-16: Sources of total antimony loadings (kg/month) to Brucejack Lake during Operations phase for Scenario 2 Mine Schedule.

4.2.1.7 Phosphorus

Total P is predicted to increase steadily in Brucejack Lake throughout Operations and reach a maximum of 0.027 mg/L (Figure 4-17). Concentrations of P are predicted to be lower than the concentrations predicted by the 2015 MA-EMA model. The increase in P over time is attributed to a number of different sources, including STP effluent, WTP effluent and Tailings slurry discharge. Concentrations are predicted to decrease through Closure and return to background levels early in Post-Closure.

Figure 4-17: Base Case total phosphorus concentration predictions at BJ 3.10 (Brucejack Lake) through Operations and Post-closure mine phases.

4.2.1.8 Chromium

Concentrations of T-Cr in Brucejack Lake are predicted to be low and remain low (<0.0005 mg/L) throughout most of Operations for both Base Case scenarios following an initial influx of approximately 0.0010 mg/L. Concentrations of Cr are primarily associated with tailings discharges, background contributions and effluent from the WTP. Total Cr is expected to leach from cemented paste backfill underground, which will be primarily in

hexavalent form (Cr(VI)). The WTP does not treat for Cr(VI), only Cr(III), and thus loadings from the WTP during periods of discharge are expected to contribute to the total Cr loads in Brucejack Lake and at BJ 3.10 (*i.e.*, during one month of the year, when the water is not recycled to the mill).

The 2015 MA-EMA model had predicted that Cr concentrations would increase in steps through early Operations, to a maximum concentration of approximately 0.010 mg/L in Brucejack Lake when it would exceed the discharge limit of 0.009 mg/L (Figure 4-18). The elevated predictions resulted in evaluation of potential source control contingency measures that reduce Cr(VI) to Cr(III) using emerging industry best practices (Chromium Management Plan). In contrast, Operational monitoring of influent water quality to the WTP has shown that the Cr(VI) level has remained below the discharge limit and well below the original predictions.

Total Cr is expected to decrease further through Closure and return to background levels Post-closure, when cemented paste backfill is no longer being placed underground.

Figure 4-18: Base Case total chromium concentration predictions at BJ 3.10 (Brucejack Lake) through Operations and Post-closure mine phases.

4.2.1.9 Silver

For both Base Case scenarios, concentrations of T-Ag are predicted to increase in Brucejack Lake throughout Operations from relatively high background levels to steady-state concentrations lower than the 2015 MA-EMA model predictions and an order of magnitude below the discharge limit (0.00046 mg/L) (Figure 4-19). Silver is naturally elevated in the upper Brucejack system and occurs in economic concentrations within the mine. The primary sources of Ag to Brucejack Lake are therefore anticipated to be tailings slurry discharges and background contributions. As a result, concentrations of Ag are predicted to be higher for Scenario 2 in comparison to Scenario 1, reflecting the increased tailings deposition in the lake.

Concentrations are predicted to decrease throughout Closure and return to background levels early in Post-Closure.

Figure 4-19: Base Case total silver concentration predictions at BJ 3.10 (Brucejack Lake) through Operations and Post-closure mine phases.

4.2.1.10 Zinc

Concentrations of T-Zn in Brucejack Lake are predicted to decrease at the beginning of Operations to steady state concentrations of approximately 0.0020 mg/L throughout Operations for both 3800 tpd production increase Base Case scenarios (Figure 4-20). These updated predictions for Zn are lower in comparison to the 2015 MA-EMA model, which predicted that concentrations would initially increase in Brucejack Lake to a maximum of 0.0051 mg/L and remain elevated throughout Operations.

Similar to total As and Ag, background levels are predicted to be the dominant source of Zn to Brucejack Lake. Tailings slurry discharges to the lake are also expected to contribute to the initial minor increase in Zn above the background concentration. Concentrations of Zn are expected to return to background levels during the Closure phase.

Figure 4-20: Base Case total zinc concentration predictions at BJ 3.10 (Brucejack Lake) through Operations and Post-closure mine phases.

4.2.2 Upper Case Results

In general, the Base Case results summarized above represent conservative water quality predictions for the Brucejack Gold Mine Project, which make a reasonable allowance for any potential variability in model input, and generally do not account for secondary reactions that may occur underground or in Brucejack Lake that could potentially attenuate elevated concentrations of nutrients and other anions, and metals. However, some residual

uncertainty remains, and an Upper Case scenario, whereby ML/ARD develops more rapidly and to a greater extent than expected in the underground mine, was modelled to evaluate potential effects of factors that could lead to higher than expected concentrations for certain water quality parameters.

As discussed in Section 3, the Upper Case source terms are generally based on 90th percentile values from geochemical datasets for all mine-related flows and employs highly conservative assumptions with respect to both contact water chemistry (as 90th percentiles) and onset of acidity. Not surprisingly, this model case predicts notable increases for several parameters compared to the Base Case.

Predicted Upper Case concentrations for sulfate, T-As and T-Sb in Brucejack Lake are presented, as these parameters are strongly influenced by the time to onset and severity of ML/ARD. The predicted Upper Case concentrations of nitrite and nitrate are also presented as revised predictions (Lorax, 2016b) since these were updated in a previous amendment application (submitted in November 2016). Water quality time series plots are presented for these parameters. Tabulated results for all parameters (as monthly maxima by mine phase) are provided in Appendix 3-1.

4.2.2.1 Sulfate

Upper Case predictions of sulfate in Brucejack Lake show a progressive increase throughout Operations for both scenarios and exceed the BC FWAL 30-day guideline (128 mg/L) (Figure 4-21). Concentrations of sulfate for Scenario 2 (a portion of waste rock is backfilled in the underground mine) are predicted to increase to approximately 175 mg/L by the end of Operations, whereas concentrations for Scenario 1 (all waste rock is placed in Brucejack Lake) are predicted to be slightly lower (up to 150 mg/L).

Concentrations of sulfate for both scenarios are predicted to decrease through Closure and return to background levels early in Post-closure.

Figure 4-21: Upper Case sulfate concentration predictions at BJ 3.10 (Brucejack Lake) through Operations and Post-closure mine phases.

4.2.2.2 Ammonia

Upper Case predictions of ammonia in Brucejack Lake follow the same trend as the Base Case predictions under both Mine Schedule scenarios (Figure 4-22), with Scenario 1 predicting slightly higher concentrations. Upper Case predictions increase during the first half of Operations to a maximum of 4.0 mg/L and are predicted to exceed the discharge limit (1.0 mg/L) throughout all of Operations. Conservative behaviour is modelled for ammonia and this represents an upper ammonia concentration endpoint for low rates of nitrification. The concentration of ammonia is predicted to decrease rapidly during Closure and return to background levels during Post-Closure.

Figure 4-22: Upper Case ammonia concentration predictions at BJ 3.10 (Brucejack Lake) through Operations and Post-closure mine phases.

4.2.2.3 Nitrite

Upper Case predictions of nitrite in Brucejack Lake follow the same trend as the Base Case predictions under both Mine Schedule scenarios (Figure 4-23), with Scenario 1 predicting slightly higher concentrations. Upper Case predictions increase during the first half of Operations to a maximum of 0.28 mg/L, slightly above the discharge limit (0.24 mg/L). The concentration of nitrite is predicted to decrease rapidly during Closure and return to background levels during Post-Closure.

Figure 4-23: Upper Case nitrite concentration predictions at BJ 3.10 (Brucejack Lake) through Operations and Post-closure mine phases.

4.2.2.4 Nitrate

Upper Case predictions for nitrate in Brucejack Lake follow a similar profile for both scenarios but at higher concentrations than the Base Case predictions (Figure 4-24). A high nitrification rate that enriches nitrate in the lake is conservatively assumed for nitrate predictions representing an upper endpoint for nitrate concentrations. Upper Case concentrations of nitrate show an increase over the first six years of Operations to a maximum of approximately 12.2 mg/L, slightly above the discharge limit (11.5 mg/L). The concentration of nitrate is only slightly lower for Scenario 2, where a portion of the waste rock is backfilled in the underground mine. Concentrations of nitrate are predicted to decrease rapidly throughout Closure as blasting activities cease and return to background levels early in Post-closure.

Figure 4-24: Upper Case nitrate concentration predictions at BJ 3.10 (Brucejack Lake) through Operations and Post-closure mine phases.

4.2.2.5 Arsenic

Upper Case predictions of T-As in Brucejack Lake show notably different concentration profiles for the two scenarios (Figure 4-25), reflecting the different waste rock placement strategies. Upper Case concentrations of As at BJ 3.10 for Scenario 1 are predicted to increase rapidly over the first four years of Operations to values nearly twice the predicted values for Base Case and well above the discharge limit (0.005 mg/L). Under this scenario which places all waste rock in Brucejack Lake, Upper Case predictions for As would consistently exceed the current discharge limit at BJ 3.10 throughout the LOM, and reach a maximum of 0.010 mg/L near the end of Operations. Upper Case concentrations of As at BJ 3.10 for Scenario 2 are predicted to reach a maximum of 0.0078 mg/L in Y02 and progressively decrease throughout the rest of Operations, only exceeding the discharge limit on a seasonal basis.

Concentrations of As are predicted to decrease below the discharge limit for both scenarios during the Closure phase and remain low throughout Post-closure (<0.0025 mg/L).

Figure 4-25: Upper Case total arsenic concentration predictions at BJ 3.10 (Brucejack Lake) through Operations and Post-closure mine phases.

4.2.2.6 Antimony

Upper Case concentrations of T-Sb at BJ 3.10 are predicted to increase consistently throughout Operations for both scenarios to a maximum of approximately 0.028 mg/L at the end of the Operations phase (Figure 4-26). Upper Case concentrations of Sb would increase above the BC FWAL 30-day guideline (0.009 mg/L) in Y03 and remain above the guideline until the end of the Closure period. Concentrations of Sb at BJ 3.10 would be expected to return to background levels (~0.00050 mg/L) early in the Post-closure period.

Figure 4-26: Upper Case total antimony concentration predictions at BJ 3.10 (Brucejack Lake) through Operations and Post-closure mine phases.

4.3 Water Quality Predictions for BJ 2.62

4.3.1 Base Case Results

The section presents Base Case water quality predictions at the downstream monitoring location in Brucejack Creek (BJ 2.62) for sulfate, ammonia, nitrite, nitrate, T-As, T-Sb and T- and D-Fe to illustrate how water quality in Brucejack Creek is predicted to respond to loads from the flooded underground mine via groundwater pathways during Closure and Post-Closure project phases. Water quality time series plots are presented for these parameters alongside applicable water quality guidelines and the 2015 MA-EMA predictions for reference. Tabulated results for all parameters are provided in Appendix 3-2.

A summary of maximum Base Case model results during LOM is presented in Table 4-2. The BJ 2.62 comparisons show that predictions for the 3800 tpd production increase application are higher than predictions in the 2015 MA-EMA Permits Application for ammonia, nitrite, nitrate, Cl, F, D-Al, T-Sb, T-As and D-Fe, T-Se and T-Zn. Revised nitrogen predictions were presented in a previous amendment application (submitted in November 2016), but have been updated based on the increased ore production schedule and are therefore discussed below. Maximum predictions for Cl, F, D-Al and T-Se are below BC FWAL guidelines and will not be discussed in this application. Parameters which were previously predicted to exceed relevant guidelines, including T-Ag, T-Be, T-Cr, T-Cu, T-P and T-Zn, are also presented.

Table 4-2:
Maximum Concentrations from the BJ 2.62 Base Case Water Quality Model for Operations and Post-closure Mine Phases, Compared to the Maximum from the 2015 MA-EMA Permits Application, BC Water Quality Guidelines, and PE-107835 Effluent Discharge Limits

Parameter	Units	Maximum Modelled		BC FWAL Guidelines		Effluent Discharge Limit
		2017 Application	2015 MA-EMA	Long-term	Short-term	
Ammonia	mg-N/L	**2.8**	0.44	1.1	5.7	1.0

Notes: BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Concentrations that are higher in the current application than the 2015 MA-EMA Permits Application are shaded in grey.
Concentrations that exceed long-term guidelines are shown in **bold** font.
Concentrations that exceed short-term guidelines are shown as **bold italic underlined** font.
Hardness dependent guidelines *calculated using the baseline median hardness of* 28 mg/L as $CaCO_3$.
Ammonia guidelines assumes a pH of 8.0 and temperature of 15°C.
Chromium guideline is for Cr(VI).
NP=none proposed.

4.3.1.1 Sulfate

Concentrations of sulfate within Brucejack Creek (Figure 4-27) are predicted to be similar to predictions made in the 2015 MA-EMA model and remain below the BC FWAL 30-day guideline. The concentration profile for sulfate at BJ 2.62 shows seasonal fluctuations and an overall gradual decrease throughout Closure, with values returning to background ranges during Post-Closure.

Concentrations of sulfate at BJ 2.62 reflect concentrations at BJ 3.10, which are primarily derived from tailings slurry deposition in Brucejack Lake and seasonal background contributions from Camp Creek (Table 3-2, Figure 4-2 and Figure 4-3). No additional contributions of sulfate are anticipated via groundwater flow from the flooded mine.

Figure 4-27: Base Case sulfate concentration predictions at BJ 2.62 through Closure and Post-closure mine phases.

4.3.1.2 Ammonia

Concentrations of ammonia at BJ 2.62 in upper Brucejack Creek are predicted to be initially elevated above the FWAL 30-day (1.1 mg/L) guideline, but below the FWAL maximum (5.7 mg/L) at the beginning of Closure for both scenarios (Figure 4-28). During Closure, the concentrations of ammonia are predicted to be higher than modelled for the 2015 MA-EMA Permits Application due to revisions to the approach for deriving N loads and the increased production rate. Ammonia concentrations are predicted to decrease below the FWAL 30-day guideline during Closure due to the cessation of blasting and deposition of waste in Brucejack Lake.

Concentrations of ammonia at BJ 2.62 reflect the elevated concentrations at BJ 3.10 (Figure 4-4), which are principally from blasting residues on waste rock and tailings deposited in Brucejack Lake. As described previously (Section 3.8.2) secondary microbially-mediated nitrification processes promote non-conservative behavior of ammonia in Brucejack Lake. To address uncertainty regarding the rate of nitrification, conservative behaviour is modelled for ammonia to represent an upper ammonia concentration endpoint consistent low rates of nitrification. Once blasting activities cease, no additional contributions are expected via groundwater flow from the flooded underground mine.

Figure 4-28: Base Case ammonia concentration predictions at BJ 2.62 through Closure and Post-closure mine phases.

4.3.1.3 Nitrite

Concentrations of nitrite at BJ 2.62 in upper Brucejack Creek are predicted to be initially elevated above the FWAL 30-day (0.020 mg/L) and maximum (0.060 mg/L) guidelines at the beginning of Closure for both scenarios (Figure 4-29). During Closure, the concentrations of nitrite are predicted to be higher than modelled for the 2015 MA-EMA Permits Application due to revision of the nitrite source terms as was discussed previously in Section 4.2.1.2. Nitrite concentrations are predicted to decrease below the maximum guideline during Closure and below the 30-day guideline during Post-Closure due to the cessation of blasting and deposition of waste in Brucejack Lake.

Concentrations of nitrite at BJ 2.62 reflect the elevated concentrations at BJ 3.10 (Figure 4-7), which are principally from blasting residues on waste rock and tailings deposited in Brucejack Lake. Once blasting activities cease, no additional contributions are expected via groundwater flow from the flooded underground mine.

Figure 4-29: Base Case nitrite concentration predictions at BJ 2.62 through Closure and Post-closure mine phases.

4.3.1.4 Nitrate

Concentrations of nitrate at BJ 2.62 in upper Brucejack Creek are predicted to be initially elevated above the FWAL 30-day (3.0 mg/L) guideline at the beginning of Closure for both scenarios (Figure 4-30) and higher than the concentrations predicted by the 2015 MA-EMA model. The increase is due to revision of the nitrite source terms for the current (2018) water quality model as was discussed previously in Section 4.2.1.3. Slightly higher concentrations of nitrate are predicted for Scenario 1 (5.8 mg/L) in comparison to Scenario 2 (5.3 mg/L), reflecting the increased waste rock placement in the lake for Scenario 1. Concentrations of nitrate are predicted to decrease rapidly to concentrations below the guideline during Closure and return to background levels Post-closure.

Concentrations of nitrate at BJ 2.62 reflect the elevated concentrations at BJ 3.10 Figure 4-8), which are derived primarily from blasting residues on waste rock and tailings deposited in Brucejack Lake. As described in Section 3.8.2, secondary microbially-mediated nitrification processes in Brucejack Lake convert ammonia and nitrite to nitrate. Nitrate predictions conservatively assume a high nitrification rate in the lake and thus represent upper nitrate concentration endpoints. Once blasting activities cease, no additional contributions are expected via groundwater flow from the flooded underground mine.

Figure 4-30: Base Case nitrate concentration predictions at BJ 2.62 through Closure and Post-closure mine phases.

4.3.1.5 Arsenic

Concentrations of T-As at BJ 2.62 in upper Brucejack Creek are predicted to show strong seasonal fluctuations and exceed the BC FWAL maximum guideline (0.005 mg/L) on a seasonal basis throughout Closure and Post-closure for both scenarios (Figure 4-31). Seasonally high concentrations of ~0.010 mg/L As are predicted for both Base Case scenarios. Concentrations of As are predicted to be lower than the concentrations predicted by the 2015 MA-EMA model, which predicted maximum values of 0.033 mg/L As during Closure.

Concentrations of As in Upper Brucejack Creek throughout the Closure and Post-closure phases are predicted to be higher by up to an order of magnitude in comparison to concentrations in Brucejack Lake (Figure 4-11), reflecting the additional As contributions in groundwater flow from the flooded underground mine.

Figure 4-31: Base Case total arsenic concentration predictions at BJ 2.62 through Closure and Post-closure mine phases.

4.3.1.6 Antimony

Concentrations of T-Sb at BJ 2.62 in upper Brucejack Creek are predicted to exceed the BC FWAL maximum guideline (0.009 mg/L) on a seasonal basis throughout the Closure phase for both Base Case scenarios (Figure 4-32). Concentrations of Sb are predicted to

decrease from ~0.014 mg/L to below the FWAL guideline at the end of Closure and remain low (0.0020 mg/L) throughout Post-closure.

Concentrations of Sb in upper Brucejack Creek are predicted to be slightly higher in comparison to the concentrations predicted for Brucejack Lake (BJ 3.10) Post-closure (<0.0010 mg/L), reflecting minor contributions from the flooded underground mine via subsurface flow.

Figure 4-32: Base Case total antimony concentration predictions at BJ 2.62 through Closure and Post-closure mine phases. Note that the current Base Case profiles overlap.

4.3.1.7 Iron

Concentrations of T-Fe and D-Fe show strong seasonal fluctuations in upper Brucejack Creek and are predicted to exceed the respective BC FWAL maximum guidelines (1.0 and 0.30 mg/L) on a seasonal basis at BJ 2.62 throughout Closure and Post-closure for both Base Case scenarios (Figure 4-33). Concentrations of Fe in Brucejack Creek are initially below the guideline at the beginning of Closure, but are predicted to increase to seasonal maxima of approximately 3.3 mg/L T-Fe and 3.0 mg/L D-Fe during Post-closure. Higher concentrations of Fe are predicted in comparison to the 2015 MA-EMA model, with D-Fe comprising a majority of the T-Fe.

Concentrations of T-Fe in Brucejack Lake is predicted to be relatively stable at 0.20 mg/L throughout Closure and Post-closure (Appendix 3.2), demonstrating that the elevated concentrations of T-Fe and D-Fe during the Post-closure phases are primarily attributed to inputs via groundwater flow from the flooded underground workings, and seasonal background contributions from Camp Creek (Table 3-2).

Figure 4-33: Base Case concentration predictions for total iron (upper plot) and dissolved iron (lower plot) at BJ 2.62 through Closure and Post-closure mine phases. Note that the current Base Case profiles overlap.

4.3.1.8 Silver

Concentrations of T-Ag in upper Brucejack Creek are predicted to exceed the BC FWAL 30-day guideline (0.000050 mg/L) on a seasonal basis during Closure for both Base Case scenarios (Figure 4-34). Silver is predicted to decrease through Closure and remain low (<0.000045 mg/L) and below the guidelines throughout Post-closure. Predicted values for silver are lower by nearly an order of magnitude in comparison to concentrations predicted by the 2015 MA-EMA model.

The concentration profile for Ag in Brucejack Creek is similar to that of Brucejack Lake; however, a slightly higher concentration is noted in the creek through Post-closure. The slightly higher concentrations of Ag in Brucejack Creek in comparison to Brucejack Lake indicate a potential minor contribution of Ag to the creek via groundwater flows from the flooded underground mine and/or seasonal background contributions from Camp Creek (Table 3-2).

Figure 4-34: Base Case concentration predictions for total silver at BJ 2.62 through Closure and Post-closure mine phases.

4.3.1.9 Zinc

Concentrations of T-Zn at BJ 2.62 in upper Brucejack Creek show seasonal fluctuations (~0.0035 to ~0.0075 mg/L) which are predicted to periodically approach the BC FWAL 30-day guideline (0.0075 mg/L) during the Closure and Post-closure phases for both Base Case scenarios (Figure 4-35). The current predictions are slightly lower in comparison to the 2015 MA-EMA model predictions. Concentration ranges in Brucejack Creek are higher in comparison to Brucejack Lake (~0.0020 mg/L), reflecting seasonally high background contributions from Camp Creek (Table 3-2).

Figure 4-35: Base Case total zinc concentration predictions at BJ 2.62 through Closure and Post-closure mine phases. Note that the current Base Case profiles overlap.

4.3.1.10 Phosphorus

Concentrations of T-P at BJ 2.62 in Brucejack Creek are predicted to be low at the end of Operations (0.020 mg/L) and decrease throughout Closure and Post-closure (Figure 4-36). Current predictions are lower in comparison to the 2015 MA-EMA model, which predicted that P would show large seasonal fluctuations in Brucejack Creek and reach a maximum value of 0.12 mg/L during Closure. Concentrations of P in Brucejack Creek during Post-closure reflect concentrations predicted for Brucejack Lake indicating little to no additional contributions from other sources.

Figure 4-36: Base Case total phosphorus concentration predictions at BJ 2.62 through Closure and Post-closure mine phases.

4.3.1.11 Chromium

Concentrations of T-Cr at BJ 2.62 in Brucejack Creek are predicted to be low and below the BC FWAL 30-day guideline (0.0010 mg/L) throughout Closure and Post-closure for both Base Case scenarios (Figure 4-37). Current model predictions are lower throughout the Closure phase in comparison to the 2015 MA-EMA model, which predicted that Cr would be elevated in Brucejack Creek at the end of Operations and decrease in steps throughout mine Closure. Concentrations of Cr in Brucejack Creek are predicted to have minor seasonal fluctuations (0.00020 to ~0.00065 mg/L), but at ranges generally slightly higher than in Brucejack Lake (0.00015 to ~0.00018 mg/L) through Post-closure, reflecting minor contributions from the flooded underground mine as well as seasonal background contributions from Camp Creek (Table 3-2).

Figure 4-37: Base Case total chromium concentration predictions at BJ 2.62 through Closure and Post-closure mine phases.

4.3.1.12 Copper

Concentration of T-Cu at BJ 2.62 in Brucejack Creek are predicted to show seasonal fluctuations ranging from 0.00056 to 0.0016 mg/L, but remain stable and well below the BC FWAL 30-day (0.0020 mg/L) and maximum (0.0046 mg/L) guidelines through Closure and Post-closure for both Base Case scenarios (Figure 4-38). Current predictions

for Closure are lower in comparison to the 2015 MA-EMA predictions, which showed large seasonal fluctuations of up to a maximum of nearly 0.007 mg/L T-Cu and exceeded the maximum guideline on a seasonal basis. Predicted concentrations of Cu in Brucejack Creek are similar to the predicted concentrations in Brucejack Lake (~0.00047 – 0.00053 mg/L), reflecting natural background concentration ranges in the creek (Table 3-3).

Figure 4-38: Base Case total chromium concentration predictions at BJ 2.62 through Closure and Post-closure mine phases. Note that the current Base Case profiles overlap.

4.3.2 Upper Case Results

The Base Case results summarized above represent conservative water quality predictions for upper Brucejack Creek and make a reasonable allowance for any potential variability in model input. However, as discussed in Section 4.2.2, some residual uncertainty remains and an Upper Case scenario, whereby ML/ARD develops more rapidly and to a greater extent than expected in the underground mine after Operations have ceased, was modelled to evaluate potential effects from groundwater flow that could lead to higher than expected concentrations for certain water quality parameters once the mine has flooded.

Upper Case predictions for sulfate, T-As and T-Sb in Brucejack Creek are presented, as these parameters are strongly influenced by the time to onset and severity of ML/ARD. Water quality time series plots are presented for these parameters below. Tabulated results for all parameters (as monthly maxima by mine phase) are provided in Appendix 3-2.

4.3.2.1 Sulfate

Upper Case predictions of sulfate at BJ 2.62 in Brucejack Creek exceed the BC FWAL 30-day guideline (128 mg/L) on a seasonal basis for both scenarios at the beginning of the Closure phase (Figure 4-39). Upper Case concentrations of sulfate are predicted to progressively decrease through Closure and approach the predicted Base Case concentration ranges Post-closure.

Figure 4-39: Upper Case sulfate concentration predictions at BJ 2.62 through Closure and Post-closure mine phases.

4.3.2.2 Arsenic

Upper Case predictions for T-As at BJ 2.62 in Brucejack Creek show strong seasonal fluctuations and generally exceed the BC FWAL maximum guideline (0.005 mg/L) through Closure and Post-closure for both scenarios (Figure 4-40). The concentration profile for Upper Case predictions mirrors the concentration profile for Base Case, but at concentrations nearly twice that predicted for Base Case.

Figure 4-40: Upper Case total arsenic concentration predictions at BJ 2.62 through Closure and Post-closure mine phases.

4.3.2.3 Antimony

Upper Case concentrations of T-Sb at BJ 2.62 in Brucejack Creek are predicted to exceed the BC FWAL 30-day guideline (0.009 mg/L) throughout most of the Closure phase for both scenarios (Figure 4-41). Upper Case predictions show a progressive decrease from ~0.026 mg/L to below the guideline at the end of the Closure phase and return to background levels (~0.00050 mg/L) during the Post-closure period.

Figure 4-41: Upper Case total antimony concentration predictions at BJ 2.62 through Closure and Post-closure mine phases. Note that the current Upper Case profiles overlap.

5. Effects Assessment

PRETIVM

5. Effects Assessment

5.1 Residual Effects Assessment

5.1.1 Risk Assessment Process

Potential risks to water quality from the proposed mining rate are initially assessed by identifying parameters of potential concern (Section 5.1.2). These are parameters that the Base Case water quality model predicts will have a higher concentration than has previously been assessed for any phase of mine life. Potential effects to receptors (Figure 5-1) are then assessed for each parameter of potential concern (POPC). The primary assessment endpoint is the potential for chronic toxicity to occur through exposure to a POPC.

Human health (Section 5.3) is assessed, although humans will not be exposed to mine effluent through drinking water. Aquatic life that may be exposed to contaminants are described in the Ecological Context section of the effects assessment. Terrestrial wildlife may be exposed to POPCs by using Brucejack Creek as drinking water. Exposure of terrestrial wildlife to POPCs in Brucejack Creek will be infrequent due to it being a high elevation stream surrounded by glaciers, and due to the short growing season. In contrast, aquatic life in Brucejack Creek will experience continuous exposure to POPCs in effluent. BC water quality guidelines indicate that aquatic life is more sensitive than terrestrial wildlife to toxicity from most contaminants in water; therefore, potential effects to terrestrial wildlife are assessed only for POPCs that have the potential to cause significant effects to aquatic life. If the potential for significant effects to aquatic life is considered low or not significant, then it is assumed that potential effects to terrestrial wildlife are not significant.

Bioaccumulation is not considered in the effects assessment, because the aquatic life communities do not possess the potential for significant bioaccumulation to occur. The aquatic life community in the receiving environment is limited to primary producers (periphyton) and secondary producers (benthic invertebrates). There is negligible potential for transfer of contaminants in benthic invertebrate tissues to fish, because fish habitat is too far downstream from Brucejack Creek (approximately 20 km) for invertebrates from this stream to serve as food to fish.

Figure 5-1: Conceptual model of contaminant transport to receptors.

5.1.2 Parameters of Potential Concern

Parameters of potential concern (POPCs) that were evaluated in the 2015 MA-EMA Permits Application and subsequent amendment applications were nitrate, nitrite, total arsenic, total beryllium, total chromium, total copper, total and dissolved iron, total phosphorus, total silver, and total zinc. The residual effects assessments of these parameters concluded that the maximum predicted Base Case concentrations would not have a significant effect on aquatic life (NO_2, NO_3, T-As, T-Be, T-Cr, T-Cu, T-Ag, T-Zn) or would have an effect of low significance (D-Fe, T-Fe, P-T).

The updated Base Case model for the production increase application predicts that the concentration of most parameters will be less than the concentrations evaluated previously, except for ammonia, antimony, arsenic, iron, and zinc. Other parameters have maximum modelled concentrations that are less than BC FWAL guidelines (Table 4-1). Ammonia, antimony, arsenic, iron, and zinc are the parameters in the updated model with Base Case predicted concentrations that are greater than previously assessed and that are greater at some stage of mine life than either the effluent discharge limit in PE-107835 or the BC

FWAL guideline (Table 5-1 and Table 5-2). These parameters will be assessed for potential residual effects and, as applicable, cumulative effects.

Table 5-1:
Maximum Concentrations from the BJ 3.10 Base Case Water Quality Model for All Mine Phases, Compared to the Maximum from the 2015 MA-EMA Permits Application, BC Water Quality Guidelines, and Effluent Discharge Limits

		Maximum Modelled		BC FWAL Guidelines		Effluent Discharge Limit
Parameter	**Units**	**2017 3800 tpd Application**	**2015 MA-EMA**	**Long-term**	**Short-term**	
Ammonia	mg/L	**2.8**	0.48	1.1	5.7	1.0
Antimony-T	µg/L	**13**	**10**	9	NP	NP
Arsenic-T	µg/L	***7***	***6***	NP	5	5

Notes: BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Ammonia guideline applies to pH 8.0 and 15 °C.
Concentrations that exceed long-term guidelines are shown in **bold** font.
Concentrations that exceed short-term guidelines are shown as ***bold italic underlined*** font.
NP=none proposed.

Table 5-2:
Maximum Concentrations from the BJ 2.62 Base Case Water Quality Model, for Closure and Post-closure Project Phases, Compared to the Maximum from the MA-EMA Permits Application, BC Water Quality Guidelines, and Effluent Discharge Limits

		Maximum Modelled		BC FWAL Guidelines		Effluent Discharge Limit
Parameter	**Units**	**2017 3800 tpd Application**	**2015 MA-EMA**	**Long-term**	**Short-term**	
Ammonia	mg/L	**2.8**	0.44	1.1	5.7	1.0
Antimony-T	µg/L	**14**	2	9	NP	NP
Arsenic-T	µg/L	***13***	***12***	NP	5	5

Iron-T	mg/L	***3.34***	***2.80***	NP	1.00	1.7
Zinc-T	µg/L	**8.6**	**8.5**	7.5	33	7.5

Notes: BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Ammonia guideline applies to pH 8.0 and 15 °C.
Concentrations that exceed long-term guidelines are shown in **bold** font.
Concentrations that exceed short-term guidelines are shown as ***bold italic underlined*** font.
Zinc guidelines calculated assuming a median baseline hardness of 28 mg/L as $CaCO_3$.
NP=none proposed.

5.1.3 Method of Characterizing Residual Effects

Potential residual effects of predicted water quality on the aquatic community in Brucejack Creek were assessed using the following criteria:

- **Geographic Extent**: the spatial scale over which the residual effect is expected to occur;

- **Ecological Context**: the ecological value or unique attributes of the aquatic community;
- **Toxicity**: characterization of potential toxic effects to the aquatic community;
- **Magnitude**: the expected magnitude or severity of the residual effect;
- **Duration**: the length of time the effect lasts;
- **Frequency**: how often the effect occurs;
- **Reversibility**: the degree to which effects to water quality can be mitigated or reversed; and
- **Resiliency**: the capacity of the aquatic community to recover from major changes in structure and function following disturbances.

A determination of significance was assigned for each POPC based on the characterization of these criteria. An assessment of the likelihood that a significant effect to aquatic life will occur was made, as well as a rating of the confidence in the assessment. These are described in the following subsections for each POPC. Monitoring sites in the receiving environment that are relevant to the effects assessment are presented in Figure 5-2.

5.1.4 Geographic Extent

The geographic extent of potential effects is defined by the area which is predicted to have a POPC concentration that is above a BC FWAL guideline, using the following classification:

- **Local:** predicted concentration is above the BW FWAL guideline in Brucejack Creek only;
- **Landscape:** predicted concentration is above the BW FWAL guideline in Sulphurets Creek at site SC0 (Figure 5-2); and
- **Regional:** predicted concentration is above the BW FWAL guideline at the mouth of Sulphurets Creek at site SC3 (Figure 5-2).

There is little dilution between the headwaters of Brucejack Creek and the confluence with Sulphurets Creek under the Sulphurets Glacier; therefore, it can be assumed that a predicted POPC concentration that is above the current discharge limit at BJ 3.10 will be above the limit throughout the 3 km length of Brucejack Creek.

TITLE: Receiving Environment Water Quality Monitoring Sites

PROJECT #: A406-5

FIGURE: 5-2

P:\@Drafting\Brucejack\Drafting Figures\MXD\Figure_5-1_Receiving Environment Monitoring Sites_20171211.mxd

The amount of mixing with Sulphurets Creek water that will be required to lower the concentration of a POPC to equal the BC FWAL guideline can be calculated using the following mass balance equation:

$$V_2 = \frac{C_1 V_1 - C_f V_1}{C_f - C_2}$$

where: C_1 = concentration at BJ 3.10
C_2 = background concentration
C_f = final concentration, set to the BC FWAL guideline
V_1 = discharge at BJ 3.10 (set to 1)
V_2 = discharge at SC0

The mixing requirement to produce a concentration that is equal to the BC FWAL guideline can be compared to estimates of mixing of Brucejack Lake effluent that occur at various locations in Sulphurets Creek (Figure 5-3). The proportion of Brucejack Lake effluent that makes up the total flow varies seasonally. Highest dilution occurs in summer months (July through October). Lower dilution is estimated during the rest of the year (November through June). This seasonality in mixing ratios will be taken into account when evaluating geographic extent of an effect on water quality. Monthly predictions of concentrations of POPCs were typically highest during low flow months (October through April) than during high flow months (May through September). Thus, highest annual predictions occur during lowest annual potential dilution in Sulphurets Creek. Therefore, geographic extent will be evaluated separately for high flow months and low flow months.

At the site SC0, just below the Sulphurets Glacier and the confluence with Brucejack Creek, the minimum ratio of 6:1 (6 parts background Sulphurets Creek water to 1 part Brucejack Lake effluent) occurs in December (Figure 5-3). Therefore, if the dilution required to meet the BC FWAL guideline for a POPC is <6:1, the geographic extent for the effects assessment is considered **local**. If the required dilution is >6:1, then the seasonality of the predicted concentration for a given POPC will be evaluated to determine if the geographic extent is **landscape** or **regional**.

Figure 5-3: Streamflow discharge ratios at nodes along Sulphurets Creek relative to discharge at BJ 3.10. Figure is copied from Plate 1 in ERM's Hydrology memo included as Appendix 4.

5.1.5 Ecological Context

The ecological context of the receiving environment is the same for all POPCs. Brucejack Creek and most of Sulphurets Creek are non-fish-bearing streams. In Sulphurets Creek, the upper limit of fish distribution is defined by a fish barrier approximately 1.3 km upstream of the Unuk River confluence (Figure 5-2). Overall, the distance between the outlet of Brucejack Lake and fish habitat is approximately 20 km. No amphibians have been noted during ecological surveys of these streams. Aquatic life in these non-fish-bearing water courses is therefore limited to benthic invertebrates and periphyton.

Baseline surveys in 2014 and 2015, and Operations phase surveys in 2016 and 2017, of benthic invertebrate communities in Brucejack Creek show that the assemblage is composed predominantly of chironomids (midges) and annelids (oligochaete worms) (Figure 5-4). Other taxa were rarely captured. The highest relative percentage of other taxa was 9% Ephemeroptera (mayflies) at BJ 0.27 in 2015, although it should be noted that total abundance of invertebrates at that station was low compared to other stations surveyed that year. Only chironomids were found at SC0, in both the 2014 and 2015 surveys. Stoneflies were present at SC0 in 2016 and 2017, but total abundance of invertebrates at

SC0 was very low compared to Brucejack Creek sites. The Brucejack and Sulphurets communities differed markedly from the reference creek (site L3 OF) which had a high proportion of mayflies and stoneflies.

Figure 5-4: Benthic invertebrate community composition by major taxon for Brucejack Creek, upper Sulphurets Creek, & reference lake L3 outfall.

Periphyton surveys in Brucejack Creek have found algal slimes on rocks composed of chlorophytes and diatom species. Macroalgae were not present.

Based on the biological monitoring data for Brucejack Creek and Sulphurets Creek, the ecological context of the receiving environment is considered **low**. There are no fish present for 20 km from the effluent discharge point. Brucejack Creek benthic invertebrate community does not represent a food source to fish at the mouth of Sulphurets Creek. The benthic invertebrate communities include a low number of taxa, almost entirely chironomids and annelids. These taxa are common throughout the province.

5.1.6 Ammonia

5.1.6.1 Introduction

The ammonia concentration in Brucejack Creek is predicted to increase during the Operations phase of mining, then decrease during Closure and Post-closure (Figure 4-4). The Base Case model predicts ammonia will increase to a maximum of 2.8 mg-N/L (Table 5-1) during Operations. The Upper Case model predicts a maximum of 4.0 mg-N/L (Figure 4-22). Pretivm is requesting that PE-107835 be amended to change the ammonia

discharge limit at BJ 3.10 from 1 to 4 mg-N/L. Therefore, the potential effect to aquatic life of discharging effluent with an ammonia concentration of 4 mg-N/L is assessed below.

5.1.6.2 Geographic Extent

The mixing ratio to lower the concentration of ammonia from 4 mg-N/L in Brucejack Creek to 0.88 mg-N/L at SC0 is 3.5:1, in both high flow and low flow months (Table 5-3). A final concentration of 0.88 mg-N/L is used because that value is a minimum BC FWAL guideline for ammonia at SC0, calculated from a pH of 8.1 and temperature of 12 °C. A pH of 8.1 is the 95th percentile baseline pH at SC0 and 12 °C is a maximum temperature at SC0. Baseline ammonia concentration at site SC0 was 0.0025 mg-N/L during high flow months, and 0.0065 mg-N/L during low flow months. Since the discharge ratio at SC0 is 6:1 or higher at all time of the year (Figure 5-3); the ammonia concentration in the entire length of Sulphurets Creek will be less than the BC FWAL guideline.

Table 5-3:
Mixing Required to Equal the Ammonia BC Water Quality Guidelines in Sulphurets Creek

Parameter	Flow[1]	C1 [BJ 3.10 (mg-N/L)]	C2 [SC0 (mg-N/L)]	Cf [WQG[2] (mg-N/L)]	V2:V1 Required Mixing
Ammonia	High	4	0.0025	1	3.5 : 1
	Low	4	0.0065	1	3.5 : 1

Notes: 1. High flow months are May through September, low flow October through April.
2. BC working water quality guideline for protection of freshwater aquatic life.

Because mixing of Brucejack Creek water with background water under the Sulphurets Glacier is calculated to reduce the ammonia concentration to less that the BC FWAL guidelines at all times of the year, the geographic extent of potential residual effects is classified as **local**.

5.1.6.3 Toxicity

The BC FWAL guidelines for ammonia (Nordin and Pommen, 2001) were not revised as part of the 2009 update of BC nitrogen guidelines, but it was noted in the overview report that the US EPA was planning an update, and that the BC guidelines would be re-evaluated based on new scientific literature included in the updated US EPA guideline. The US EPA published the updated ammonia guideline in 2013 (USEPA, 2013). The update included new toxicity data showing that freshwater molluscs (mussels and snails) were the most sensitive taxa to ammonia toxicity.

The chronic toxicity data compiled as part the US EPA ammonia guideline derivation show that molluscs (mussels and snails) were the most sensitive taxon to ammonia chronic

toxicity, followed by fish, crustaceans, and insects (Table 5-4). The data available regarding the toxicity of ammonia to freshwater phytoplankton and vascular plants indicate that aquatic plants appear to be two orders of magnitude less sensitive than the aquatic animals tested; therefore, it is assumed that any ammonia criterion appropriate for the protection of freshwater aquatic animals will also be protective of aquatic vegetation (USEPA, 2013).

There were no annelid chronic toxicity data, but annelids were included in the compilation of acute toxicity data (Table 5-5). The ranked acute toxicity data in USEPA (2013) show that molluscs were also the most sensitive taxon to acute toxicity, followed by fish, amphibians, crustaceans, insects, then annelids.

USEPA (2013) derived an acute-to-chronic ratio (ACR) of 6.32 for invertebrates. An ACR is a tool that provides a general idea how sensitive a species is to chronic toxicity, based on the measured acute toxicity data for that species. The value derived from an ACR is not a direct measure of chronic toxicity. Using the ACR to convert acute data to chronic data, the most sensitive species of invertebrate or annelid, which are the taxa found in Brucejack Creek, was the damselfly *Enallagma* sp. (Table 5-5).

Looking at the details of the studies of the most sensitive insects to ammonia toxicity (Table 5-6) shows that the pH at which the tests were conducted (7.7 – 8.0) are close to the pH measured at BJ 3.10 in 2017 (median = 7.8, 95th percentile = 7.9). There were two endpoints for the most sensitive species in chronic toxicity tests, the damselfly *Pteronarcella badia*, which were used to calculate the species mean chronic value of 73.74 mg-N/L (Table 5-4), which were quite different. The lower endpoint was 21.66 mg-N/L (Table 5-6). After converting acute to chronic data, there are two insects with more sensitive endpoints, 14.7 mg-N/L for the damselfly *Enallagma* sp. and 17.1 mg-N/L for the mayfly *Callibaetis* sp. (Table 5-6).

Overall, the toxicity of ammonia to aquatic life is one of the most comprehensively studied of all contaminants. Review of the compiled toxicity dataset for ammonia shows that the benthic invertebrate community in Brucejack Creek, which is comprised of insects and annelid worms, are relatively insensitive to chronic toxicity from ammonia. A discharge of 4 mg-N/L ammonia from BJ 3.10 is 3.7 to 5.4 times lower than the most sensitive chronic endpoints in the literature for invertebrates representative of the Brucejack Creek community. Periphyton are also present in Brucejack Creek, but are much less sensitive to toxicity from ammonia than invertebrates. Therefore, a discharge limit of 4 mg-N/L is considered **unlikely** to cause toxicity to aquatic life in the receiving environment.

Table 5-4:
Ranked Ammonia Chronic Toxicity Endpoints

Rank	Taxon	Common Name	Species	SMCV[1] (mg-N/L)
1	Mollusc	Wavy-rayed lamp mussel	*Lampsilis fasciola*	1.408
2	Mollusc	Fatmucket	*Lampsilis siliquoidea*	3.211
3	Fish	Bluegill	*Lepomis macrochirus*	3.273

Mayfly	*Callibaetis* sp.	4 d	7.81	11.9	*17.1*	107.8	Thurston *et al*. 1984

5.1.6.4 Magnitude, Duration, Frequency, Reversibility, and Resiliency

The magnitude of potential effects to aquatic life from an ammonia discharge limit of 4 mg-N/L is **low**, since toxicity to aquatic life in Brucejack Creek is unlikely.

The duration of potential effects to aquatic life is **long-term** since ammonia levels are predicted to be up to 4 mg-N/L throughout the 14 year Operations phase of the mine.

The frequency of potential effects to aquatic life is **constant**, since ammonia level is predicted to be elevated throughout the year.

The concentration of ammonia is predicted to decrease to below the BC FWAL guideline during the Closure phase of the mine; therefore, the effect on water quality is **reversible**.

No fish are present in Brucejack Creek. The aquatic community consists of periphyton and benthic invertebrates. The resiliency of these aquatic communities is considered **high**.

5.1.6.5 Significance of Potential Effects

Potential effects to aquatic life from effluent with ammonia concentration of 4 mg-N/L is considered **not significant** (Table 5-7). This discharge limit will not cause ammonia levels to be greater than the BC FWAL guideline in Sulphurets Creek. The low ecological context of potential effects to aquatic communities in Brucejack Creek and the unlikelihood of toxicity to aquatic life in Brucejack Creek support the conclusion that the potential for adverse effects is not significant.

Table 5-7:
Residual Effects Criteria Ratings for an Ammonia Discharge Limit of 4 mg-N/L

Criterion	Rating	Comment
Geographic extent	Local	Restricted to Brucejack Creek.
Ecological context	Low	No effects predicted to fish, fish habitat, or uncommon species.
Magnitude	Low	No toxicity is expected to any species in Brucejack Ck.
Duration	Long-term	Ammonia predictions are above the BC FWAL guideline for multiple years during Operations phase.
Frequency	Constant	Predicted concentrations are relatively constant throughout the year.
Reversibility	Reversible	Ammonia levels are predicted to decrease to less than the BC FWAL guideline during Closure phase.
Resiliency	High	The benthic invertebrates in Brucejack Lake are common throughout British Columbia
Likelihood	Low	Adverse effects to aquatic life are unlikely.
Significance	Not significant	The unlikelihood that ammonia concentration of 4 mg-N/L would cause toxicity, combined with the low ecological context and favourable ratings for other criteria indicate that the potential for adverse effects is not significant.
Confidence	High	The literature on chronic toxicity of ammonia to aquatic life is comprehensive and includes species representative of aquatic life present in Brucejack Creek during baseline monitoring.

5.1.7 Antimony

5.1.7.1 Introduction

The antimony concentration in Brucejack Creek is predicted to increase during the Operations phase of mining, and then decrease during Closure and Post-closure (Figure 4-14). The Base Case model predicts T-Sb will increase to a maximum of 14 µg/L (Table 5-2) during Operations. This is above the BC FWAL guideline of 9 µg/L. Effluent permit 107835 does not have a discharge limit for T-Sb. In anticipation that T-Sb levels at BJ 3.10 may rise above the BC FWAL guideline, Pretivm is requesting that PE-107835 be amended to add a T-Sb discharge limit. The limit requested is the maximum Upper Case model prediction at BJ 3.10 of 28 µg/L (Figure 4-26). Therefore, the effects assessment will focus on the potential for the Upper Case prediction to cause adverse effects.

5.1.7.2 Geographic Extent

The mixing ratio to lower the concentration of T-Sb from 28 µg/L in Brucejack Creek to equal the BC FWAL working guideline of 9 µg/L at SC0 is 3.3:1 during high flow months and 2.6:1 during low flow months (Table 5-8). Baseline T-Sb concentration at site SC0

was 3.2 µg/L during high flow months, and 1.6 µg/L during low flow months. Since the discharge ratio at SC0 is 6:1 or higher at all times of the year (Figure 5-3), the T-Sb concentration in the entire length of Sulphurets Creek will be less than the BC FWAL working guideline.

Table 5-8:
Mixing Required to Equal BC Water Quality Guidelines in Sulphurets Creek

Parameter	Flow[1]	C1 [BJ 3.10 (µg/L)]	C2 [SC0 (µg/L)]	Cf [WQG[2] (µg/L)]	V2:V1 Required Mixing
Total Antimony	**High**	**28**	**3.2**	**9**	**3.3:1**
	Low	**28**	**1.6**	**9**	**2.6:1**

Notes: 1. High flow months are May through September, low flow October through April.
2. BC working water quality guideline for protection of freshwater aquatic life.

Because mixing of Brucejack Creek water with background water under the Sulphurets Glacier is calculated to reduce the T-Sb concentration to <9 µg/L at all times of the year, the geographic extent of potential residual effects is classified as **local**.

5.1.7.3 Toxicity

The BC FWAL working guideline for T-Sb was adopted from the Australia and New Zealand guideline document (ANZECC, 2000) which states:

> *A freshwater low reliability trigger value of 9 µg/L was derived for antimony (III) from the fish figure using an AF of 1000. This figure should only be used as an indicative interim working level. Collection of more data would assist in revision of this figure.*

That is, the guideline of 9 µg/L was derived by applying a safety factor of 1000 to an acute toxicity endpoint (LC50) of 9000 µg/L for the fish *Pimephales promelas* (fathead minnow).

A literature search of antimony toxicity studies found that the lowest toxicity endpoint is a median growth inhibition (EC50) of the alga *Selenastrum capricornutum* of 740 µg/L (Appendix 5). This algal test can be considered representative of potential toxicity to periphyton in Brucejack Creek and it indicates that toxicity to aquatic life in Brucejack Creek from exposure to 28 µg/L T-Sb is **unlikely**.

5.1.7.4 Magnitude, Duration, Frequency, Reversibility, and Resiliency

The magnitude of potential effects to aquatic life from a T-Sb discharge limit of 28 µg/L is **low**, since toxicity to aquatic life in Brucejack Creek is unlikely.

The duration of potential effects to aquatic life is **long-term** since T-Sb levels are predicted to increase throughout the 14-year Operations phase of the mine.

The frequency of potential effects to aquatic life is **constant**, since T-Sb level is predicted to be elevated throughout the year.

The concentration of T-Sb is predicted to decrease to below the BC FWAL guideline during the Closure phase of the mine; therefore, the effect on water quality is **reversible**.

No fish are present in Brucejack Creek. The aquatic community consists of periphyton and benthic invertebrates. The resiliency of these aquatic communities is considered **high**.

5.1.7.5 Significance of Potential Effects

Potential effects to aquatic life from effluent with 28 µg/L T-Sb is considered **not significant** (Table 5-9). This discharge limit will not cause T-Sb levels to be greater than the BC FWAL guideline in Sulphurets Creek. The low ecological context of potential effects to aquatic communities in Brucejack Creek and the unlikelihood of toxicity to aquatic life in Brucejack Creek support the conclusion that the potential for adverse effects is not significant.

Table 5-9:
Residual Effects Criteria Ratings for an Antimony Discharge Limit of 28 µg/L

Criterion	Rating	Comment
Geographic extent	Local	Restricted to Brucejack Creek.
Ecological context	Low	No effects predicted to fish, fish habitat, or uncommon species.
Magnitude	Low	No toxicity is expected to any species in Brucejack Ck.
Duration	Long-term	Antimony predictions are above the BC FWAL guideline for multiple years during Operations phase.
Frequency	Constant	Predicted concentrations are relatively constant throughout the year.
Reversibility	Reversible	Antimony levels are predicted to decrease to less than the BC FWAL guideline during Closure phase.
Resiliency	High	The benthic invertebrates in Brucejack Lake are common throughout British Columbia
Likelihood	Low	Adverse effects to aquatic life are unlikely.
Significance	Not significant	The unlikelihood that 28 µg/L T-Sb would cause toxicity, combined with the low ecological context and favourable ratings for other criteria indicate that the potential for adverse effects is not significant.
Confidence	Medium	The literature on chronic toxicity of antimony to aquatic life is limited, but does include species of algae and invertebrates.

5.1.8 Arsenic

5.1.8.1 Introduction

The production increase application Base Case model results for total arsenic (T-As) are slightly higher than the concentrations evaluated in the 2015 MA-EMA Permits Application. The maximum BJ 3.10 prediction increases from 6 µg/L to 7 µg/L (Table 5-1). The maximum BJ 2.62 prediction increases from 12 µg/L to 13 µg/L (Table 5-2). The BJ 3.10 predictions are that the current effluent discharge limit of 5 µg/L will be exceeded during Operations (Figure 4-11). The limit of 5 µg/L is equal to the BC FWAL guideline.

The model results are monthly average concentrations. It is expected that there will be variability in the results of weekly samples at BJ 3.10, resulting in some samples that are greater than the monthly average. For this reason, Pretivm is applying to increase the effluent discharge limit to 10 µg/L, which is equal to the maximum Upper Case model result for BJ 3.10 (Figure 4-25).

The water quality model predicts that the maximum T-As concentration of 13 µg/L will occur at BJ 2.62 during Closure, and the maximum Post-closure concentration at BJ 2.62 will be 11 µg/L (Figure 4-31). The residual effects assessment will evaluate the potential for adverse effects to aquatic communities in Brucejack Creek from exposure to 13 µg/L T-As, which is the maximum Base Case prediction at BJ 2.62.

5.1.8.2 Geographic Extent

The geographic extent of water with T-As levels above the BC FWAL guideline of 5 µg/L is calculated in the same way described for T-Sb (Section 5.1.7.2) and results are presented in Table 5-10. During high flow months, the baseline T-As concentration at Sulphurets Creek site SC0 is 17 µg/L; therefore, T-As levels at SC0 during high flow months are naturally elevated above the BC FWAL guideline of 5 µg/L and no mixing ratio would reduce concentrations to 5 µg/L. Further downstream of Sulphurets Lake in Sulphurets Creek, at site SC1, the baseline T-As concentration is 3.4 µg/L (Table 5-10). A mixing ratio of 5 parts SC1 water with 1 part Brucejack Creek water with 13 µg/L T-As is required to produce a concentration equal to 5 µg/L during high flow months. During low flow months, a mixing ratio of 2:1 will result in 5 µg/L in Sulphurets Creek at SC0 and SC1 (Table 5-10).

Table 5-10:
Mixing Required to Equal the BC Arsenic Water Quality Guideline in Sulphurets Creek

Location	Flow[1]	C1 [BJ 2.62 (µg/L)]	C2 [SC0 (µg/L)]	Cf [WQG[2] (µg/L)]	V2:V1 Required Mixing
SC0	High	13	17	5	not applicable
SC0	Low	13	1	5	2.1:1
SC1	High	13	3.4	5	5.1:1
SC1	Low	13	0.4	5	1.7:1

Notes: 1. High flow months are May through September, low flow October through April.
2. BC water quality guideline for protection of freshwater aquatic life.

The mixing ratio of Brucejack Creek water with Sulphurets Creek water varies seasonally, with a minimum of 6:1 in December (Figure 5-3). A mixing ratio of 6:1 or more will result in T-As concentrations in Sulphurets Creek that are <5 µg/L; therefore, only Brucejack Creek is modelled to have T-As above BC FWAL guideline, and the geographic extent of potential residual effects is classified as **local**.

5.1.8.3 Ecological Context

The ecological context of potential effects of predicted T-As levels is classified as **low**, because there are no fish in Brucejack Creek; Brucejack Creek is not fish habitat; and the benthic invertebrates present in the stream are common in British Columbia.

5.1.8.4 Toxicity

The BC FWAL guideline for T-As of 5 µg/L was derived from the lowest relevant toxicity endpoint of 50 µg/L (EC50 for growth of the green alga *Scenedesmus obliquus* (Vocke *et al.*, 1980) and a safety factor of 10. A literature search did not reveal any recent studies (after 2000) which found a species more sensitive to arsenic toxicity.

The BC arsenic guideline Overview Report also cites a toxicity test using the invertebrate *Daphnia magna* that had a Lowest Observed Effect Concentration (LOEC) of 38 µg/L for reproduction. This study was reviewed by the European Chemicals Agency and classified as not reliable. The U.S. ECOTOX database reports five other studies of growth or reproduction in *Daphna magna*, with reported endpoints ranging from 880 to 3,700 µg/L. The anomalously low endpoint cited in the BC Overview Report lends support to the conclusion that this study is not reliable.

Pretivm commissioned a site-specific toxicity test of BJ 3.10 water with added arsenic and antimony (Appendix 6). BJ 3.10 water was collected on October 30th, 2017 and shipped

to Nautilus Environmental in Burnaby, BC. Nautilus conducted a growth test using the green alga *Pseudokirchneriella subcapitata*, which is a taxon known to be sensitive to arsenic toxicity. The test solutions were spiked with both arsenic and antimony, in the ratio that had been observed in monitoring of water quality at BJ 3.10.

The EC50 for T-As in the BJ 3.10 test was 74.1 µg/L. The Lowest Observable Effect Concentration (LOEC) from the BJ 3.10 test was 18.7 µg/L. These results indicate that the predicted concentration of 13 µg/L T-As during Post-closure is **unlikely** to produce toxicity to aquatic life in Brucejack Creek.

5.1.8.5 Magnitude, Duration, Frequency, Reversibility, and Resiliency

The magnitude of potential effects to aquatic life from a T-As concentration of 13 µg/L is **low**, since toxicity to aquatic life in Brucejack Creek is unlikely.

The duration of potential effects to aquatic life is **permanent** since T-As levels greater that the BC FWAL guideline are predicted to occur during Post-closure.

The frequency of potential effects to aquatic life is **constant**, since T-As level is predicted to be elevated throughout the year.

The potential effect is classified as **irreversible**, since the T-As levels greater the BC FWAL guideline are predicted to occur during Post-closure.

No fish are present in Brucejack Creek. The aquatic community consists of periphyton and benthic invertebrates. The resiliency of these aquatic communities is considered **high**.

5.1.8.6 Significance of Potential Effects

Potential effects to aquatic life from exposure to 13 µg/L T-As is considered **not significant** (Table 5-11). The predicted T-As concentration is greater than the BC FWAL guideline only in Brucejack Creek. The low ecological context of potential effects to aquatic communities in Brucejack Creek and the unlikelihood of toxicity to aquatic life in Brucejack Creek support the conclusion that the potential for adverse effects is not significant.

Table 5-11:
Residual Effects Criteria Ratings for an Arsenic Concentration of 13 µg/L

Criterion	Rating	Comment
Geographic extent	Local	Restricted to Brucejack Creek.
Ecological context	Low	No effects predicted to fish, fish habitat, or uncommon species.
Magnitude	Low	No toxicity is expected to any species in Brucejack Creek.
Duration	Permanent	Arsenic predictions are above the BC FWAL guideline during Post-closure phase.
Frequency	Constant	Predicted concentrations are relatively constant throughout the year.
Reversibility	Irreversible	Arsenic predictions are above the BC FWAL guideline during Post-closure phase.
Resiliency	High	The benthic invertebrates in Brucejack Lake are common throughout British Columbia.
Likelihood	Low	Adverse effects to aquatic life are unlikely.
Significance	Not significant	The unlikelihood that 13 µg/L T-As would cause toxicity, combined with the low ecological context indicate that the potential for adverse effects is not significant.
Confidence	High	The effects assessment is supported by site-specific toxicity testing of species known to be sensitive to arsenic.

5.1.9 Iron

Iron is predicted to remain below BC FWAL guidelines during Operations phase, then to increase above the guidelines at BJ 2.62 as the underground floods and groundwater flows to Brucejack Creek during Closure and Post-closure (Figure 4-33). Because the source is groundwater, most of the iron is predicted to occur as dissolved iron (D-Fe). The updated Base Case iron predictions are about 17% higher than predictions reported in the 2105 MA-EMA Permits Application (Table 5-12).

Table 5-12:
Maximum Concentrations from the BJ 2.62 Base Case Water Quality Model Compared to the Maximum from the 2015 MA-EMA Permits Application and BC Water Quality Guidelines

		Maximum Modelled		BC FWAL Guidelines	
Parameter	**Units**	**2017 3800 tpd application**	**MA-EMA**	**Long-term**	**Short-term**
Iron-D	mg/L	***3.13***	***2.67***	NP	0.35
Iron-T	mg/L	***3.34***	***2.80***	NP	1.00

Notes: BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Concentrations that exceed short-term guidelines are shown as ***bold italic underlined*** font.
NP=none proposed.

The water quality model assumes that there is no attenuation of metals along flow paths or in the receiving environment. This conservative approach to water quality prediction can result in unrealistic concentrations, particularly for pH sensitive metals which are subject to thermodynamic solubility controls, such as iron.

The Closure and Post-closure underground water source term in the water quality model assumes that iron will exist in solution in the ferrous (Fe^{2+}) oxidation state. Once these groundwater flow paths daylight and interact with atmospheric oxygen, Fe^{2+} iron will rapidly be oxidized to ferric iron (Fe^{3+}) which is relatively insoluble under neutral pH conditions. Iron oxidation will result in the formation of Fe-oxyhydroxides.

In order to predict Fe solubility in Brucejack Creek, a PHREEQC solubility model was constructed using the minteq.v4 database (Parkhurst and Apello, 1999). The solubility of ferrihydrite [$Fe(OH)_3$] and goethite [α-FeO(OH)] was calculated using a solution containing the highest predicted concentrations for Brucejack Creek in the Post closure scenario. The solution was assumed to be in equilibrium with atmospheric oxygen. The solubility of these phases is highly sensitive to pH (Figure 5-5). Median pH of Brucejack Creek at BJ 3.10 is 7.8, which is at the lower end of the range of iron solubility. The PHREEQC model results show that Fe solubility between a pH of 6.0 and 8.0 ferrihydrite precipitation can be expected to reduce dissolved Fe concentrations to between 0.026 mg/L to 0.0003 mg/L. With time, ferrihydrite will convert to goethite which is considerably less soluble.

Figure 5-5: Modelled solubility of expected forms of iron in flowing to Brucejack Creek along groundwater flow paths.

Since redox reactions are expected to result in iron concentrations below BC FWAL guidelines, no significant effects to aquatic life are expected. Precipitation of Fe-oxyhydroxides would increase the sediment iron concentration in Brucejack Creek, but it is not possible to predict the final sediment Fe concentration. Increased iron levels in sediment could cause toxicity to sensitive benthic organisms in Brucejack Creek. The geographic extent of elevated sediment Fe levels is expected to be local. Sediment export from Brucejack Creek is small relative to the sediment loading that comes from Sulphurets Glacier. This is evidenced by total suspended solids (TSS) measurements made as part of the receiving environment monitoring program, which are routinely <3 mg/L (detection limit) in Brucejack Creek and >100 mg/L at SC0 in Sulphurets Creek below the glacier. There is no potential to increase the iron levels in lower Sulphurets Creek, which receives high iron loadings from Mitchel Creek.

Since water is expected to have Fe concentrations below BC FWAL guidelines, there is no significant effect expected to aquatic life. Sediment iron levels may increase and may have a localized effect on benthic organisms. The overall significance of iron predictions is considered low (Table 5-13).

Table 5-13:
Residual Effects Criteria Ratings for Iron

Criterion	Rating	Comment
Geographic extent	Local	Restricted to Brucejack Creek.
Ecological context	Low	No effects predicted to fish, fish habitat, or uncommon species.
Magnitude	Moderate	There may be toxicity to sensitive benthic organisms from precipitated iron.
Duration	Permanent	Iron is predicted to increase during Post-closure phase.
Frequency	Constant	Predicted iron is from groundwater, which will flow all year.
Reversibility	Irreversible	Iron in water in contact with the flooded underground mine will continue to have iron during Post-closure.
Resiliency	High	The benthic invertebrates in Brucejack Lake are common throughout British Columbia.
Likelihood	Moderate	Increased sediment iron levels are expected.
Significance	Low	There is potential for localized effects to benthic organisms from precipitation of iron.
Confidence	High	The slow significance rating is based on the low ecological context of the waterbody which may receive increased sediment iron levels, and the high iron levels that are present in fish habitat in lower Sulphurets Creek.

5.1.10 Zinc

Base Case predictions for total zinc (Zn-T) are that it will remain below the discharge limit at BJ 3.10 of 7.5 µg/L during all phases of the mine (Figure 4-20), which is equal to the BC FWAL guideline. The maximum prediction at BJ 2.62 is 8.6 µg/L (Table 5-2), which is slightly above the guideline. This prediction is essentially the same as for the 2015 MA-EMA Permits Application, which had a maximum of 8.5 µg/L. Since the update model has the same predictions as was evaluated in the 2015 MA-EMA Permits Application, the residual effects assessment does not change from what was presented in that application. It concluded that a Science Based Environmental Benchmark of 60 µg/L is appropriate for Brucejack Creek. Since the predicted maximum Zn-T concentration of 8.6 µg/L is well below this benchmark, no significant adverse effect to aquatic life from Zn-T is expected.

5.2 Cumulative Effects Assessment

5.2.1 Cumulative Concentration Calculations

Cumulative environmental effects are changes to the environment caused by the combined effect of past, present and reasonably foreseeable future activities. Construction of the Kerr-Sulphurets-Mitchell (KSM) mine is a potential future activity that would affect water quality in the Brucejack Mine receiving environment. An Environmental Assessment Certificate was issued in July 2014 to Seabridge Gold Inc. for the KSM project. The project description for KSM is for a 5-year Construction phase, 51.5-year Operation phase, 3-year Closure phase, and Post-closure. A water quality effects assessment was conducted for KSM which included predictions of water quality in Sulphurets Creek downstream of mine facilities, at site SC3 (Figure 5-2).

The Brucejack residual effects assessment (Section 5.1) identified ammonia, antimony and arsenic as parameters which are expected to have concentrations at the mouth of Brucejack Creek that are greater than BC FWAL guidelines. An effluent discharge limit of 4 mg-N/L ammonia, 28 µg/L T-Sb and 10 µg/L T-As is being applied for by Pretivm. Ammonia and antimony levels are expected to decrease during Closure and Post-closure, while the maximum T-As concentration expected in Brucejack Creek (13 µg/L) will occur during low-flow months of Post-closure. Thus, ammonia and antimony from Brucejack Gold Mine effluent have the potential to cause cumulative changes to water quality at Sulphurets Creek site SC3 during Construction and Operation phases of the KSM project. Arsenic from Brucejack Gold Mine has the potential to cause cumulative changes to water quality at SC3 during all of the KSM mine phases.

Cumulative effects to water quality at SC3 were calculated using the mass balance equation:

$$C_f = \frac{C_1V_1 + C_2V_2}{V_1 + V_2}$$

where: C_f = final concentration
C_1 = concentration at BJ 3.10
C_2 = predicted concentration at SC3 for the KSM mine
V_1 = discharge at BJ 3.10
V_2 = discharge at SC3

This is the same mass balance equation that was used for calculating residual effects to water quality in Brucejack Creek and Sulphurets Creek (Section 5.1).

For the cumulative effects assessment, it was assumed that concentration of ammonia is 4 mg-N/L during low and high flow months, T-Sb is 28 µg/L during low and high flow months, and T-As is 13 µg/L during low flow months and 10 µg/L during high flow months. These concentrations were used for variable C_1 in the mass balance equation.

Water quality predictions for the KSM project were presented in Chapter 14 of the KSM Application/EIS (Rescan, 2013), which was posted on the BC Environmental Assessment Office website. Expected Case predictions were presented as summary statistics (minimum, mean, median, and maximum) from monthly predictions in each project phase (Table 5-14). The maximum ammonia prediction occurred during Operations phase. The maximum antimony prediction did not differ between project phases. The maximum arsenic prediction occurred during Construction and Operation phases (Table 5-14). Predictions from the Operations phase were used for variable C_2 in the mass balance equation, as an upper estimate of water quality from the KSM mine.

Table 5-14:
Predicted Concentrations of Ammonia, Antimony and Arsenic for the KSM Project

Parameter	Project Phase	Units	Min.	Mean	Median	Max
Ammonia	Construction	mg-N/L	0.0020	0.0990	0.0990	0.1910
	Operations	mg-N/L	0.0025	0.0334	0.0185	0.2337
	Closure	mg-N/L	0.0025	0.0035	0.0025	0.0082
	Post-closure	mg-N/L	0.0025	0.0033	0.0025	0.0082
Antimony-T	Construction	µg/L	0.4	0.7	0.6	1.2
	Operations	µg/L	0.4	0.7	0.6	1.2
	Closure	µg/L	0.4	0.7	0.6	1.2
	Post-closure	µg/L	0.4	0.7	0.6	1.2
Arsenic-T	Construction	µg/L	0.1	2.4	0.6	10.9
	Operations	µg/L	0.1	2.5	0.7	10.9
	Closure	µg/L	0.4	0.7	0.7	1.2
	Post-closure	µg/L	0.4	0.7	0.7	1.2

Notes: Data are extracted from Tables 14.7-27, through -30 of Rescan (2013).

Discharge ratios used in the residual effects assessment determination of geographical extent (Figure 5-3 and Appendix 4) do not extend far enough downstream on Sulphurets Creek to where cumulative effects to water quality may occur. Discharge ratios between sites BJ 3.10 and SC3 are available in Chapter 10 (Surface Water Hydrology Predictive Study) of the Brucejack Mine Application/EIS (Rescan, 2013). Discharge ratios were available for mean annual flows as well as peak flows, low flows, and 7-day low flows for return years ranging from Q2 to Q200 for peak flows and Q2 to Q20 for low flows (Table 5-15). Discharge ratios estimates were lowest during peak flow and highest during low flows. For the cumulative effects assessment, a mean annual discharge ratio of 34.6 and minimum ratio of 10.2 (peak flow, Q200) were used for the V_1:V_2 variables in the mass balance equation.

Table 5-15:
Estimated Discharge Ratio Between Sites BJ 3.10 and SC3

Condition	Location	Return Period							
		Q1	Q2	Q5	Q10	Q20	Q50	Q100	Q200
Mean Annual	BJ 3.10 (m^3/s)	0.65	-	-	-	-	-	-	-
	SC3 (m^3/s)	22.5	-	-	-	-	-	-	-
	ratio	**34.6**	-	-	-	-	-	-	-
Peak Flow	BJ 3.10 (m^3/s)	-	11	20	26	31	39	44	50
	SC3 (m^3/s)	-	146	223	276	329	399	453	508
	ratio	-	**13.3**	**11.2**	**10.6**	**10.6**	**10.2**	**10.3**	**10.2**
Annual 7-d Low Flow	BJ 3.10 (m^3/s)	-	0.05	0.03	0.02	0.02	-	-	-
	SC3 (m^3/s)	-	1.26	0.91	0.77	0.65	-	-	-
	ratio	-	**25.2**	**30.3**	**38.5**	**32.5**	-	-	-
Jun-Sep 7-d Low Flow	BJ 3.10 (m^3/s)	-	0.33	0.21	0.17	0.14	-	-	-
	SC3 (m^3/s)	-	10.31	7.43	6.27	5.48	-	-	-
	ratio	-	**31.2**	**35.4**	**36.9**	**39.1**	-	-	-

Notes: Data are extracted from Tables 10.3-5, -7, and -8, and -9 of Pretivm (2014).

Calculations of cumulative concentrations of ammonia at SC3 range from 0.13 to 0.34 mg-N/L (Table 5-16) during mean annual flows, and from 0.37 to 0.57 mg-N/L during 1 in 200 peak flows (Table 5-17). All estimates of cumulative ammonia concentration are below the BC FWAL guideline of 1.0 mg-N/L for a baseline pH of 8.0 at SC3 and a temperature of 16 °C.

Calculations of cumulative concentrations at T-Sb at SC3 range from 1.2 to 2.0 µg/L for mean annual flow and range from 2.9 to 3.6 µg/L for Q200 peak flow. All estimated T-Sb concentrations are less than the BC FWAL guideline of 9 µg/L.

Table 5-16:
Cumulative Predicted Concentrations of Ammonia, Antimony and Arsenic at Site SC3 for Mean Annual Flows

Parameter	Statistic	Units	C_1 (BJ 3.10) (µg/L)	C_2 (SC3) (µg/L)	V_1 (BJ 3.10)	V_2 (SC3)	C_f (final concentration)
Ammonia	min	mg-N/L	4	0.0025	1	34.6	**0.134**
	mean	mg-N/L	4	0.0334	1	34.6	**0.145**
	median	mg-N/L	4	0.0185	1	34.6	**0.130**
	max	mg-N/L	4	0.2337	1	34.6	**0.339**
Antimony-T	min	µg/L	28	0.4	1	34.6	**1.2**
	mean	µg/L	28	0.7	1	34.6	**1.5**
	median	µg/L	28	0.6	1	34.6	**1.4**
	max	µg/L	28	1.2	1	34.6	**2.0**
Arsenic-T	min	µg/L	13	0.1	1	34.6	**0.5**
	mean	µg/L	13	2.5	1	34.6	**2.8**
	median	µg/L	13	0.7	1	34.6	**1.0**
	max	µg/L	13	10.9	1	34.6	**11.0**

Table 5-17:
Cumulative Predicted Concentrations of Ammonia, Antimony and Arsenic at Site SC3 for Peak Flows

Parameter	Statistic	Units	C_1 (BJ 3.10)	C_2 (SC3)	V_1 (BJ 3.10)	V_2 (SC3)	C_f (final concentration)
Ammonia	min	mg-N/L	4	0.0025	1	10.2	**0.378**
	mean	mg-N/L	4	0.0334	1	10.2	**0.388**
	median	mg-N/L	4	0.0185	1	10.2	**0.374**
	max	mg-N/L	4	0.2337	1	10.2	**0.570**
Antimony-T	min	µg/L	28	0.4	1	10.2	**2.9**
	mean	µg/L	28	0.7	1	10.2	**3.1**
	median	µg/L	28	0.6	1	10.2	**3.0**
	max	µg/L	28	1.2	1	10.2	**3.6**
Arsenic-T	min	µg/L	10	0.1	1	10.2	**1.0**
	mean	µg/L	10	2.5	1	10.2	**3.2**
	median	µg/L	10	0.7	1	10.2	**1.5**
	max	µg/L	10	10.9	1	10.2	**10.8**

Calculations of cumulative concentrations at T-As at SC3 range from 0.5 to 10.0 µg/L for annual mean flow (Table 5-16) and range from 1.0 to 10.8 µg/L for peak flow (Table 5-17). Estimated T-As concentrations for minimum, mean, and median KSM predictions are less than the BC FWAL guideline of 5 µg/L. The maximum KSM prediction for T-As is 10.9 µg/L. This is likely the result of arsenic associated with high suspended solids

concentrations at SC3. Evidence of this is from baseline measurements at SC3 during high flow months (May through October), which had mean T-As of 11.0 µg/L and mean As-D of 0.2 µg/L (data from Table 14-1.1 of Rescan, 2013). Discharge of Brucejack Creek water with 13 µg/L T-As during mean annual flows would result in a change of maximum concentration at SC3 from 10.9 to 11.0 µg/L. During peak flows, the discharge of effluent with 10 µg/L T-As from Brucejack Gold Mine would change the maximum cumulative concentration at SC3 from 10.9 µg/L to 10.8 µg/L.

5.2.2 Cumulative Effects Ratings

The cumulative effects calculations indicate that the discharge of effluent from Brucejack Gold Mine with an ammonia concentration of 4 mg-N/L will not cause concentrations to go above the BC FWAL guideline of 1.0 mg-N/L in Sulphurets Creek under any of the scenarios assessed. Similarly, the discharge of effluent with 28 µg/L T-Sb will not cause concentrations to go above the BC FWAL guideline of 9 µg/L in Sulphurets Creek under any of the scenarios assessed. Therefore, no significant cumulative effect to water quality is expected from an ammonia discharge limit of 4 mg-N/L or a T-Sb discharge limit of 28 µg/L.

The cumulative effects calculations for T-As indicate that discharge of effluent with a proposed limit of 10 µg/L will not cause concentrations at SC3 to go above the BC FWAL guideline of 5 µg/L, except when levels at SC3 are naturally greater than 5 µg/L. Under that scenario, the discharge of effluent with 10 µg/L T-As will cause a negligible decrease (from 10.9 to 10.8 µg/L) to the maximum KSM prediction at SC3. Therefore, no significant cumulative effect to water quality is expected from a T-As discharge limit of 10 µg/L.

During Post-closure, when the model predicts that T-As predictions at BJ 2.62 will increase to 13 µg/L during low flow months, the cumulative concentration calculations at SC3 are less than the BC FWAL guideline of 5 µg/L, except when levels at SC3 are naturally greater than 5 µg/L. Under that scenario, the discharge of BJ 2.62 water with 13 µg/L T-As will cause a negligible increase (from 10.9 to 11.0 µg/L) to the maximum predictions at SC3. Therefore, no significant cumulative effect to water quality is expected from Post-closure predictions of 13 µg/L T-As at BJ 2.62.

5.3 Human Health Assessment

The proposed T-Sb discharge limit of 28 µg/L is above the Health Canada drinking water guideline of 6 µg/L. The proposed T-As discharge limit of 10 µg/L is equal to the Health Canada drinking water guideline. Health Canada currently does not recommend a drinking water guideline for ammonia (Health Canada, 2013). Health Canada drinking water

guidelines are designed to protect the health of the most vulnerable members of society, such as children and the elderly, from long-term exposure.

Since the proposed Sb discharge limit will cause Sb levels in Brucejack Creek to be greater than drinking water guideline, Brucejack Creek water should not be used as the drinking water source for the mine camp. Mine camp drinking water is currently taken from a potable water well, which will continue to be the source of drinking water for the camp during Operations and Closure phases.

The Assessment of Potential Health Effects carried out for the Application/EIS (Chapter 21 of Rescan, 2013) concluded that it is unlikely that people drink water from the Brucejack watershed. This conclusion was based on the inaccessibility of the watershed, the cold weather during winter, absence of country foods such as fish in the area, and general low use of the Brucejack watershed by individuals from First Nations groups or the general public (Appendix 21-A of Chapter 21 of the Application/EIS; Rescan, 2013). There was no indication of Skii km Lax Ha or other First Nations obtaining drinking water from the Mine Site Area.

Effluent with the proposed discharge limits for ammonia, Sb, and As is predicted to result in little or no increase to the concentrations of these parameters in Sulphurets Creek where fish are present. The predicted cumulative effects concentrations (Table 5-16) are less than the BC water quality guidelines for the protection of freshwater aquatic life. The low predicted concentrations in Sulphurets Creek, as well as the low abundance of fish in baseline surveys of lower Sulphurets Creek (Appendix 15-A of Rescan, 2013), and the low expectation that fish will be captured from Sulphurets Creek for eating, provide lines of evidence that no significant effect to human health is expected from the proposed effluent discharge limits.

6. Summary

6. Summary

The Brucejack Gold Mine water quality model has been updated with revised mine schedules and updated source terms to reflect water quality predictions for the proposed ore production rate increase. Additional revisions to the water quality model have been carried out based on new geochemical data sets, an updated water balance, operational data acquired through the various monitoring programs and changes to water management plans.

Separate model updates were completed for the two mine waste management scenarios considered in this application (*i.e.*, Scenario 1, where all waste rock is placed in Brucejack Lake; and Scenario 2, where a portion of waste rock is backfilled in the underground mine). Base Case and Upper Case water quality predictions for each scenario were modelled and are presented for two stations: BJ 3.10, the mine's regulated discharge point, located at the outlet of Brucejack Lake; and BJ 2.62, a downstream monitoring location in Brucejack Creek.

The water quality model results and the associated effects assessment are summarized as follows:

- Base Case BJ 3.10 water quality predictions for ammonia, nitrite, nitrate, D-Al, T-Sb, T-As, D-Fe, T-Li and T-Se are higher than predicted in the 2015 MA-EMA Permits Application model; however, maximum Base Case predictions for nitrite, nitrate, D-Al, D-Fe, T-Li and T-Se are below PE-107835 discharge limits or BC FWAL guidelines.
- Base Case BJ 2.62 water quality predictions are higher than predictions in the 2015 MA-EMA Permits Application for ammonia, nitrite, nitrate, Cl, F, D-Al, T-Sb, T-As, D-Fe, T-Fe, T-Li, T-Se, T-U and T-Zn; however, only T-Sb, T-As, T-Fe, D-Fe and T-Zn exceed PE-107835 discharge limits or applicable BC FWAL guidelines.
- In general, water quality predictions for Scenario 1 are similar to Scenario 2, indicating that placement of waste rock in the lake or placement underground will have little influence on the water quality in the receiving environment.
- Based on predicted water quality for Operation, Closure and Post-Closure phases, ammonia, Sb, As, Fe and Zn were identified as parameters of potential concern. These parameters were assessed for potential residual and cumulative effects.
- The Maximum Base Case prediction for ammonia (2.8 mg-N/L) occurs during the Operations phase at BJ 3.10 and is higher than previously predicted values due to revisions applied to ammonia source terms which conservatively assume low

nitrification rates. The predicted value is above the PE-107835 discharge limit of 1.0 mg/L. Base Case ammonia concentrations at both BJ 3.10 and BJ 2.62 are predicted to decrease to background levels by the end of the Closure phase. The predicted concentrations are less than the lowest chronic toxicity endpoint in the literature applicable to aquatic life in Brucejack Creek; therefore no significant effects to aquatic life are expected, and residual effects were assessed to be not significant.

- The maximum Base Case prediction for antimony (14 µg/L) occurs during the Closure phase at BJ 2.62. This value is slightly higher than the maximum prediction in the 2015 MA-EMA Permits Application (10 µg/L) and higher than the BC FWAL working guideline (9 µg/L). Base Case Sb concentrations at both BJ 3.10 and BJ 2.62 are predicted to decrease to background levels by the end of the Closure phase. The predicted concentrations are well below the lowest toxicity endpoint applicable to aquatic biota in Brucejack Creek, therefore no toxicity to aquatic life in the receiving environment from Sb is expected, and residual effects were assessed as not significant.
- Base Case arsenic predictions at BJ 3.10 during Operations are approximately the same as the predictions in the 2015 MA-EMA Permits Application, with a maximum concentration of 6.5 µg/L, which is greater than the PE-107835 discharge limit of 5 µg/L. The updated predictions are that T-As will exceed the discharge limit earlier during Operations than was predicted for the 2015 MA-EMA Permits Application. Closure and Post-Closure predictions at BJ 2.62 are lower than in the MA-EMA application, with a maximum of 13 µg/L. The 2015 MA-EMA Permits Application concluded that T-As predictions would not have significan adverse effects to aquatic life. This conclusion is supported by a recent site specific toxicity test on species known to be sensitive to arsenic toxicity, since the maximum predicted concentration is lower than the No Observable Effect Concentration from the toxicity test.
- Fe concentrations are only predicted to exceed BC FWAL guidelines at BJ 2.62 during the Closure and Post-Closure phases when the underground mine is flooded and groundwater flows to Brucejack Creek. Post-closure iron in groundwater from the underground mine is expected to have solubility constraints when it enters Brucejack Creek. Redox-controlled reactions in Brucejack Creek will cause Fe to come out of solution and lower the dissolved concentrations to less than the BC water quality guidelines. Potential effects from precipitation of iron in Brucejack Creek were assessed as having low significance.

- The maximum Base Case Zn prediction (8.6 µg/L) is almost the same as the maximum prediction in the 2015 MA-EMA Permits Application (8.5 µg/L). These predictions are slightly above the BC FWAL guideline of 7.5 µg/L. The residual effects assessment in the 2015 MA-EMA Permits Application that concluded potential effects to aquatic life from predicted Zn concentrations are not significant is also valid for the updated Zn predictions.
- Discharge limits based on Operations phase Upper Case BJ 3.10 predictions are proposed for ammonia (4 mg-N/L), T-Sb (28 µg/L) and T-As (10 µg/L). The Base Case model results represent monthly average concentrations, whereas the Upper Case predictions are expected to capture the variability of BJ 3.10 sample measurements, which will be greater than the monthly average.
- The proposed effluent discharge limits for ammonia, T-Sb and T-As are below the most sensitive applicable toxicity endpoints for these parameters. As well, T-As predictions are below the No Observable Effects Concentration from a site-specific toxicity test. Based on these toxicity data, the proposed discharge limits are expected to be protective of aquatic life in the receiving environment.
- Cumulative effects of the proposed ammonia, Sb and As discharge limits and water quality predictions for the KSM mine in lower Sulphurets Creek were considererd not significant. The maximum loadings of ammonia, T-Sb or T-As from Brucejack Mine effluent would not cause the cumulative concentration to go above the BC FWAL guideline. Maximum KSM arsenic predictions of 10.9 µg/L would be negligibly changed by Brucejack Mine effluent with 10 µg/L As or Post-closure Brucejack Creek water with 13 µg/L T-As.

EXECUTIVE SUMMARY

Based on predicted influent water quality and flow, Veolia has proposed a process design for the Operations Water Treatment Plant (WTP). The Operations WTP design consists of:

- Primary metals removal using the Actiflo® process;
- Polishing metals removal using the Actiflo process; and
- Filtration of final effluent using Hydrotech Discfilter filtration process.

The treatment chain, which includes metals precipitation reactors, two Actiflo® process units and a Hydrotech Discfilter unit, was validated using bench-scale testing for the predicted influent upper-case maximum values (without Hydrotech filtration). Additional tests were needed to validate that higher As, Cd and Zn concentrations can be treated by the proposed design. These tests demonstrate that the treatment process as designed can meet the criteria for these metals. Specifically, the tests found that:

- Using the Actiflo® process bench-scale test for the primary metals removal step, the following combination of reagents and conditions was shown to work well: pH increase to 10.00 using a lime dosage of 340 mg/L, then addition of 35.0 mg S/L of sulfide (Na_2S), 27.5 mg Fe/L of Hydrex™ 6253 coagulant for metals removal, and 2.0 mg/L of Hydrex™ 6183 polymer to improve turbidity and metals removal with the Actiflo® process; and
- Using the Actiflo® process bench-scale test for the polishing metals removal step, the following combination of reagents and conditions was shown to provide water that met the criteria after polishing: pH decrease to 7.25, addition of 22.0 mg Fe/L of Hydrex™ 6253 coagulant for metals removal, and 1.5 mg/L of Hydrex™ 6183 polymer to improve metals removal.

A test with higher dissolved Arsenic concentration in the influent was also completed on a modified synthetic water to prove the efficiency of the arsenic removal of the process design proposed.

The details relating to the full-scale implementation, including the process flow diagrams, the design data and the annual chemicals consumption, are included in the "Brucejack Gold Mine Project Application for Mines Act and Environmental Management Act Permits" document.

SECTION 1. INTRODUCTION

Pretium Resources Inc. (Pretivm) is developing the Brucejack Mine Project (Brucejack Project), a high grade, large-scale gold project located in Northern British Columbia (BC).

On-site mine water treatment at the Brucejack Project will be managed in three phases:

- Exploration Phase;
- Construction Phase; and
- Operations Phase.

This report concerns the Operations Phase.

Pretivm has retained the services of Veolia Water Technologies Canada Inc. (Veolia) to design the Operations Water Treatment Plant (WTP). Bench testing was already done in February to April 2015 to demonstrate the efficiency of Actiflo® process for metals and total suspended solids (TSS) removal, in accordance to the raw water quality issued at this time. Two reports have been issued to present the obtained results of these tests (primary metals removal only and primary metals removal followed by polishing step) and the design of the Operations WTP has been completed accordingly. These reports, issued on April 24th and May 4th 2015, are presented in Appendix A ("5000196003_Brucejack_ Bench_test_Rev6_20150424" and "5000196003_Brucejack_Polishing_Rev3_20150504"). The process selected for the Operations WTP is described as follow:

- Primary metals removal using metal precipitation, ballasted flocculation and clarification (Actiflo®);
- Polishing metals removal using metal precipitation, ballasted flocculation and clarification (Actiflo®).

Results obtained during the Operations bench testing were meeting expectations, but the raw water quality used from both bench testing of the Operations WTP had lower than expected dissolved Arsenic (As), Cadmium (Cd) and Zinc (Zn) concentrations. Nonetheless,

these higher concentrations for As, Cd and Zn in the influent water are expected to be removed just as well with the proposed treatment processes, by adjusting the chemical dosage, coagulant and sulfide dosages mostly.

In order to validate the metals removal of the final expected upper-case raw water quality during Operations WTP exploitation, a new bench test program was therefore developed using the same technologies (modification of the chemical dosages only).

For this validation testing program, the following information has been considered:

- Predicted influent water quality as per Lorax Environmental (Lorax) simulations, issued on May 19th 2015 in a technical memo titled "Next round of bench-scale testing for the Brucejack Project", presented in Appendix B, adjusted with OLI simulation influent water (balancing of the influent water anions and cations concentrations) which Reconciliation Report is presented in Appendix C;
- Treated water quality targets to respect discharge criteria, as per Process Performance Guarantee, issued by Veolia according to previous bench testing conducted in February to May 2015 (Process Performance Guarantee is presented in Appendix D);
- Operations bench-scale laboratory testing results from previous testing (for TSS and metals removal in primary metals removal (bench test #1) and for metals removal in primary metals removal completed by polishing step (bench test #2)) for process validation and chemical dosage optimisation.

This report presents the materials and methods used to simulate the metals removal process at bench scale laboratory. Furthermore, this report provides the predicted treated water quality obtained according to this third bench-scale laboratory testing, and the metals removal process operating parameters which should be expected in the full-scale implementation (in worst-case influent composition) of the Operations WTP.

SECTION 2. OBJECTIVES

The main objectives of the bench-scale laboratory testing are to validate that the achievable treated water quality is in line with the Operations Phase water quality targets for metals removal with higher influent As, Cd and Zn concentrations and to validate the maximum chemical dosages required to meet total suspended solids (TSS), sulfate, sulfide and metal concentrations defined in the Performance Guarantee for Operations WTP.

Specifically, the following steps were taken to optimize treatment parameters during the bench scale tests:

- Preparation of a synthetic raw water to match the predicted influent water quality as closely as possible, with a particular attention to As, Cd and Zn dissolved concentrations; and,
- Simulation of the metals removal process in bench-scale laboratory (jar tests), i.e. using precipitation, coagulation-flocculation, settling and filtration for both the primary metals removal step and the polishing metals removal step.

The parameters to be optimised were the coagulant dosages (in primary metals removal and polishing metals removal steps) and sulfide dosage (in primary metals removal step only), as contact times, dosage sequencing and pH for metals precipitation were already optimised on the previous Operations bench testing program. Table 1 presents Veolia Performance guarantee for Operations WTP.

Table 1 Operations WTP Process Performance Guarantee (Monthly Average except where stated otherwise)

Parameters	Units	Final Effluent water quality (Veolia Process Guarantee for Operations Phase)
Total Suspended Solids (TSS)	**mg/L**	15
Sulfate	**mg/L**	Increase <200 through facility
Sulfide	**mg/L**	Increase <0.25 through facility
Phosphorus	**mg P/L**	0.1
Aluminium	**mg/L**	0.15
Arsenic	**mg/L**	0.005

Parameters	Units	Final Effluent water quality (Veolia Process Guarantee for Operations Phase)
Cadmium	**mg/L**	0.00012
Cobalt	**mg/L**	0.005
Copper	**mg/L**	0.005
Iron	**mg/L**	0.25
Lead	**mg/L**	0.0025
Manganese	**mg/L**	10
Silver	**mg/L**	0.0001 (Grab sample)
Zinc	**mg/L**	0.01

SECTION 3. SYNTHETIC RAW WATER

The Brucejack mine as not yet advanced to the Operations Phase and therefore does not produce influent water to be treated by the Operations WTP. The information regarding the influent water quality was obtained in Lorax technical memo, issued on May 19th 2015 and presented in Appendix C, and modified according to a simulation software (OLI) to ensure ionic balance. The OLI Reconciliation report is presented in Appendix C.

In order to simulate the metals removal process in jar tests, synthetic raw water was produced for the tests carried out in Veolia's laboratory using city water and commercially-available chemicals.

Veolia prepared synthetic raw water based on influent water quality predicted by Lorax, with adjustments to create a realistic composition based on OLI simulation software.

The influent water quality estimate does not represent a point in time, but includes the maximum concentration values for each parameter expected throughout the mine life, and is neither chemically nor electrically balanced. OLI simulation software was used to calculate the amount of sulfates ion (SO_4^{2-}) or salinity required to electrically balance the solution. No TSS was added to the synthetic water as Bench Test #1 (primary metals removal only, presented in Appendix A) validates the efficiency of the Actiflo process for TSS removal.

The synthetic raw water was prepared as follows:

1. City water was used to fill a 208-L plastic calibrated drum. Refer to Table 2 for the city water composition;
2. The City water was conditioned by letting it off-gas over a 24-hour period to remove chlorine. Two 2-L beakers were set aside for dissolution of monovalent and divalent salts prior to the addition in the drum.
3. Calcium sulfate was added to the city water and mixed for 24 hours to allow its complete dissolution. Refer to Table 3 for the quantity of calcium sulfate used;

4. During dissolution of calcium sulfate, in a separate 100 mL beaker, low mass salts were completely dissolved by adding 100X the concentration actually needed (sodium hexametaphosphate, lead chloride, nickel sulfate, sodium arsenate, sodium selenite and antimony sulfate);
5. 1 mL of the 100 mL beaker content, once dissolved, was added to the monovalent and divalent salts solution (corresponding to the salts addition required in low masses);
6. The metals solutions were added to the city water drum. Refer to Table 3 for the masses of chemicals added to the city water;
7. The synthetic raw water was mixed during a minimum of 2 days; and
8. After the mixing period, sufficient synthetic raw water was sampled from the drum without stopping the mixing and sent to ALS for completing the synthetic water characterization. Refer to Section **Erreur ! Source du renvoi introuvable.** for the compiled results of the ALS analysis and refer to Appendix E for the complete analysis and method used for the analyses (ALS certificates).

Table 2 shows the composition of the city water used to produce the synthetic raw water. Also, the target synthetic raw water composition is presented, as predicted by Lorax, once balanced with an OLI simulation conducted by Veolia in May 2015 (Appendix C).

Table 3 presents the chemicals and dosages used to produce the synthetic raw water.

Section 5.1 presents the resulting synthetic raw water quality used for the Operations WTP bench-testing program and Section 6.2 provides comments on the synthetic water composition (based on the raw water composition received from Lorax on May 19th 2015, once equilibrated with OLI simulation software by Veolia).

Since the dissolved arsenic concentration was lower than expected for the synthetic water constructed in Veolia's laboratory, it was modified by decreasing the pH and adding arsenic salt in order to achieve a higher dissolved As influent. This modified synthetic water is used to validate that arsenic can be removed at required Process Performance

Guarantee discharge criteria. The original synthetic water (before pH drop and excessive As dosage) is used to validate the removal efficiency of the process to achieve the Process Performance Guarantee for all metals concentration and is considered the real validation for this Operations WTP validation Bench test (the synthetic water is more representative to the expected Operations WTP influent in worst-case scenario). Validation of the arsenic removal is further tested with the modified synthetic water as higher dissolved arsenic concentration was achieved in the modified synthetic water.

Table 2: City Water Composition and Target Concentrations in Synthetic Raw Water from May 19th 2015 Influent Water Quality issued by Lorax, once balanced by OLI software

Parameters (Dissolved Metals, Anions, TSS)	Values

[3] Note that all Atomic Absorption Spectroscopy (AAS) standards are 1000 ppm and contain 1% nitric acid.

SECTION 4. MATERIALS AND METHODS

This section presents the materials and methods used to simulate the primary metals removal and the polishing metals removal processes in jar tests, using the synthetic raw waters (original for process validation and dosage determination, and modified at lower pH for validation of dissolved As removal) both produced in Veolia's laboratory.

4.1 Materials

The bench-scale testing was performed using a Phipps & Bird jar tester and 1-L cylindrical beakers, as shown in Figure 1.

Figure 1: Jar Test Set-Up

Table 4 summarizes the chemicals used during the jar tests program. The Material Safety Data Sheets (MSDS) of the chemicals used can be found in Appendix F.

Hydrated lime ($Ca(OH)_2$) is an inorganic compound use to raise the pH and to precipitate metals. The pH was raised to 10.0 for the primary metals removal and lowered to 7.25 for the polishing metals removal step. Lime was required to reach a pH of 7.25 during the polishing step even if the initial primary metals removal clarified water is at pH 10.0; the addition of coagulant in the polishing step, combined with the very low alkalinity of the water at this point in the process, cause a pH drop superior to what is needed to reach 7.25. Therefore, lime dosage might be needed in polishing step, as shown in the actual

Operations WTP Bench test. However, in full-scale implementation, sulfuric acid might be needed to lower the pH as the coagulant dosage will be inferior (the Operations WTP influent will not be as concentrate as the worst-case scenario synthetic water created in laboratory).

Sodium sulfide (Na_2S) was used to precipitate metals as sulfides in the primary metals removal process step. Many metal sulfides have much lower solubility than the corresponding metal hydroxide, thus allowing a lower residual metals concentration in the treated water. This is especially significant for cadmium and copper, as it would be difficult to reduce their concentration without sulfide. A high pH is required for the process to be efficient.

Metal hydroxides and sulfides form colloidal particles, whose removal requires the addition of a coagulant, in this case ferric sulfate (Hydrex™ 6253), to allow better solid-liquid separation downstream of the Actiflo®. Ferric sulfate forms a ferric hydroxide floc, which acts both as a bridge to bind colloidal particles together, and as an active surface which forms complexes with many metals, providing further metals removal in addition to the precipitation already achieved using hydroxides and sulfides.

The purpose of the polishing step is first to capture any solids remaining after the primary metals removal step and second, to trap anions such as arsenates, arsenites, antimonates, molybdates and chromates on the freshly-formed ferric hydroxide floc. In general, the capture of anions on the ferric hydroxide floc is more efficient at a lower pH.

An anionic polymer (Hydrex™ 6183) is used for flocculation.

The chemicals used were selected based on Veolia's experience and previous experimental and full-scale results. These were also the chemicals used in the two previous bench testing completed for the Operations WTP, which mean to be validated in the present bench testing.

Table 4: Chemicals Used During the Metals Removal Jar Testing

Chemicals	Formula	Purpose
Hydrated lime (15 g/L)	$Ca(OH)_2$	pH adjustment and metals precipitation
Sodium sulfide (14 g/L[4])	Na_2S	Metals precipitation in primary metals removal
Anionic polymer	Hydrex™ 6183	Flocculation
Ferric sulfate	Hydrex™ 6253	Coagulation
Actisand	Hydrex™	Ballasted decantation
Sulfuric Acid	H_2SO_4 98%	pH adjustment in polishing metals removal (if needed)

Each chemical's MSDS can be found in Appendix F.

All glassware and laboratory equipment that came into contact with the clarified primary metals removal effluent and with the final effluent was washed, rinsed with distilled water, rinsed with a 5% nitric acid solution and finally rinsed with distilled water. This procedure was applied to prevent and limit contamination since it has been a problem issue in previous bench tests, especially for the Operations WTP.

4.2 Methodology

Tests were performed in Veolia's laboratory, in Montreal, Quebec. Metal, anions and nutrients analyses were performed by the ALS Environmental (ALS) certified laboratory in Vancouver, BC (ISO 17025:2005 Accredited Laboratory). All samples were sent in duplicate for results validation purpose.

[4] The concentration of the sodium sulfide solution was measured using the Iodometric Method (4500-S2- F) of Standard Methods (2005).

4.2.1 Jar Tests Procedure

The synthetic raw water prepared as described in SECTION 3 was treated using jar tests to simulate the primary metals removal process, i.e. TSS and metals removal. Treated water resulting from the optimized primary metals removal process was replicated and treated using jar tests to simulate the polishing metals removal process, i.e. metals removal.

At full scale operation, the primary metals removal and the polishing metals removal processes are each achieved by Metals Removal Reactors and an Actiflo® unit.

Metals Removal Reactors are tanks to which chemicals are added, and which provide a reaction time as a function of their volume.

An Actiflo® unit is a sand-ballasted settling system designed to remove suspended solids present in the water. The Actiflo® is a high-rate coagulation/flocculation/sedimentation process that utilizes microsand as a seed for floc formation. The microsand provides a surface area that enhances flocculation and acts as a ballast or weight. The resulting floc settles very quickly, allowing for compact clarifier designs compared to conventional clarifiers, with high overflow rates and short retention times. The use of microsand also permits the unit to perform well under dramatically changing flow rates without affecting effluent quality.

The primary metals removal and the polishing metals removal processes are summarized respectively in Table 5 and in Table 6, where the chemicals used for each are summarized.

Table 5: Process Treatment Chain for Primary Metals Removal

Process Step	Process Name	Chemicals Added	Objectives
1	Primary Metals Reactors	hydrated lime sodium sulfide coagulant	pH adjustment and metals precipitation
2	ACTIFLO® (clarification using ballasted flocculation, currently used on-site)	anionic polymer actisand	decantation

Table 6: Process Treatment Chain for Polishing Metals Removal;

Process Step	Process Name	Chemicals Added	Objectives
1	Polishing Reactors	hydrated lime coagulant	pH adjustment and metals precipitation
2	ACTIFLO® (clarification using ballasted flocculation, currently used on-site)	anionic polymer actisand	decantation
3	Hydrotech Discfilter filtration[5]	None	Clarified water polishing

The jar test program is designed to reproduce the retention time in the Metals Removal Reactors and to simulate Veolia's Actiflo® ballasted flocculation technology. The test procedure to simulate the Actiflo® process is as per the paper included in Appendix G and published in Water Research (2002)[6]. The total retention time in the reactors is 20 minutes, divided into three equal compartments, and the time between chemical additions is calculated to match the expected addition sequence in the full scale plant. The test procedure used to simulate the primary metals removal process was the following:

1. Adjustment of pH using lime to bring the synthetic raw water to optimum metals removal conditions found in the previous bench tests, i.e. between pH 9.5 and 10.5;
2. Addition of sodium sulfide to the synthetic raw water after a defined contact time of 6.6 minutes (a retention time equivalent to one metal removal tank);
3. Addition of the ferric sulfate (coagulant-Hydrex™ 6253) a few seconds later to complete the metals removal reaction;
4. Addition of the anionic polymer (Hydrex™ 6183) and sand after 13.3 minutes (a retention time equivalent to two metal removal tank) to start the ballasted

[5] The full scale Operations plant is designed to allow for intercoagulation before the final filtration step. This intercoagulation, as well as the discfilter filtration, are difficult to reproduce on a lab scale, and are therefore not included in this test.

[6] Desjardins, C., Koudjonou, B., & Desjardins, R. (2002). 'Laboratory study of ballasted flocculation'. *Water Research*, 36, 744-754

flocculation process on the synthetic raw water and to complete the metals removal reaction;

5. Sampling of the clarified water produced after flocculation and settling and measurement of the TSS and metals concentrations. The tests were held at room temperature.

This test procedure was repeated with different coagulant and sulfide dosages. Sequence of dosage and optimal pH were taken from the two previous Operations WTP bench testing. The hydrated lime, sodium sulfide and coagulant dosages were optimised given the difference in water quality between the actual synthetic water and the second synthetic water produced for Operations WTP bench testing (higher As, Cd and Zn concentrations). Section 5.2 describes the different optimization tests made on this validation bench testing. The complete jar test results sheet can be found in Appendix H.

For the simulation of the polishing metals removal process, the test procedure is as follows:

1. Addition of the ferric sulfate (coagulant-Hydrex™ 6253);
2. Immediately after coagulant dosage, adjustment of pH using lime or sulfuric acid[7] to bring the synthetic raw water to optimum metals removal conditions, i.e. between pH 7.0 and 7.5;
3. After 20 minutes of retention time, the anionic polymer (Hydrex™ 6183) and sand were added to start the ballasted flocculation process on the synthetic primary-treated water and to complete the metals removal reaction;

[7] In the full scale plant sulfuric acid will be added; the coagulant dosage will be lower from the dosages currently tested and acidification of the water will then be needed. Because the water used in the tests has very little buffering capacity, it was extremely difficult to adjust the pH for polishing in at laboratory scale (in the 1 L samples).

4. The clarified water produced after flocculation and settling was sampled and the TSS and metals concentrations in it were measured. The tests were held at room temperature.

This test procedure was repeated with different coagulant concentrations. Section 5.3 describes the optimization made on the polishing step for this performance validation bench testing. The complete jar test results sheet can be found in Appendix H.

The effect of using a Discfilter was not evaluated as part of this test. The Discfilter is not especially beneficial at the lab scale where TSS concentrations of less than 3 mg/L are routinely achieved. In the full-scale plant, where TSS removal is often not as efficient, the Discfilter provides a reliable last line of defense, especially when combined with an intercoagulation step.

4.2.2 Monitoring

Monitoring during the two steps of the bench-scale test program (primary metals removal and polishing metals removal) was performed in two steps:

- The clarified water samples were first analysed in Veolia's laboratory to have an initial idea of the performance of the primary metals removal process jar tests. Refer to Table 7 for the parameters monitored during Primary Metals Removal Jar Tests and Polishing Metals Removal Jar Tests and their expected ranges; and,
- Samples with parameter values within the expected range and that were visually acceptable, i.e. with low turbidity, were then sent for analysis to ALS for chemical testing. The methods used for measuring the clarified water parameters are described in Table 8. All laboratory equipment was calibrated according to the supplier's operation manual prior to starting the jar testing program.

Table 7: Parameters Monitored during Primary Metals Removal and Polishing Metals Removal Jar Tests

Parameter	Unit	Clarified Water Samples	Expected Range
Turbidity	NTU	X	<5
pH	--	X	9.5 to 10.3
Copper	mg/L	X	Refer to method indicated in Table 8

[8] The acronyms and methods mentioned here are described in Standard Methods Manual

SECTION 5. RESULTS

5.1 Synthetic Raw Water Quality Results

5.1.1 Original Synthetic Raw Water Quality

The synthetic raw water quality used for the validation Operations bench testing is presented in Table 9. An adjustment on the As, Fe and Zn concentrations was made accordingly to the difference between the targeted synthetic water concentrations and the initial synthetic water composition obtained for Operations WTP validation bench test. Table 10 presents the quality of the adjusted synthetic water; Influent 3 presents the validation of the composition of the synthetic water prior to carry on with the bench testing and Influent 4 and 5 are samples representing the influent quality the day the bench testing was performed.

5.1.2 Modified Synthetic Raw Water Quality (for additional testing)

No matter the quantity of arsenic salt added to the synthetic water, the targeted dissolved As concentration could not be reached with the expected pH for the Operations WTP's influent. In order to prove the efficiency of dissolved arsenic removal in Actiflo process, additional tests were asked to Veolia on June 22nd via an email sent by Robert Goldblatt. It consists on lowering the pH of the dissolved fraction of the synthetic water, followed by the addition of arsenic salt.

Due to complication awaited by having only the dissolved fraction of the synthetic water for a large volume to prepare a new synthetic water and the delay it would have caused, settled water from the original synthetic water was taken instead.

pH adjustment was made using sulfuric acid and addition of arsenic was overdosed to make sure there was enough dissolved arsenic in the modified synthetic water. Water quality of the modified synthetic water is presented in Table 11.

Table 11: Modified Synthetic Raw Water Composition before Chemical Adjustment

The modified synthetic water was still not in compliance with the targeted dissolved arsenic concentration, but was increased compared to the original synthetic water for Operations validation bench tests. Arsenic (As) concentration was therefore adjusted prior to the launch of the additional bench test program. The chemically adjusted modified synthetic water for the additional arsenic removal bench testing is presented in Table 12.

5.2 Primary Metals and TSS Removal Jar Test Results- Original synthetic water

In order to simplify the reading of this section, Table 13 presents a resume of all the testing done for primary metals removal step. The pH target for all the presented tests was 10.0, as previously found in last Operations WTP bench testing programs.

Table 13: Overview of the tests done for primary metals removal step in Operations WTP validation bench testing program

Test ID	Sulfide dosage (mg S/L)	Coagulant dosage (mg Fe/L)	Purpose	Observations
o-1	42.0	18.3	Coagulant dosage selection	Green supernatant
o-2	42.0	22.9	Coagulant dosage selection	Clear supernatant

o-3	42.0	27.5	Coagulant dosage selection	Clear supernatant; dosage selected
o-4	42.0	32.0	Coagulant dosage selection	Clear supernatant
o-5	28.0	27.5	Sulfide dosage selection	Clear supernatant
o-6	35.0	27.5	Sulfide dosage selection	Clear supernatant; sent to ALS
o-7	42.0	27.5	Sulfide dosage selection	Clear supernatant
o-8	56.0	27.5	Sulfide dosage selection	Clear supernatant
o-Blank1er	35.0	27.5	Validation of contamination through chemical dosage on distilled water Discussed in Section 6.3	Pitch black and opaque supernatant; formation of big fluffy flocs after several hours- not considered
o-6A	35.0	27.5	Water production for polishing	Clear supernatant; sent to ALS
o-6B	35.0	27.5	Water production for polishing	Clear supernatant; sent to ALS
o-6P1	35.0	27.5	Water production for polishing	Clear supernatant; used for polishing

5.2.1 Coagulant Dosage Optimization

Optimization of the dosage sequence and the pH level, completed in the two previous Operations bench testing, showed that the best sequence of dosage is Lime addition, Sulfide/Coagulant addition, followed by the Actiflo ballasted flocculation process. The target pH level during the jar testing for primary metals removal was fixed at 10.0.

Four different coagulant dosages were tested to determine the best conditions for metals and TSS removal.

Table 14 presents a summary of the tests performed for the coagulant dosage optimization tests. Detailed results can be found in Appendix H.

Table 14: Coagulant Optimization Test for primary metals removal

Chemical dosages	Sulfide dosage: 42.0 mg S/L Polymer dosage (Hydrex™ 6183): 1.5 mg/L Target pH : 10.0 Lime addition, Sulfide/Coagulant addition, Actiflo©				
Sample ID	Coagulant dosage (Hydrex™ 6253)	Lime Dose	pH	Turbidity	Copper
	mg Fe/L	mg/L	-	NTU	mg/L
Influent	-	-	4.26	-	-
o-1	18.3	345	10.27	6.76	0.001
o-2	22.9	337.5	10.24	5.23	<0.001
o-3	***27.5***	***307.5***	***9.92***	***2.38***	***<0.001***
o-4	32.0	345	10.00	2.37	0

Sample o-1 presents a green coloration in the dissolved fraction of its supernatant, showing a lack of coagulant dosage. For all the tested coagulant dosages, the copper concentration measured was similar and low (below detection limit of the HACH method except for sample o-1). Turbidity of the clarified water was measured to be lower at higher coagulant dosage, with stagnation at a dosage of 27.5 mg Fe/L. For these reasons, and since the objective of the current bench testing is validation of the proposed Operations WTP process efficiency to treat influent higher As, Cd and Zn concentrations, a coagulant dosage of 27.5 mg Fe/L is selected as optimal for primary metals removal. Further optimisation will be possible later if requested or on the full-scale process itself. In the previous bench testing done for Operations WTP, with low TSS concentration (Bench Test #2; primary metals removal and polishing), the required coagulant dosage for the primary metals removal step was identified at 27.5 mg Fe/L. Even with higher As, Cd and Zn concentration in the influent, the coagulant dosage remains sufficient in the primary metals removal step of this validation Operations WTP bench testing.

5.2.2 Sulfide dosage Optimization

Four different sulfide dosages were tested to optimise its concentration in the metals and TSS removal tests. Note that maintaining the pH at a constant value is a challenge while varying sulfide concentration, as sodium sulfide increases the pH after lime addition. For this reason, pH was adjusted during the whole contact time, as it will be in the full-scale process.

Table 15 presents a summary of the tests performed for the adjustment of sulfide dosage. Detailed results can be found in Appendix H.

Table 15: Sulfide Optimization Test for primary metals removal

Chemical dosages	Coagulant dosage: 27.5 mg Fe/L				
	Polymer dosage (Hydrex™ 6183): 2.0 mg/L				
	Target pH : 10.0				
	Lime addition, Sulfide/Coagulant addition, Actiflo©				
Sample	Sulfide dosage	Lime	pH	Turbidity	Copper

ID	Na_2S	Dose			
	mg S/L	mg/L	-	NTU	mg/L
Influent	-	-	4.26	-	-
o-5	28.0	345	9.84	1.16	0.002
o-6	***35.0***	***360***	***9.99***	***1.72***	***0***
o-7	42.0	292.5	9.81	2.67	0
o-8	56.0	285	9.98	4.86	0

Little difference was seen between the water qualities for the primary metals removal with sulfide optimisation. Since sample o-5 presents higher copper concentration (removed mainly by sulfide precipitation) and that higher sulfide dosage causes higher turbidity at the clarified water, a sulfide dosage of 35.0 mg S/L was selected as the optimal one for this validation bench testing. At the previous tests done on Operations WTP projected influent, a sulfide dosage of 19.2 mg S/L was selected with lower As, Cd and Zn concentrations in the synthetic water.

This dosage was therefore selected to produce water in order to complete the polishing step of the Operations WTP. Table 16 presents the jar-test done to produce enough water to carry on the polishing tests and to analyse the water quality from the primary metals removal step. Table 17 presents the clarified water quality obtained from the primary metals removal step. Both o-6P samples were done applying the same jar-testing procedure, but using a 20-L pail and a mixer to produce a greater volume of primary metals removal clarified water.

5.3 Effluent Polishing- Original synthetic water

In order to simplify the reading of this section, Table 18 presents a resume of all the testing done for polishing metals removal step. The pH target for all the presented tests was 7.25.

Table 18: Overview of the tests done for polishing metals removal step in Operations WTP validation bench testing program

Test ID	Coagulant dosage (mg Fe/L)	Clarified water source	Purpose	Observations
o-11	18.3	o-6P	Coagulant dosage selection	Clear supernatant
o-12	22.0	o-6P	Coagulant dosage selection	Clear supernatant; dosage selected
o-13	25.6	o-6P	Coagulant dosage selection	Clear supernatant
o-14	29.3	o-6P	Coagulant dosage selection	Clear supernatant; dosage selected
o-12A	22.0	o-6P	Water production for ALS sampling	Clear supernatant; sent to ALS
o-12B	22.0	o-6P	Water production for ALS sampling (duplicate)	Clear supernatant; sent to ALS
o-14A	29.3	o-6P	Water production for ALS sampling	Clear supernatant; sent to ALS
o-14B	29.3	o-6P	Water production for ALS sampling (duplicate)	Clear supernatant; sent to ALS
o-Blank2e	29.3	Distilled water	Validation of contamination through chemical dosage on distilled water Discussed in Section 6.3	Clear supernatant; sent to ALS

5.3.1 Coagulant Dosage Optimization

Four coagulant dosages were tested to determine the best conditions for polishing metals removal. Table 19 presents a summary of the tests performed for the coagulant dosage optimization tests. Table 20 presents a summary of the tests for water production, once the coagulant dosages selected, in order to produce enough water for external laboratory analyses. Detailed results can be found in Appendix H. Table 21 and Table 22 present the certified external laboratory results from ALS for the polishing metals removal clarified water, issued from the polishing metals removal water production (for low coagulant dosage and for high coagulant dosage).

Table 19: Coagulant Optimization Test for polishing metals removal step

Chemical dosages	Polymer dosage (Hydrex™ 6183): 1.0 mg/L Target pH : 7.25 Coagulant addition, Lime addition, Actiflo©				
Sample ID	Coagulant dosage (Hydrex™ 6253)	Lime Dose	Sulfuric acid addition	pH	Turbidity
	mg Fe/L	mg/L	mg/L	-	NTU
o-6P (influent)	-	-	-	9.26	-
o-11	18.3	28.5	1.96	6.59	0.17
o-12	***22.0***	***33.0***	***-***	***6.70***	***0.168***
o-13	25.6	39.0	-	6.92	0.168
o-14	***29.3***	***51.0***	***-***	***6.98***	***0.188***

Visually, there is no difference between the quality of all the samples; all supernatant are clear and metals concentrations are below the detection limits of the internal laboratory analysis. Turbidity for the four samples is also similar. In order to validate the process, the higher dosage was therefore selected, as well as an intermediate one, to compare both removal performances. Therefore, samples o-12 and o-14 were selected, with coagulant dosage of respectively 22.0 mg Fe/L and 29.3 mg Fe/L.

These dosages were therefore selected to produce water in order to complete the polishing step of the Operations WTP. Table 20 presents the jar-test done to produce enough water to analyse the water quality from the polishing metals removal step. Table 21 and Table 22 present the clarified water quality obtained from the polishing metals

removal step. All o-12A samples, o-12B samples, o-14A samples and o-14B samples were done applying the regular jar-testing procedure (in 1L beakers), but the final samples o-12A, o-12B, o-14A and o-14B are a mix of 3 different jar-test (with the same dosages and sequencing) in order to accumulate enough water to carry on all the required analyses on the polishing metals removal clarified water.

Table 20: Water production for polishing metals removal (final effluent of Operations WTP bench testing)

Chemical Dosages	Polymer dosage (Hydrex™ 6183): 1.5 mg/L Target pH : 7.25 Lime addition, Sulfide/Coagulant addition, Actiflo©

Once all results were received, it was found that a 22.0 mg Fe/L coagulant dosage is sufficient to meet the Process Performance Guarantee of the Operations WTP. Should the concentration of cadmium increase, or should the criteria become stricter, the dosage of ferric iron could be increased as needed as the addition of ferric coagulant decreases the polished clarified water Cd concentration. No conclusion can be done for As and Zn, as both are below detection limits and no variation can be seen on the concentration of those metals with coagulation variation.

5.4 Additional testing for dissolved As removal- Modified synthetic water

The synthetic water quality was not exactly up to Lorax prediction, as the dissolved arsenic concentration was lower than expected even at high total concentration levels. In order to prove that the arsenic concentration at the synthetic water will not affect the performance of the Operations WTP, and it will still meet the Process Performance Guarantee, additional tests were asked. Those tests consist to lower the synthetic water pH and add arsenic. The preparation for this synthetic water was discussed in SECTION 3.

Since the validation of the process was already completed for Operations WTP at this point, the additional jar test was done on the higher polishing dosage sequence tested (same dosages and sequence were applied on the primary metals removal step than found for the validation bench tests described in Sections 5.2 and 5.3). The additional jar tests completed on June 29th, with higher arsenic concentration, are presented in Table 23 and Table 25 (for primary metals removal and for polishing metals removal). Table 24 and Table 26 present respectively the water quality obtained from the primary metal removal step and the polishing metal removal step of these additional tests, as measured by ALS.

SECTION 6. DISCUSSION

6.1 Review of Synthetic Raw Water Target concentrations selection

In order to produce a synthetic water representative of the Brucejack Mine Operations WTP, the water composition targeted (Target at Equilibrium) was the modelled influent water predicted by Lorax and presented in the technical memo "Next round of bench-scale testing for the Brucejack Project" issued on May 19th, once chemically balanced with OLI software. The comparison of the Target at Equilibrium and the final synthetic water composition is presented in Section 6.2. The Target at Equilibrium is based on total species, in order to achieve dissolved targeted concentrations in the synthetic water after chemical addition.

This Target at Equilibrium could differ on the modelled water composition as provided by Lorax, as it was considered impossible to have these concentrations while keeping the synthetic water chemically and electronically balanced. The differences between the model issued by Lorax on May 19th, and its balanced match, are presented in Table 27.

Table 27: Comparison of Synthetic Raw Water targeted Composition with Lorax's influent predictions

Parameters	Lorax Influent modeling (Dissolved) May 19th 2015	Target at Equilibrium[10] (Dissolved)
	mg/L	mg/L
Total suspended solids	n/a	n/a

Sodium (Na)	209	209
Zinc (Zn)	9.6	9.6

n/a: no target determined for these parameters (no addition in the synthetic water required)

The composition of the Operation WTP influent by Lorax, provided on May 19th, is at equilibrium; the target at equilibrium, obtained through OLI simulation, presents the same concentrations as expected from Lorax modeling. Therefore, the tested synthetic water should be as expected from the worst case scenario influent of the Operations WTP.

6.2 Review of Synthetic Raw Water Production

The city water was analyzed and found to have lower concentrations of all dissolved species than the predicted influent water quality provided by Lorax on May 19th 2015, and balanced by OLI software by Veolia. The concentrations of chemicals to be added to the synthetic raw water were calculated by taking into account the total target concentrations, and those of the dissolved species already present in the city water.

Three samples were sent for analysis of the final synthetic raw water used for the Operations metals removal validation Jar Test. An additional three samples were sent for

analysis for the additional high As concentration jar tests (modified synthetic water with lower pH and higher dissolved As concentration).

6.2.1 Original synthetic water composition

The analyses on the original synthetic water, used for the validation of the process with higher Cd and Zn concentration, were completed on June 15th, 2015 before chemical adjustment and after the chemical adjustment made on June 18th, 2015. These analyses show that the synthetic raw water quality is stable over the time it was completed and the moment the Operations bench tests were hold. The composition of the synthetic raw water used for the Operations bench tests was then compared with the target for its composition, as supplied by Lorax and modified for chemical balance by OLI software, by Veolia (see discussion in Section 6.1).

Table 28 compares the mean concentrations of the stabilized synthetic raw water in total and dissolved fractions, for both the synthetic water composition before and after chemical adjustment, with the target concentrations at equilibrium as predicted by Lorax on May 19th, 2015, modified according to OLI simulation on equilibrium proceed by Veolia.

n/a: not available

* Adjusted concentrations on June 18th, 2015.

The highlighting of values presented in the previous table is explained below.

Most of the metals concentrations in the synthetic raw water are close to the target values of Lorax. When comparing the synthetic raw water to predicted influent water concentration, after the chemical adjustment (final influent water quality), the following observations can be made:

- Cl, K, Na and nitrate concentrations are above the targeted value for the synthetic water. This can be explained as these elements were added by salts needed for other metal concentrations, which were considered more critical. Chloride concentration was also higher than targeted in the City water. These elements are presented in underlined green in Table 28;
- As and Zn, being considered critical elements of the validation bench test for Operations WTP testing, and Fe, being essential in determining the chemical dosage needed to obtain sufficient removal efficiencies, had lower dissolved concentration prior adjustment (but the total concentration was meeting the targeted concentration for the synthetic water). They are shown is blue in Table 28. Addition of As, Fe and Zn was made during adjustment of the synthetic water on June 18th, 2015. This addition was sufficient to meet the targeted dissolved concentration of Zn by increasing the total concentration over the targeted value, but target was not achieved for neither dissolved As and dissolved Fe. Dissolved Fe is however considered as sufficient after chemical adjustment, being nearer from its target. Further adjustment was also discourage in order to prevent any disequilibrium of the actual chemical equilibrium;
- Sb, Cr, Pb and Ag, presented in red in Table 28, show total concentrations according to the target concentrations for these metals. However, the dissolved concentrations in the synthetic water are below the target value. In order to prevent any disequilibrium of the synthetic water chemistry, and since none of these concentrations were critical to be removed during the bench testing, these metal concentrations were kept like this for the Operations bench testing; and

- Al and nitrite, presented in highlighted red in Table 28, have concentrations below the expected synthetic water composition. Since those two parameters are not critical to meet the Process Performance Guarantee requirements, Operations bench testing was made with those lower metal concentrations.

Overall, the final quality of the synthetic raw water, for total fraction and dissolved fraction, is representative of the Lorax model provided on May 19th 2015, and ionic balance by OLI software by Veolia. Target concentrations are modelled concentrations, and may be hard to reach in real influent water. Considering the complex chemistry of the synthetic raw water, the synthetic raw water blended for the metals removal demonstration is considered representative of the Lorax modeled influent water once chemically balanced, as provided on May 19th 2015. The validation bench testing was therefore made on this synthetic water quality.

6.2.2 Modified synthetic water composition

Arsenic dissolved concentration was below the expected concentration from Lorax's modelisation, no matter the quantity of salt added to the synthetic water. In order to prevent the modification of the chemical balance of the synthetic water, as all the other chemical elements were up to their targeted concentration, a modified synthetic water was created after the process validation to validate the As removal only. This modified synthetic water comes from the settled synthetic water (dissolved fraction mainly) of the original synthetic water, which was acidified before adding more As salt to it. Table 29 compares the mean concentrations of the modified synthetic raw water in total and dissolved fractions, for both the modified synthetic water composition before (with pH modification and As concentration modification, on June 25th 2015) and after chemical adjustment (June 29th 2015, with As concentration modification only), with the target concentrations at equilibrium as predicted by Lorax on May 19th, 2015, modified according to OLI simulation on equilibrium proceed by Veolia.

Table 29: Comparison of Modified Synthetic Raw Water Composition (Average on Stabilized Water Date) with Predicted Brucejack Influent Water Quality (Dissolved Fraction)

* Adjusted concentrations on June 29th, 2015.

The highlighting of values presented in the previous table is explained below.

Most of the metals concentrations in the synthetic raw water are close to the target values of Lorax, or at least close to the analysis made in Table 28. When comparing the modified synthetic raw water to predicted influent water concentration, after the chemical adjustment (final influent water quality for high As concentration testing), the following observations can be made:

- As, being considered a critical element of the validation bench test for Operations WTP additional testing, had lower dissolved concentration prior adjustment (but the total concentration was exceeding the targeted concentration for the synthetic water). It is shown is blue in Table 28. Addition of As was made during adjustment of the synthetic water on June 29th, 2015. This addition was still not sufficient to meet the targeted dissolved concentration of As, even at low pH conditions. Considering the total As concentration, and considering the predicted water is the worst-case scenario, it was state that it would be really hard to reach the proposed As dissolved concentration in real-life Operations water and additional testing was made with this As concentration.

6.3 Contamination of the clarified water

During previous bench test done for Construction and Operations WTP, questioning was made on the possible contamination of the samples due to the injection of coagulant, polymer and acid/base, especially between the primary metals removal step and the polishing step. In order to prevent any further interrogation on the subject, a blank test was done between those two critical steps. It consists of a regular Actiflo bench test procedure, but applied on distilled water instead of the raw synthetic water. The same dosage was applied on this blank sample than the water production for the polishing step (the most affected by the contamination). The higher chemical dosage tested was used for this verification (coagulant dosage of 27.5 mg Fe/L and sulfide dosage of 35.0 mg S/L for the primary metal removal step prior to this test, and coagulant dosage of 23.9 mg Fe/L for the polishing step now tested.

No contamination test was done for the primary metal removal, as sulfide and coagulant react together creating a black and opaque supernatant, which later flocculates with big fluffy brown flocs. For this reason, the blank contamination test was not further carried for the primary metals removal step and is only presented for the polishing metal removal step.

The same laboratory material (beaker, pipet, pH probes) were used for this blank test than for the regular Operations bench test. The results from this blank bench tests are presented in Table 30.

Table 30: ALS analysis results for blank bench tests (testing done on June 25th 2015)

Vanadium (V)	**mg/L**	<0.00050	<0.00050
Zinc (Zn)	**mg/L**	<0.0030	0.0015

No major contamination can be seen with the blank bench testing. All metals concentrations are low and far from the Process Performance Guarantee discharge criteria, which proves the chemicals injected in the process for metal removal do not interfere with the removal efficiency of the said process.

Moreover, no serious contamination, due to chemical dosage, was seen while executing the blank bench test on distilled water with the higher tested dosages of Operations WTP bench testing, which was executed in worst-case scenario dosages (higher contamination risks).

6.4 Clarified and filtered Water Quality with Respect to Process Performance Guarantee

Table 31 provides the Process Performance Guarantees as set by Veolia for Operations WTP, compared with the polished (clarified) Operations bench test water. The lower coagulant dosage is represented in the following comparison as it meets all performance guarantees for the Operations WTP.

Table 31: Validation of Operations WTP Bench Testing in accordance with Process Performance Guarantee

Parameters	Units	Performance guarantee (Monthly average except otherwise noted)	Primary Metals Removal Results, Mean Value of Duplicate Optimised Reagent Concentrations		Polishing Metals Removal Results, Mean Value of Duplicate Optimised Reagent Concentrations	
			Total	Dissolved	Total	Dissolved
Total suspended solids (TSS)	mg/L	15	10.1	-	<7.0	-
Phosphorus (P)	mg P/L	0.1	<0.0020	-	0.0255	-
Sulfate (SO_4)	mg S/L	907[11]	-	825	-	843
Sulfide	mg S/L	0.25[12]	-	0.0295	-	<0.020
Aluminum (Al)	mg/L	0.15	0.578	0.531	<0.015	0.00835
Arsenic (As)	mg/L	0.005	0.00663	0.004225	0.00216	<0.00050
Cadmium (Cd)	mg/L	0.00012	0.000238	0.000052	0.0000825	0.000077
Cobalt (Co)	mg/L	0.005	<0.00050	<0.00050	0.00144	0.00141
Copper (Cu)	mg/L	0.005	<0.0025	<0.0010	<0.0025	0.003
Iron (Fe)	mg/L	0.25	0.1005	<0.050	<0.050	<0.050
Lead (Pb)	mg/L	0.0025	<0.00025	<0.00025	<0.00025	<0.00025
Manganese (Mn)	mg/L	10	1.5	1.4	1.3	1.2
Silver (Ag)	mg/L	0.0001 (Grab sample)	<0.000050	<0.000050	0.0000915	0.0000755
Zinc (Zn)	mg/L	0.01	0.021	<0.0050	<0.015	<0.0075

There is to be noted that some contamination was seen during these jar test, even with all the precautions taken to prevent it. Higher Cobalt, Copper and Silver concentrations are

[11] Value depending on the influent concentration; the maximum concentration at the discharge is an addition of 200 mg/L of sulfate to the initial influent concentration (addition of 200 mg/L in the process)

[12] Value depending on the influent concentration; the maximum concentration at the discharge is an addition of 0.25 mg/L of sulfide to the initial influent concentration (addition of 0.25 mg/L in the process)

seen in the polishing effluent than in the primary metal removal step. These elements are shown in blue in Table 31.

Otherwise, all results presented in Table 31 show that all the metals were treated to below the required Process Performance Guarantee, even with higher As, Cd and Zn metals concentrations in the influent water than already tested with this process and at the lower coagulant dosage tested for polishing metals removal.

With all due considerations, validation of the chosen process design is therefore complete for the Operations WTP at the tested conditions (with slightly lower dissolved As concentration at the influent). Additional testing with higher As concentration at the influent is presented in the following section.

6.5 Clarified and filtered Water Quality with Respect to Process Performance Guarantee- Validation of As removal test on Modified Synthetic Water

Table 32 provides the Process Performance Guarantees as set by Veolia for Operations WTP, compared with the polished clarified Operations bench test water obtained during the validation of the process at higher As concentrations at the influent (Modified Synthetic Water bench testing).

Table 32: Validation of Operations WTP Bench Testing in accordance with Process Performance Guarantee- Validation for higher As concentrations with Modified Synthetic Water

Parameters	Units	Performance guarantee (Monthly average except otherwise noted)	Primary Metals Removal Results, Mean Value of Duplicate		Polishing Metals Removal Results, Mean Value of Duplicate	
			Total	Dissolved	Total	Dissolved
Total suspended solids (TSS)	mg/L	15	4.9	-	<3.8	-
Phosphorus (P)	mg P/L	0.1	-		-	<0.020
Sulfate (SO_4)	mg S/L	907[13]	-	847	-	860

[13] Value depending on the influent concentration; the maximum concentration at the discharge is an addition of 200 mg/L of sulfate to the initial influent concentration (addition of 200 mg/L in the process)

Parameters	Units	Performance guarantee (Monthly average except	Primary Metals Removal Results, Mean Value of Duplicate		Polishing Metals Removal Results, Mean Value of Duplicate	
Sulfide	**mg S/L**	<0.25[14]	n/a	-	0.026	-
Aluminum (Al)	**mg/L**	0.15	0.747	0.6905	<0.015	0.0051
Arsenic (As)	**mg/L**	0.005	0.002535	0.00189	<0.00071	<0.00050
Cadmium (Cd)	**mg/L**	0.00012	0.00017	<0.000025	0.00034	0.00062
Cobalt (Co)	**mg/L**	0.005	<0.00050	<0.00050	0.00236	0.002275
Copper (Cu)	**mg/L**	0.005	<0.0025	<0.0010	<0.0025	0.0035
Iron (Fe)	**mg/L**	0.25	0.1025	<0.050	0.069	<0.050
Lead (Pb)	**mg/L**	0.0025	<0.00025	<0.00025	<0.00025	<0.00025
Manganese (Mn)	**mg/L**	10	1.7	1.5	1.5	1.5
Silver (Ag)	**mg/L**	0.0001 (Grab sample)	<0.000050	<0.000050	0.000108	0.0000855
Zinc (Zn)	**mg/L**	0.01	0.016	<0.0050	<0.015	0.0059

All the metals were treated to below the required design criteria, with the exception of cadmium and silver, presented in red in Table 32.

- Silver was removed by the primary metals removal; however it was detected after the polishing step. It is shown in red in Table 32. Silver concentration must be due to contamination introduced between the primary metals removal step and the polishing metals removal step during the laboratory bench testing.
- One of the sample for the polishing step shows a higher cadmium concentration than after primary metals removal step, increasing the average. Contamination had therefore being introduced between the primary metals removal and polishing metals removal for only one of the samples, probably while sampling the polishing effluent.

Cobalt and Copper also show sign of contamination, the polishing step concentrations being higher than the primary metal removal step. These elements are presented in blue in Table 32.

[14] Value depending on the influent concentration; the maximum concentration at the discharge is an addition of 0.25 mg/L of sulfide to the initial influent concentration (addition of 0.25 mg/L in the process)

Controlled source of contamination, which would be the chemical injection during the bench testing (coagulant, lime and flocculent) were proven to be non-existent at the working dosage. Therefore, this contamination could only be explained by a manipulation in the laboratory, which would not be reproduced in the full-scale application. The efficiency of silver removal, rightfully removed during primary metal removal step, as well as the efficiency of cadmium removal, being proved on one of the sample (the other sample being over the primary metal removal step concentration) are therefore satisfactory, which leads to the conclusion that the polishing metals removal effluent is meeting all the Process Performance Guarantee.

The removal of the higher arsenic influent is therefore validates through this additional bench testing.

SECTION 7. CONCLUSION

Bench testing using synthetic raw water produced in Veolia's laboratory were performed to test TSS and metals removal using a process treatment chain composed of metal precipitation and Actiflo® ballasted flocculation primary metals removal, followed a second metal precipitation and Actiflo® ballasted flocculation system for polishing metals removal. The clarified water thus produced allowed treatment of all metals to below the Operations WTP Process Performance Guarantee. The main conclusions of the Operations WTP removal process bench scale tests are the following:

- The synthetic raw water can be treated to meet the Operations Process Performance Guarantee using two consecutive Actiflo® clarification processed for primary metals removal and for polishing metals removal;
- The reagent dosage sequence used during those tests was the following: pH adjustment, then sulfide and coagulant dosage (near simultaneous) for metal conditioning, followed by Actisand and polymer dosage for flocculation and precipitate removal using the Actiflo® process for the primary metals removal. The reagent dosage sequence used for the polishing metal removal was the following: pH adjustment, than coagulant dosage for metal conditioning, followed by Actisand and polymer dosage for flocculation and precipitation using the Actiflo® process;
- Using the Actiflo® process bench-scale test for the primary metals removal and for the polishing metals removal, the following combination and concentrations of reagents was shown to produce treated water with a quality exceeding the water quality target (Process Performance Guarantee for Operations WTP): 27.5 mg Fe/L of Hydrex™ 6253 coagulant for metals removal, 35.0 mg S/L of sulfide (Na_2S), Actisand dosage of 10 g/L and 2.0 mg/L of Hydrex™ 6183 polymer to improve turbidity and metals removal for primary metals removal. For polishing metal removal, the reagents used were: 22.0 mg Fe/L of Hydrex™ 6253 coagulant for metals removal, Actisand dosage of 10 g/L and 1.5 mg/L of Hydrex™ 6183 polymer to improve metals removal for polishing metals removal;
- The optimum pH for metals removal under test conditions is 10.0 for primary metals removal, with a hydrated lime dosage of 340 mg/L, and 7.25 for polishing metals removal, with a

hydrated lime dosage of 36 mg/L (the pH drops lower than 7.25 with the addition of coagulant, needing lime to stabilise the pH to 7.25; and

- Additional tests, with higher As concentrations at the influent, proved the achievement of the target concentrations for Process Performance Guarantees with a slightly higher dosage for the polishing metal removal (29.3 mg Fe/L instead of 22.0 mg Fe/L).

Additional improvement of most metals (As, Cd, Cu, Cr, Fe, Pb and Zn) removal could be accomplished if needed by simply increasing the coagulant dosage, as proved with this validation bench-testing with higher As, Cd and Zn concentration in the synthetic water than the previous bench-testing performed for the Operations WTP (presented in Appendix A).

APPENDIX A. OPERATIONS WTP BENCH TESTS REPORTS

-“5000196003_BRUCEJACK_ BENCH_TEST_REV6_20150424”

APPENDIX B. LORAX'S TECHNICAL MEMO FOR INFLUENT WATER QUALITY "NEXT ROUND OF BENCH-SCALE TESTING FOR THE BRUCEJACK PROJECT"

TECHNICAL MEMO

To:	Marc Laliberte (Veolia)
From:	Robert Goldblatt (Lorax)
cc:	Adam King (Pretivm), Patrick Mueller (Lorax)
Date:	19-March-2015 **Project #**: 384-2 (WTP)
Subject:	Next round of bench-scale testing for the Brucejack Project

1. Introduction

This memo is intended to provide Veolia Water Technologies Canada (Veolia) with details of the next round of bench scale testing of water treatment plants being designed for the Brucejack Mine Project (the Project). The primary objective of these tests is to provide solid evidence of the expected treated effluent concentrations that were used to model water quality during Construction and Operations phases of the Brucejack Gold Mine Project. A second objective is to provide data on sulphide concentration in treated effluent. A third objective is to repeat the Operations phase bench-scale test, which had a contamination issue for some metals, to provide results that are free of contamination.

Veolia will be constructing and operating two different mine water treatment plants (MWTP) for the Project, one for the Construction phase and another Operations phase. The two plants are designed with different treatment processes designed to treat the modeled influent quality for Construction and Operations phases of the mine. Bench-scale testing has been conducted by Veolia in order to optimize the treatment processes, including determining optimal pH and chemical dosing. The results of these bench-scale tests, as well as data from the existing Exploration phase MWTP, have been used by Lorax and Veolia to derive conservative estimates of expected effluent quality. MWTP effluent quality is an important component of the water quality estimates of water quality in Brucejack Creek, which were presented in Pretivm's application for *Mines Act/Environmental Management Act* permits.

Reviewers of the *MA/EMA* application may have questions about the MWTP effluent source terms used in the water quality model. In order to be able to quickly address possible questions from reviewers, Lorax has reviewed bench-scale results to date and identified strengths and potential questions that may arise. The tests to date have demonstrated the ability of the MWTPs to remove suspended solids and associated particulate metals. Dissolved metals are also removed from influent to the levels equal to or lower than the concentrations used in the water quality model. A potential comment from reviewers may be that some the influent concentrations tested are lower than the maximum upper case predictions, for certain parameters of interest. In particular, the water quality model assumptions regarding effluent

quality would be strengthened by bench-scale tests of higher influent concentrations of dissolved forms as As, Cd, and Zn for the Construction WTP and dissolved As for the Operations WTP.

As with previous bench-scale tests, Veolia will prepare a synthetic raw water which will be treated using the MWTPs processes, at a bench-scale in the Veolia laboratory. Details regarding these bench-scale tests are provided below.

2. Synthetic Raw Water

Lorax is requesting testing of influent that approximates the highest potential concentration of each parameter of interest during the Construction and Operations phases of the Project (Table 2-1). It is recognized that it is highly unlikely that the highest concentration of all parameters would occur together in influent to the MWTP. Nonetheless, it is desirable to test this mixture of parameters in order to prove to reviewers that the MWTPs can address the worst-case scenario for each parameter.

It is also recognized that the chemical mixture in Table 2-1 is not chemically stable, therefore Veolia is requested to modify the chemical balance of the synthetic raw water to produce a chemically stable synthetic raw water for testing. Seeing as the primary objective is to test upper case concentrations of As, Cd, and Zn, the balancing of other parameters should be done to ensure stable concentrations of As, Cd, Zn that are close to the concentrations in Table 2-1

Table 2-1
Target Concentrations of Parameters of Interest in Synthetic Raw Water

		Synthetic Raw Water Concentration	
Parameter	**Unit**	**Construction WTP**	**Operations WTP**
Ammonia	mg/L	3.1	6.6
Nitrate	mg/L	17.2	36.3
Nitrite	mg/L	0.89	1.9
Dissolved orthophosphate	mg/L	0.041	0.14
Chloride	mg/L	6.9	29.3
Fluoride	mg/L	0.90	3.8
Sulphate	mg/L	493	2091
Al-D	mg/L	0.23	28.6
Sb-D	mg/L	0.042	0.20
As-D[1]	mg/L	0.14	0.39
Cd-D[1]	mg/L	0.0078	0.068
Cr-D	mg/L	0.0028	0.49
Co-D	mg/L	0.014	0.061
Cu-D	mg/L	0.22	0.75
Fe-D	mg/L	0.030	64.7

		Synthetic Raw Water Concentration	
Parameter	**Unit**	**Construction WTP**	**Operations WTP**
Pb-D	mg/L	0.0063	0.013
Mn-D	mg/L	2.5	53
Ni-D	mg/L	0.041	0.14
Se-D	mg/L	0.004	0.019
Ag-D	mg/L	0.000050	0.00032
Zn-D[1]	mg/L	3.3	9.6
Ca-D	mg/L	167	650
Mg-D	mg/L	15	42
K-D	mg/L	17	219
Na-D	mg/L	44	209

1. When balancing the chemical stability of the influent solution, other parameter should be adjusted to derive concentrations of As, Cd, and Zn close to the values listed.

Since chemical speciation affects treatment of some metals, it is necessary to specify speciation of arsenic, chromium, iron, and selenium.

For Construction Phase tests, synthetic raw water will be created using As(V), Cr(III), and Se(VI). No iron will be added, since addition of Fe(III) to raw water may remove parameters of interest.

For Operations Phase, synthetic raw water will be created using As(III), Cr(III), Fe(II), and Se(IV). It should be noted that although Cr will leach as Cr(VI) from cemented paste backfill during Operations, the chromium management plan will be followed to reduce Cr(VI) to Cr(III) before it is treated in the MWTP.

Only the dissolved form of metals will be used when creating synthetic raw water. Removal of particulate metals has been demonstrated in previous bench-scale tests, therefore no suspended solids will be added for this round of testing.

3. Bench-scale Test Procedures

The following points should be incorporated into the upcoming bench-scale test procedures:

- Bench-scale tests will be run at the optimal pH and reagent doses determined in previous tests.
- Construction plant tests will collect & analyze samples of influent and treated water.
- Operations plant tests will collect & analyze samples of influent, after the primary metal removal step, and after the polishing step.
- Duplicates of each sample will be collected and analyzed.

- Operations plant test will add sulphide to the list of parameters analyzed.
- Samples will be analyzed at ALS Environmental in Burnaby, BC. Lorax will arrange for ALS to ship sample bottles and preservative to Veolia. Samples will be analysed for anions and metals.

4. Quality Control

ALS will ship deionized water for use as a blank. Deionized water is typically shipped in 4 L jugs.

A blank sample will be collected by transferring deionized water to sample bottles and preserving.

Prior to testing synthetic raw water, a procedure blank sample will be tested. The procedure blank will be deionized water that is subjected to the same bench-scale test as the synthetic raw water.

APPENDIX C. OLI OPERATIONS WTP RECONCILATION REPORT FOR TARGETED SYNTHETIC WATER COMPOSITION

Reconciliation Summary

APPENDIX D. VEOLIA OPERATIONS PROCESS PERFORMANCE GUARANTEE

PRETIUM RESOURCES INC.

BRUCEJACK MINE

Attention: Adam King

DRAFT PROCESS GUARANTEE

BRUCEJACK OPERATIONS WTP

2015-04-28, REVISION 2

PROPOSAL NUMBER TIH73855

PREPARED BY:
MARC LALIBERTÉ, SENIOR PROCESS ENGINEER, INDUSTRIAL

Veolia Water Technologies Canada
ISO 9001: 2008
4105 Sartelon, St-Laurent (QC) H4S 2B3
Tél: 514 334-7230 ● Fax: 514 334-5070
www.veoliawatertechnologies.ca

PROPRIETARY NOTICE
This proposal is confidential and contains proprietary information.
It is not to be disclosed to a third party without the written consent of Veolia Water Technologies Canada.

SECTION 1. DEFINITIONS

Supplier: Veolia Water Technologies Canada Inc. ("Veolia")

Owner: Pretium Resources Inc.

Facility: Operations Water Treatment Plant at Brucejack Mine, British Columbia, as defined in the Process Flow Diagram revision PP.

Guarantee Period: As long as conditions in section 2.1 are met

SECTION 2. PROCESS GUARANTEE

2.1 CONDITIONS OF APPLICATION

This Process Guarantee will only be applicable if all of the following conditions are met:

- The WTP Facility is operated and maintained by Veolia or under the direct supervision of Veolia; and
- The chemical products dosed are supplied or approved by Veolia; and
- The Microsand is supplied by Veolia; and
- The Facility Influent characteristics are generally similar to the predicted values for the case "Upper Case Adit Treatment v3 2015-03-19", an extract of which is presented in Table 1; and
- The Facility Influent flow rate and Total Suspended Solid content do not exceed the values in Table 1; and
- The Facility Influent does not contain any inhibitor or components that could affect or interfere with the normal performance of the Facility, including but not limited to, as a result of a chemical spill.

Table 1 Influent Characteristics

Parameter	Median Conditions	Worst Case Conditions
Flow rate	4 500 m^3/d	10 000 m^3/d
Total Suspended Solids	1 300 mg/L	2 000 mg/L
Total Silver	0.0089 mg/L	0.0097 mg/L
Total Aluminium	42 mg/L	47 mg/L
Total Arsenic	0.86 mg/L	1.1 mg/L
Total Cadmium	0.034 mg/L	0.072 mg/L
Total Cobalt	0.055 mg/L	0.090 mg/L
Total Copper	0.53 mg/L	0.90 mg/L
Total Iron	140 mg/L	150 mg/L

Parameter	Median Conditions	Worst Case Conditions
Total Manganese	50 mg/L	55 mg/L
Total Phosphorus	2.3 mg/L as P	2.6 mg/L as P
Total Lead	0.12 mg/L	0.14 mg/L
Total Zinc	5.7 mg/L	10 mg/L

2.2 PERFORMANCE CRITERIA

During the Guarantee Period and while conditions stated in section 2.1 are met, Veolia guarantees that the characteristics of the Facility Effluent shall meet the criteria specified in Table 2:

Table 2 Effluent Criteria

Parameter	Grab Sample Criteria	Monthly Average Criteria	Note
Total Suspended Solids	25 mg/L	15 mg/L	
Total Aluminium	0.3 mg/L	0.15 mg/L	
Total Arsenic	0.01 mg/L	0.005 mg/L	
Total Cadmium	0.00025 mg/L	0.00012 mg/L	
Total Cobalt	0.01 mg/L	0.005 mg/L	
Total Copper	0.01 mg/L	0.005 mg/L	
Total Iron	0.5 mg/L	0.25 mg/L	
Total Manganese	22 mg/L	10 mg/L	
Total Phosphorus	0.2 mg/L as P	0.1 mg/L as P	
Total Lead	0.005 mg/L	0.0025 mg/L	
Total Silver	0.0001 mg/L	No criteria	The criteria is established at 2 times the detection limit.
Dissolved Sulfates	An increase of no more than 400 mg/L through the Facility	An increase of no more than 200 mg/L through the Facility	
Sulfide	An increase of no more than 0.5 mg/L through the Facility	An increase of no more than 0.25 mg/L through the Facility	

Parameter	Grab Sample Criteria	Monthly Average Criteria	Note
Total Zinc	0.02 mg/L	0.01 mg/L	

APPENDIX E. EXTERNAL LABORATORY CERTIFICATES (ALS)

Reference Information

QC Samples with Qualifiers & Comments:

QC Type Description	Parameter	Qualifier	Applies to Sample Number(s)
Method Blank	Alkalinity, Total (as CaCO3)	B	L1628194-1, -2
Method Blank	Conductivity	B	L1628194-1, -2
Matrix Spike	Total Organic Carbon	MS-B	L1628194-1, -2
Matrix Spike	Total Organic Carbon	MS-B	L1628194-1, -2
Matrix Spike	Total Organic Carbon	MS-B	L1628194-1, -2
Matrix Spike	Orthophosphate-Dissolved (as P)	MS-B	L1628194-1, -2
Matrix Spike	Orthophosphate-Dissolved (as P)	MS-B	L1628194-1, -2
Matrix Spike	Silicon (Si)-Dissolved	MS-B	L1628194-1, -2
Matrix Spike	Silicon (Si)-Dissolved	MS-B	L1628194-1, -2

Qualifiers for Individual Parameters Listed:

Qualifier	Description
B	Method Blank exceeds ALS DQO. All associated sample results are at least 5 times greater than blank levels and are considered reliable.
DLA	Detection Limit adjusted for required dilution
DLM	Detection Limit Adjusted due to sample matrix effects.
DTC	Dissolved concentration exceeds total. Results were confirmed by re-analysis.
MS-B	Matrix Spike recovery could not be accurately calculated due to high analyte background in sample.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
ALK-TITR-VA	Water	Alkalinity Species by Titration	APHA 2320 Alkalinity

This analysis is carried out using procedures adapted from APHA Method 2320 "Alkalinity". Total alkalinity is determined by potentiometric titration to a pH 4.5 endpoint. Bicarbonate, carbonate and hydroxide alkalinity are calculated from phenolphthalein alkalinity and total alkalinity values.

BR-L-IC-N-VA	Water	Bromide in Water by IC (Low Level)	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

CARBONS-TOC-VA	Water	Total organic carbon by combustion	APHA 5310B TOTAL ORGANIC CARBON (TOC)

This analysis is carried out using procedures adapted from APHA Method 5310 "Total Organic Carbon (TOC)".

CL-IC-N-VA	Water	Chloride in Water by IC	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

COD-COL-VA	Water	Chemical Oxygen Demand by Colorimetric	APHA 5220 D. CHEMICAL OXYGEN DEMAND

This analysis is carried out using procedures adapted from APHA Method 5220 "Chemical Oxygen Demand (COD)". Chemical oxygen demand is determined using the closed reflux colourimetric method.

EC-PCT-VA	Water	Conductivity (Automated)	APHA 2510 Auto. Conduc.

This analysis is carried out using procedures adapted from APHA Method 2510 "Conductivity". Conductivity is determined using a conductivity electrode.

F-IC-N-VA	Water	Fluoride in Water by IC	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

HARDNESS-CALC-VA	Water	Hardness	APHA 2340B

Hardness (also known as Total Hardness) is calculated from the sum of Calcium and Magnesium concentrations, expressed in CaCO3 equivalents. Dissolved Calcium and Magnesium concentrations are preferentially used for the hardness calculation.

MET-D-CCMS-VA	Water	Dissolved Metals in Water by CRC ICPMS	APHA 3030B/6020A (mod)

Water samples are filtered (0.45 um), preserved with nitric acid, and analyzed by CRC ICPMS.

Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.

MET-DIS-ICP-VA	Water	Dissolved Metals in Water by ICPOES	EPA SW-846 3005A/6010B

This analysis is carried out using procedures adapted from "Standard Methods for the Examination of Water and Wastewater" published by the American Public Health Association, and with procedures adapted from "Test Methods for Evaluating Solid Waste" SW-846 published by the United States Environmental Protection Agency (EPA). The procedure involves filtration (EPA Method 3005A) and analysis by inductively coupled plasma - optical emission spectrophotometry (EPA Method 6010B).

MET-T-CCMS-VA	Water	Total Metals in Water by CRC ICPMS	EPA 200.2/6020A (mod)

Reference Information

Water samples are digested with nitric and hydrochloric acids, and analyzed by CRC ICPMS.

Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.

MET-TOT-ICP-VA Water Total Metals in Water by ICPOES EPA SW-846 3005A/6010B

This analysis is carried out using procedures adapted from "Standard Methods for the Examination of Water and Wastewater" published by the American Public Health Association, and with procedures adapted from "Test Methods for Evaluating Solid Waste" SW-846 published by the United States Environmental Protection Agency (EPA). The procedures may involve preliminary sample treatment by acid digestion, using either hotblock or microwave oven (EPA Method 3005A). Instrumental analysis is by inductively coupled plasma - optical emission spectrophotometry (EPA Method 6010B).

N-T-COL-VA Water Total Nitrogen in water by Colour APHA Method 4500-P (J) / NEMI 5735

This analysis is carried out using procedures adapted from APHA Method 4500-P (J) "Persulphate Method for Simultaneous Determination of Total Nitrogen and Total Phosphorus" and National Environmental Methods Index - Nemi method 5735.

NH3-F-VA Water Ammonia in Water by Fluorescence APHA 4500 NH3-NITROGEN (AMMONIA)

This analysis is carried out, on sulfuric acid preserved samples, using procedures modified from J. Environ. Monit., 2005, 7, 37 - 42, The Royal Society of Chemistry, "Flow-injection analysis with fluorescence detection for the determination of trace levels of ammonium in seawater", Roslyn J. Waston et al.

NH3-F-VA Water Ammonia in Water by Fluorescence J. ENVIRON. MONIT., 2005, 7, 37-42, RSC

This analysis is carried out, on sulfuric acid preserved samples, using procedures modified from J. Environ. Monit., 2005, 7, 37 - 42, The Royal Society of Chemistry, "Flow-injection analysis with fluorescence detection for the determination of trace levels of ammonium in seawater", Roslyn J. Waston et al.

NO2-L-IC-N-VA Water Nitrite in Water by IC (Low Level) EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

NO3-L-IC-N-VA Water Nitrate in Water by IC (Low Level) EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

P-T-PRES-COL-VA Water Total P in Water by Colour APHA 4500-P Phosphorus

This analysis is carried out using procedures adapted from APHA Method 4500-P "Phosphorus". Total Phosphorus is determined colourimetrically after persulphate digestion of the sample.

PH-PCT-VA Water pH by Meter (Automated) APHA 4500-H "pH Value"

This analysis is carried out using procedures adapted from APHA Method 4500-H "pH Value". The pH is determined in the laboratory using a pH electrode

It is recommended that this analysis be conducted in the field.

PH-PCT-VA Water pH by Meter (Automated) APHA 4500-H pH Value

This analysis is carried out using procedures adapted from APHA Method 4500-H "pH Value". The pH is determined in the laboratory using a pH electrode

It is recommended that this analysis be conducted in the field.

PO4-DO-COL-VA Water Diss. Orthophosphate in Water by Colour APHA 4500-P Phosphorus

This analysis is carried out using procedures adapted from APHA Method 4500-P "Phosphorus". Dissolved Orthophosphate is determined colourimetrically on a sample that has been lab or field filtered through a 0.45 micron membrane filter.

SO4-IC-N-VA Water Sulfate in Water by IC EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

TDS-VA Water Total Dissolved Solids by Gravimetric APHA 2540 C - GRAVIMETRIC

This analysis is carried out using procedures adapted from APHA Method 2540 "Solids". Solids are determined gravimetrically. Total Dissolved Solids (TDS) are determined by filtering a sample through a glass fibre filter, TDS is determined by evaporating the filtrate to dryness at 180 degrees celsius.

TKN-CALC-VA Water TKN in Water (Calculation) BC MOE LABORATORY MANUAL (2005)

Total Kjeldahl Nitrogen is a calculated parameter. Total Kjeldahl Nitrogen (calc) = Total Nitrogen - [Nitrite (as N) + Nitrate (as N)].

TSS-VA Water Total Suspended Solids by Gravimetric APHA 2540 D - GRAVIMETRIC

This analysis is carried out using procedures adapted from APHA Method 2540 "Solids". Solids are determined gravimetrically. Total Suspended Solids (TSS) are determined by filtering a sample through a glass fibre filter, TSS is determined by drying the filter at 104 degrees celsius.

TURBIDITY-VA Water Turbidity by Meter APHA 2130 "Turbidity"

This analysis is carried out using procedures adapted from APHA Method 2130 "Turbidity". Turbidity is determined by the nephelometric method.

TURBIDITY-VA Water Turbidity by Meter APHA 2130 Turbidity

Reference Information

This analysis is carried out using procedures adapted from APHA Method 2130 "Turbidity". Turbidity is determined by the nephelometric method.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

A384-2 OP WTP BST

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.
mg/kg - milligrams per kilogram based on dry weight of sample.
mg/kg wwt - milligrams per kilogram based on wet weight of sample.
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.
mg/L - milligrams per litre.
< - Less than.
D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Reference Information

QC Samples with Qualifiers & Comments:

QC Type Description	Parameter	Qualifier	Applies to Sample Number(s)
Matrix Spike	COD	MS-B	L1629665-1
Matrix Spike	Total Organic Carbon	MS-B	L1629665-1
Matrix Spike	Phosphorus (P)-Total	MS-B	L1629665-1
Matrix Spike	Total Nitrogen	MS-B	L1629665-1

Qualifiers for Individual Parameters Listed:

Qualifier	Description
DLA	Detection Limit adjusted for required dilution
DLM	Detection Limit Adjusted due to sample matrix effects.
DTC	Dissolved concentration exceeds total. Results were confirmed by re-analysis.
MS-B	Matrix Spike recovery could not be accurately calculated due to high analyte background in sample.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
ALK-TITR-VA	Water	Alkalinity Species by Titration	APHA 2320 Alkalinity

This analysis is carried out using procedures adapted from APHA Method 2320 "Alkalinity". Total alkalinity is determined by potentiometric titration to a pH 4.5 endpoint. Bicarbonate, carbonate and hydroxide alkalinity are calculated from phenolphthalein alkalinity and total alkalinity values.

BR-L-IC-N-VA	Water	Bromide in Water by IC (Low Level)	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

CARBONS-TOC-VA	Water	Total organic carbon by combustion	APHA 5310B TOTAL ORGANIC CARBON (TOC)

This analysis is carried out using procedures adapted from APHA Method 5310 "Total Organic Carbon (TOC)".

CL-IC-N-VA	Water	Chloride in Water by IC	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

COD-COL-VA	Water	Chemical Oxygen Demand by Colorimetric	APHA 5220 D. CHEMICAL OXYGEN DEMAND

This analysis is carried out using procedures adapted from APHA Method 5220 "Chemical Oxygen Demand (COD)". Chemical oxygen demand is determined using the closed reflux colourimetric method.

EC-PCT-VA	Water	Conductivity (Automated)	APHA 2510 Auto. Conduc.

This analysis is carried out using procedures adapted from APHA Method 2510 "Conductivity". Conductivity is determined using a conductivity electrode.

F-IC-N-VA	Water	Fluoride in Water by IC	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

HARDNESS-CALC-VA	Water	Hardness	APHA 2340B

Hardness (also known as Total Hardness) is calculated from the sum of Calcium and Magnesium concentrations, expressed in CaCO3 equivalents. Dissolved Calcium and Magnesium concentrations are preferentially used for the hardness calculation.

MET-D-CCMS-VA	Water	Dissolved Metals in Water by CRC ICPMS	APHA 3030B/6020A (mod)

Water samples are filtered (0.45 um), preserved with nitric acid, and analyzed by CRC ICPMS.

Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.

MET-DIS-ICP-VA	Water	Dissolved Metals in Water by ICPOES	EPA SW-846 3005A/6010B

This analysis is carried out using procedures adapted from "Standard Methods for the Examination of Water and Wastewater" published by the American Public Health Association, and with procedures adapted from "Test Methods for Evaluating Solid Waste" SW-846 published by the United States Environmental Protection Agency (EPA). The procedure involves filtration (EPA Method 3005A) and analysis by inductively coupled plasma - optical emission spectrophotometry (EPA Method 6010B).

MET-T-CCMS-VA	Water	Total Metals in Water by CRC ICPMS	EPA 200.2/6020A (mod)

Water samples are digested with nitric and hydrochloric acids, and analyzed by CRC ICPMS.

Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.

MET-TOT-ICP-VA	Water	Total Metals in Water by ICPOES	EPA SW-846 3005A/6010B

This analysis is carried out using procedures adapted from "Standard Methods for the Examination of Water and Wastewater" published by the American Public Health Association, and with procedures adapted from "Test Methods for Evaluating Solid Waste" SW-846 published by the United States Environmental Protection Agency (EPA). The procedures may involve preliminary sample treatment by acid digestion, using either hotblock or microwave oven (EPA Method 3005A). Instrumental analysis is by inductively coupled plasma - optical emission spectrophotometry (EPA Method

Reference Information

6010B).

N-T-COL-VA	Water	Total Nitrogen in water by Colour	APHA Method 4500-P (J) / NEMI 5735

This analysis is carried out using procedures adapted from APHA Method 4500-P (J) "Persulphate Method for Simultaneous Determination of Total Nitrogen and Total Phosphorus" and National Environmental Methods Index - Nemi method 5735.

NH3-F-VA	Water	Ammonia in Water by Fluorescence	APHA 4500 NH3-NITROGEN (AMMONIA)

This analysis is carried out, on sulfuric acid preserved samples, using procedures modified from J. Environ. Monit., 2005, 7, 37 - 42, The Royal Society of Chemistry, "Flow-injection analysis with fluorescence detection for the determination of trace levels of ammonium in seawater", Roslyn J. Waston et al.

NH3-F-VA	Water	Ammonia in Water by Fluorescence	J. ENVIRON. MONIT., 2005, 7, 37-42, RSC

This analysis is carried out, on sulfuric acid preserved samples, using procedures modified from J. Environ. Monit., 2005, 7, 37 - 42, The Royal Society of Chemistry, "Flow-injection analysis with fluorescence detection for the determination of trace levels of ammonium in seawater", Roslyn J. Waston et al.

NO2-L-IC-N-VA	Water	Nitrite in Water by IC (Low Level)	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

NO3-L-IC-N-VA	Water	Nitrate in Water by IC (Low Level)	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

P-T-PRES-COL-VA	Water	Total P in Water by Colour	APHA 4500-P Phosphorus

This analysis is carried out using procedures adapted from APHA Method 4500-P "Phosphorus". Total Phosphorus is determined colourimetrically after persulphate digestion of the sample.

PH-PCT-VA	Water	pH by Meter (Automated)	APHA 4500-H "pH Value"

This analysis is carried out using procedures adapted from APHA Method 4500-H "pH Value". The pH is determined in the laboratory using a pH electrode

It is recommended that this analysis be conducted in the field.

PH-PCT-VA	Water	pH by Meter (Automated)	APHA 4500-H pH Value

This analysis is carried out using procedures adapted from APHA Method 4500-H "pH Value". The pH is determined in the laboratory using a pH electrode

It is recommended that this analysis be conducted in the field.

PO4-DO-COL-VA	Water	Diss. Orthophosphate in Water by Colour	APHA 4500-P Phosphorus

This analysis is carried out using procedures adapted from APHA Method 4500-P "Phosphorus". Dissolved Orthophosphate is determined colourimetrically on a sample that has been lab or field filtered through a 0.45 micron membrane filter.

SO4-IC-N-VA	Water	Sulfate in Water by IC	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

TDS-VA	Water	Total Dissolved Solids by Gravimetric	APHA 2540 C - GRAVIMETRIC

This analysis is carried out using procedures adapted from APHA Method 2540 "Solids". Solids are determined gravimetrically. Total Dissolved Solids (TDS) are determined by filtering a sample through a glass fibre filter, TDS is determined by evaporating the filtrate to dryness at 180 degrees celsius.

TKN-CALC-VA	Water	TKN in Water (Calculation)	BC MOE LABORATORY MANUAL (2005)

Total Kjeldahl Nitrogen is a calculated parameter. Total Kjeldahl Nitrogen (calc) = Total Nitrogen - [Nitrite (as N) + Nitrate (as N)].

TSS-VA	Water	Total Suspended Solids by Gravimetric	APHA 2540 D - GRAVIMETRIC

This analysis is carried out using procedures adapted from APHA Method 2540 "Solids". Solids are determined gravimetrically. Total Suspended Solids (TSS) are determined by filtering a sample through a glass fibre filter, TSS is determined by drying the filter at 104 degrees celsius.

TURBIDITY-VA	Water	Turbidity by Meter	APHA 2130 "Turbidity"

This analysis is carried out using procedures adapted from APHA Method 2130 "Turbidity". Turbidity is determined by the nephelometric method.

TURBIDITY-VA	Water	Turbidity by Meter	APHA 2130 Turbidity

This analysis is carried out using procedures adapted from APHA Method 2130 "Turbidity". Turbidity is determined by the nephelometric method.

Reference Information

QC Samples with Qualifiers & Comments:

QC Type Description	Parameter	Qualifier	Applies to Sample Number(s)
Duplicate	Sulphide as S	DLM	L1633456-1, -2, -3, -4
Matrix Spike	Ammonia, Total (as N)	MS-B	L1633456-1, -10, -11, -2, -3, -4, -5, -6, -7, -8, -9
Matrix Spike	Total Nitrogen	MS-B	L1633456-1, -10, -11, -2, -3, -4, -5, -6, -7, -8, -9

Qualifiers for Individual Parameters Listed:

Qualifier	Description
DLA	Detection Limit adjusted for required dilution
DLM	Detection Limit Adjusted due to sample matrix effects.
MS-B	Matrix Spike recovery could not be accurately calculated due to high analyte background in sample.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
ALK-TITR-VA	Water	Alkalinity Species by Titration	APHA 2320 Alkalinity

This analysis is carried out using procedures adapted from APHA Method 2320 "Alkalinity". Total alkalinity is determined by potentiometric titration to a pH 4.5 endpoint. Bicarbonate, carbonate and hydroxide alkalinity are calculated from phenolphthalein alkalinity and total alkalinity values.

BR-L-IC-N-VA	Water	Bromide in Water by IC (Low Level)	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

CARBONS-TOC-VA	Water	Total organic carbon by combustion	APHA 5310B TOTAL ORGANIC CARBON (TOC)

This analysis is carried out using procedures adapted from APHA Method 5310 "Total Organic Carbon (TOC)".

CL-IC-N-VA	Water	Chloride in Water by IC	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

COD-COL-VA	Water	Chemical Oxygen Demand by Colorimetric	APHA 5220 D. CHEMICAL OXYGEN DEMAND

This analysis is carried out using procedures adapted from APHA Method 5220 "Chemical Oxygen Demand (COD)". Chemical oxygen demand is determined using the closed reflux colourimetric method.

EC-PCT-VA	Water	Conductivity (Automated)	APHA 2510 Auto. Conduc.

This analysis is carried out using procedures adapted from APHA Method 2510 "Conductivity". Conductivity is determined using a conductivity electrode.

F-IC-N-VA	Water	Fluoride in Water by IC	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

HARDNESS-CALC-VA	Water	Hardness	APHA 2340B

Hardness (also known as Total Hardness) is calculated from the sum of Calcium and Magnesium concentrations, expressed in CaCO3 equivalents. Dissolved Calcium and Magnesium concentrations are preferentially used for the hardness calculation.

MET-D-CCMS-VA	Water	Dissolved Metals in Water by CRC ICPMS	APHA 3030B/6020A (mod)

Water samples are filtered (0.45 um), preserved with nitric acid, and analyzed by CRC ICPMS.

Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.

MET-DIS-ICP-VA	Water	Dissolved Metals in Water by ICPOES	EPA SW-846 3005A/6010B

This analysis is carried out using procedures adapted from "Standard Methods for the Examination of Water and Wastewater" published by the American Public Health Association, and with procedures adapted from "Test Methods for Evaluating Solid Waste" SW-846 published by the United States Environmental Protection Agency (EPA). The procedure involves filtration (EPA Method 3005A) and analysis by inductively coupled plasma - optical emission spectrophotometry (EPA Method 6010B).

MET-T-CCMS-VA	Water	Total Metals in Water by CRC ICPMS	EPA 200.2/6020A (mod)

Water samples are digested with nitric and hydrochloric acids, and analyzed by CRC ICPMS.

Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.

MET-TOT-ICP-VA	Water	Total Metals in Water by ICPOES	EPA SW-846 3005A/6010B

This analysis is carried out using procedures adapted from "Standard Methods for the Examination of Water and Wastewater" published by the American Public Health Association, and with procedures adapted from "Test Methods for Evaluating Solid Waste" SW-846 published by the United States Environmental Protection Agency (EPA). The procedures may involve preliminary sample treatment by acid digestion, using either hotblock or microwave oven (EPA Method 3005A). Instrumental analysis is by inductively coupled plasma - optical emission spectrophotometry (EPA Method 6010B).

N-T-COL-VA	Water	Total Nitrogen in water by Colour	APHA Method 4500-P (J) / NEMI 5735

Reference Information

This analysis is carried out using procedures adapted from APHA Method 4500-P (J) "Persulphate Method for Simultaneous Determination of Total Nitrogen and Total Phosphorus" and National Environmental Methods Index - Nemi method 5735.

NH3-F-VA	Water	Ammonia in Water by Fluorescence	APHA 4500 NH3-NITROGEN (AMMONIA)

This analysis is carried out, on sulfuric acid preserved samples, using procedures modified from J. Environ. Monit., 2005, 7, 37 - 42, The Royal Society of Chemistry, "Flow-injection analysis with fluorescence detection for the determination of trace levels of ammonium in seawater", Roslyn J. Waston et al.

NH3-F-VA	Water	Ammonia in Water by Fluorescence	J. ENVIRON. MONIT., 2005, 7, 37-42, RSC

This analysis is carried out, on sulfuric acid preserved samples, using procedures modified from J. Environ. Monit., 2005, 7, 37 - 42, The Royal Society of Chemistry, "Flow-injection analysis with fluorescence detection for the determination of trace levels of ammonium in seawater", Roslyn J. Waston et al.

NO2-L-IC-N-VA	Water	Nitrite in Water by IC (Low Level)	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

NO3-L-IC-N-VA	Water	Nitrate in Water by IC (Low Level)	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

P-T-PRES-COL-VA	Water	Total P in Water by Colour	APHA 4500-P Phosphorus

This analysis is carried out using procedures adapted from APHA Method 4500-P "Phosphorus". Total Phosphorus is determined colourimetrically after persulphate digestion of the sample.

PH-PCT-VA	Water	pH by Meter (Automated)	APHA 4500-H "pH Value"

This analysis is carried out using procedures adapted from APHA Method 4500-H "pH Value". The pH is determined in the laboratory using a pH electrode

It is recommended that this analysis be conducted in the field.

PH-PCT-VA	Water	pH by Meter (Automated)	APHA 4500-H pH Value

This analysis is carried out using procedures adapted from APHA Method 4500-H "pH Value". The pH is determined in the laboratory using a pH electrode

It is recommended that this analysis be conducted in the field.

PO4-DO-COL-VA	Water	Diss. Orthophosphate in Water by Colour	APHA 4500-P Phosphorus

This analysis is carried out using procedures adapted from APHA Method 4500-P "Phosphorus". Dissolved Orthophosphate is determined colourimetrically on a sample that has been lab or field filtered through a 0.45 micron membrane filter.

S-DIS-ICP-VA	Water	Dissolved Sulfur in Water by ICPOES	EPA SW-846 3005A/6010B

This analysis is carried out using procedures adapted from "Standard Methods for the Examination of Water and Wastewater" published by the American Public Health Association, and with procedures adapted from "Test Methods for Evaluating Solid Waste" SW-846 published by the United States Environmental Protection Agency (EPA). The procedures may involve preliminary sample treatment by acid digestion, using either hotblock or microwave oven, or filtration (EPA Method 3005A). Instrumental analysis is by inductively coupled plasma - optical emission spectrophotometry (EPA Method 6010B).

Method Limitation: This method will not give total sulfur results for all samples. Sulfide or other volatile forms of sulfur that may be present in submitted samples, is often lost during the sampling, preservation and analysis process. The data reported as total and/or dissolved sulfur represents all non-volatile forms of sulfur present in a particular sample.

S-TOT-ICP-VA	Water	Total Sulfur in Water by ICPOES	EPA SW-846 3005A/6010B

This analysis is carried out using procedures adapted from "Standard Methods for the Examination of Water and Wastewater" published by the American Public Health Association, and with procedures adapted from "Test Methods for Evaluating Solid Waste" SW-846 published by the United States Environmental Protection Agency (EPA). The procedures may involve preliminary sample treatment by acid digestion, using either hotblock or microwave oven, or filtration (EPA Method 3005A). Instrumental analysis is by inductively coupled plasma - optical emission spectrophotometry (EPA Method 6010B).

Method Limitation: This method will not give total sulfur results for all samples. Sulfide or other volatile forms of sulfur that may be present in submitted samples, is often lost during the sampling, preservation and analysis process. The data reported as total and/or dissolved sulfur represents all non-volatile forms of sulfur present in a particular sample.

S2-T-COL-VA	Water	Total Sulphide by Colorimetric	APHA 4500-S2 Sulphide

This analysis is carried out using procedures adapted from APHA Method 4500-S2 "Sulphide". Sulphide is determined using the methlyene blue colourimetric method.

SO4-IC-N-VA	Water	Sulfate in Water by IC	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

TDS-VA	Water	Total Dissolved Solids by Gravimetric	APHA 2540 C - GRAVIMETRIC

This analysis is carried out using procedures adapted from APHA Method 2540 "Solids". Solids are determined gravimetrically. Total Dissolved Solids

Reference Information

(TDS) are determined by filtering a sample through a glass fibre filter, TDS is determined by evaporating the filtrate to dryness at 180 degrees celsius.

TKN-CALC-VA	Water	TKN in Water (Calculation)	BC MOE LABORATORY MANUAL (2005)

Total Kjeldahl Nitrogen is a calculated parameter. Total Kjeldahl Nitrogen (calc) = Total Nitrogen - [Nitrite (as N) + Nitrate (as N)].

TSS-VA	Water	Total Suspended Solids by Gravimetric	APHA 2540 D - GRAVIMETRIC

This analysis is carried out using procedures adapted from APHA Method 2540 "Solids". Solids are determined gravimetrically. Total Suspended Solids (TSS) are determined by filtering a sample through a glass fibre filter, TSS is determined by drying the filter at 104 degrees celsius.

TURBIDITY-VA	Water	Turbidity by Meter	APHA 2130 "Turbidity"

This analysis is carried out using procedures adapted from APHA Method 2130 "Turbidity". Turbidity is determined by the nephelometric method.

TURBIDITY-VA	Water	Turbidity by Meter	APHA 2130 Turbidity

This analysis is carried out using procedures adapted from APHA Method 2130 "Turbidity". Turbidity is determined by the nephelometric method.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

A384-2 OP WTP BST

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.
mg/kg - milligrams per kilogram based on dry weight of sample.
mg/kg wwt - milligrams per kilogram based on wet weight of sample.
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.
mg/L - milligrams per litre.
< - Less than.
D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Reference Information

QC Samples with Qualifiers & Comments:

QC Type Description	Parameter	Qualifier	Applies to Sample Number(s)
Matrix Spike	Total Organic Carbon	MS-B	L1634769-1, -2, -3, -4, -5, -6

Qualifiers for Individual Parameters Listed:

Qualifier	Description
DLA	Detection Limit adjusted for required dilution
DLM	Detection Limit Adjusted due to sample matrix effects.
DTC	Dissolved concentration exceeds total. Results were confirmed by re-analysis.
MS-B	Matrix Spike recovery could not be accurately calculated due to high analyte background in sample.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
ALK-TITR-VA	Water	Alkalinity Species by Titration	APHA 2320 Alkalinity

This analysis is carried out using procedures adapted from APHA Method 2320 "Alkalinity". Total alkalinity is determined by potentiometric titration to a pH 4.5 endpoint. Bicarbonate, carbonate and hydroxide alkalinity are calculated from phenolphthalein alkalinity and total alkalinity values.

BR-L-IC-N-VA	Water	Bromide in Water by IC (Low Level)	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

CARBONS-TOC-VA	Water	Total organic carbon by combustion	APHA 5310B TOTAL ORGANIC CARBON (TOC)

This analysis is carried out using procedures adapted from APHA Method 5310 "Total Organic Carbon (TOC)".

CL-IC-N-VA	Water	Chloride in Water by IC	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

COD-COL-VA	Water	Chemical Oxygen Demand by Colorimetric	APHA 5220 D. CHEMICAL OXYGEN DEMAND

This analysis is carried out using procedures adapted from APHA Method 5220 "Chemical Oxygen Demand (COD)". Chemical oxygen demand is determined using the closed reflux colourimetric method.

EC-PCT-VA	Water	Conductivity (Automated)	APHA 2510 Auto. Conduc.

This analysis is carried out using procedures adapted from APHA Method 2510 "Conductivity". Conductivity is determined using a conductivity electrode.

F-IC-N-VA	Water	Fluoride in Water by IC	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

HARDNESS-CALC-VA	Water	Hardness	APHA 2340B

Hardness (also known as Total Hardness) is calculated from the sum of Calcium and Magnesium concentrations, expressed in CaCO3 equivalents. Dissolved Calcium and Magnesium concentrations are preferentially used for the hardness calculation.

MET-D-CCMS-VA	Water	Dissolved Metals in Water by CRC ICPMS	APHA 3030B/6020A (mod)

Water samples are filtered (0.45 um), preserved with nitric acid, and analyzed by CRC ICPMS.

Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.

MET-DIS-ICP-VA	Water	Dissolved Metals in Water by ICPOES	EPA SW-846 3005A/6010B

This analysis is carried out using procedures adapted from "Standard Methods for the Examination of Water and Wastewater" published by the American Public Health Association, and with procedures adapted from "Test Methods for Evaluating Solid Waste" SW-846 published by the United States Environmental Protection Agency (EPA). The procedure involves filtration (EPA Method 3005A) and analysis by inductively coupled plasma - optical emission spectrophotometry (EPA Method 6010B).

MET-T-CCMS-VA	Water	Total Metals in Water by CRC ICPMS	EPA 200.2/6020A (mod)

Water samples are digested with nitric and hydrochloric acids, and analyzed by CRC ICPMS.

Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.

MET-TOT-ICP-VA	Water	Total Metals in Water by ICPOES	EPA SW-846 3005A/6010B

This analysis is carried out using procedures adapted from "Standard Methods for the Examination of Water and Wastewater" published by the American Public Health Association, and with procedures adapted from "Test Methods for Evaluating Solid Waste" SW-846 published by the United States Environmental Protection Agency (EPA). The procedures may involve preliminary sample treatment by acid digestion, using either hotblock or microwave oven (EPA Method 3005A). Instrumental analysis is by inductively coupled plasma - optical emission spectrophotometry (EPA Method 6010B).

N-T-COL-VA	Water	Total Nitrogen in water by Colour	APHA Method 4500-P (J) / NEMI 5735

Reference Information

This analysis is carried out using procedures adapted from APHA Method 4500-P (J) "Persulphate Method for Simultaneous Determination of Total Nitrogen and Total Phosphorus" and National Environmental Methods Index - Nemi method 5735.

NH3-F-VA	Water	Ammonia in Water by Fluorescence	APHA 4500 NH3-NITROGEN (AMMONIA)

This analysis is carried out, on sulfuric acid preserved samples, using procedures modified from J. Environ. Monit., 2005, 7, 37 - 42, The Royal Society of Chemistry, "Flow-injection analysis with fluorescence detection for the determination of trace levels of ammonium in seawater", Roslyn J. Waston et al.

NH3-F-VA	Water	Ammonia in Water by Fluorescence	J. ENVIRON. MONIT., 2005, 7, 37-42, RSC

This analysis is carried out, on sulfuric acid preserved samples, using procedures modified from J. Environ. Monit., 2005, 7, 37 - 42, The Royal Society of Chemistry, "Flow-injection analysis with fluorescence detection for the determination of trace levels of ammonium in seawater", Roslyn J. Waston et al.

NO2-L-IC-N-VA	Water	Nitrite in Water by IC (Low Level)	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

NO3-L-IC-N-VA	Water	Nitrate in Water by IC (Low Level)	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

P-T-PRES-COL-VA	Water	Total P in Water by Colour	APHA 4500-P Phosphorus

This analysis is carried out using procedures adapted from APHA Method 4500-P "Phosphorus". Total Phosphorus is determined colourimetrically after persulphate digestion of the sample.

PH-PCT-VA	Water	pH by Meter (Automated)	APHA 4500-H "pH Value"

This analysis is carried out using procedures adapted from APHA Method 4500-H "pH Value". The pH is determined in the laboratory using a pH electrode

It is recommended that this analysis be conducted in the field.

PH-PCT-VA	Water	pH by Meter (Automated)	APHA 4500-H pH Value

This analysis is carried out using procedures adapted from APHA Method 4500-H "pH Value". The pH is determined in the laboratory using a pH electrode

It is recommended that this analysis be conducted in the field.

PO4-DO-COL-VA	Water	Diss. Orthophosphate in Water by Colour	APHA 4500-P Phosphorus

This analysis is carried out using procedures adapted from APHA Method 4500-P "Phosphorus". Dissolved Orthophosphate is determined colourimetrically on a sample that has been lab or field filtered through a 0.45 micron membrane filter.

S-DIS-ICP-VA	Water	Dissolved Sulfur in Water by ICPOES	EPA SW-846 3005A/6010B

This analysis is carried out using procedures adapted from "Standard Methods for the Examination of Water and Wastewater" published by the American Public Health Association, and with procedures adapted from "Test Methods for Evaluating Solid Waste" SW-846 published by the United States Environmental Protection Agency (EPA). The procedures may involve preliminary sample treatment by acid digestion, using either hotblock or microwave oven, or filtration (EPA Method 3005A). Instrumental analysis is by inductively coupled plasma - optical emission spectrophotometry (EPA Method 6010B).

Method Limitation: This method will not give total sulfur results for all samples. Sulfide or other volatile forms of sulfur that may be present in submitted samples, is often lost during the sampling, preservation and analysis process. The data reported as total and/or dissolved sulfur represents all non-volatile forms of sulfur present in a particular sample.

S-TOT-ICP-VA	Water	Total Sulfur in Water by ICPOES	EPA SW-846 3005A/6010B

This analysis is carried out using procedures adapted from "Standard Methods for the Examination of Water and Wastewater" published by the American Public Health Association, and with procedures adapted from "Test Methods for Evaluating Solid Waste" SW-846 published by the United States Environmental Protection Agency (EPA). The procedures may involve preliminary sample treatment by acid digestion, using either hotblock or microwave oven, or filtration (EPA Method 3005A). Instrumental analysis is by inductively coupled plasma - optical emission spectrophotometry (EPA Method 6010B).

Method Limitation: This method will not give total sulfur results for all samples. Sulfide or other volatile forms of sulfur that may be present in submitted samples, is often lost during the sampling, preservation and analysis process. The data reported as total and/or dissolved sulfur represents all non-volatile forms of sulfur present in a particular sample.

S2-T-COL-VA	Water	Total Sulphide by Colorimetric	APHA 4500-S2 Sulphide

This analysis is carried out using procedures adapted from APHA Method 4500-S2 "Sulphide". Sulphide is determined using the methlyene blue colourimetric method.

SO4-IC-N-VA	Water	Sulfate in Water by IC	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

TDS-VA	Water	Total Dissolved Solids by Gravimetric	APHA 2540 C - GRAVIMETRIC

This analysis is carried out using procedures adapted from APHA Method 2540 "Solids". Solids are determined gravimetrically. Total Dissolved Solids

Reference Information

(TDS) are determined by filtering a sample through a glass fibre filter, TDS is determined by evaporating the filtrate to dryness at 180 degrees celsius.

TKN-CALC-VA	Water	TKN in Water (Calculation)	BC MOE LABORATORY MANUAL (2005)

Total Kjeldahl Nitrogen is a calculated parameter. Total Kjeldahl Nitrogen (calc) = Total Nitrogen - [Nitrite (as N) + Nitrate (as N)].

TSS-VA	Water	Total Suspended Solids by Gravimetric	APHA 2540 D - GRAVIMETRIC

This analysis is carried out using procedures adapted from APHA Method 2540 "Solids". Solids are determined gravimetrically. Total Suspended Solids (TSS) are determined by filtering a sample through a glass fibre filter, TSS is determined by drying the filter at 104 degrees celsius.

TURBIDITY-VA	Water	Turbidity by Meter	APHA 2130 "Turbidity"

This analysis is carried out using procedures adapted from APHA Method 2130 "Turbidity". Turbidity is determined by the nephelometric method.

TURBIDITY-VA	Water	Turbidity by Meter	APHA 2130 Turbidity

This analysis is carried out using procedures adapted from APHA Method 2130 "Turbidity". Turbidity is determined by the nephelometric method.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

A384-2 OP WTP BST

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.
mg/kg - milligrams per kilogram based on dry weight of sample.
mg/kg wwt - milligrams per kilogram based on wet weight of sample.
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.
mg/L - milligrams per litre.
< - Less than.
D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

APPENDIX F. MATERIAL SAFETY DATA SHEETS FOR CHEMICALS USED DURING THE TESTS

SAFETY DATA SHEET

Version 4.8
Revision Date 02/28/2015
Print Date 04/07/2015

1. PRODUCT AND COMPANY IDENTIFICATION

Product name	:	Calcium hydroxide
Product Number	:	239232
Brand	:	Sigma-Aldrich
Product Use	:	For laboratory research purposes.
Supplier	:	Sigma-Aldrich Canada Co. 2149 Winston Park Drive OAKVILLE ON L6H 6J8 CANADA
Telephone	:	+1 9058299500
Fax	:	+1 9058299292
Emergency Phone # (For both supplier and manufacturer)	:	1-800-424-9300
Preparation Information	:	Sigma-Aldrich Corporation Product Safety - Americas Region 1-800-521-8956

Manufacturer : Sigma-Aldrich Corporation
3050 Spruce St.
St. Louis, Missouri 63103
USA

2. HAZARDS IDENTIFICATION

Emergency Overview

WHMIS Classification

D2B	Toxic Material Causing Other Toxic Effects	Moderate skin irritant Moderate respiratory irritant Moderate eye irritant

GHS Classification

Skin corrosion/irritation (Category 2)
Serious eye damage/eye irritation (Category 1)
Specific target organ toxicity - single exposure (Category 3), Respiratory system
Acute aquatic toxicity (Category 3)

GHS Label elements, including precautionary statements

Pictogram

Signal word: Danger

Hazard statement(s)

H315	Causes skin irritation.
H318	Causes serious eye damage.
H335	May cause respiratory irritation.
H402	Harmful to aquatic life.

Precautionary statement(s)

P261	Avoid breathing dust/ fume/ gas/ mist/ vapours/ spray.
P280	Wear protective gloves/ eye protection/ face protection.
P305 + P351 + P338	IF IN EYES: Rinse cautiously with water for several minutes. Remove contact lenses, if present and easy to do. Continue rinsing.

HMIS Classification

Health hazard: 2

Flammability: 0
Physical hazards: 0

Potential Health Effects

Inhalation May be harmful if inhaled. May cause respiratory tract irritation.
Skin May be harmful if absorbed through skin. May cause skin irritation.
Eyes May cause eye irritation.
Ingestion May be harmful if swallowed.

3. COMPOSITION/INFORMATION ON INGREDIENTS

Formula : H_2CaO_2
Molecular weight : 74.09 g/mol

CAS-No.	EC-No.	Index-No.	Concentration
Calcium dihydroxide			
1305-62-0	215-137-3	-	<=100%

4. FIRST AID MEASURES

General advice
Consult a physician. Show this safety data sheet to the doctor in attendance.

If inhaled
If breathed in, move person into fresh air. If not breathing, give artificial respiration. Consult a physician.

In case of skin contact
Wash off with soap and plenty of water. Consult a physician.

In case of eye contact
Rinse thoroughly with plenty of water for at least 15 minutes and consult a physician.

If swallowed
Never give anything by mouth to an unconscious person. Rinse mouth with water. Consult a physician.

5. FIREFIGHTING MEASURES

Conditions of flammability
Not flammable or combustible.

Suitable extinguishing media
Use water spray, alcohol-resistant foam, dry chemical or carbon dioxide.

Special protective equipment for firefighters
Wear self-contained breathing apparatus for firefighting if necessary.

Hazardous combustion products
Hazardous decomposition products formed under fire conditions. - Calcium oxide

Explosion data - sensitivity to mechanical impact
No data available

Explosion data - sensitivity to static discharge
No data available

6. ACCIDENTAL RELEASE MEASURES

Personal precautions
Use personal protective equipment. Avoid dust formation. Avoid breathing vapours, mist or gas. Ensure adequate ventilation. Evacuate personnel to safe areas. Avoid breathing dust.

Environmental precautions
Prevent further leakage or spillage if safe to do so. Do not let product enter drains. Discharge into the environment must be avoided.

Methods and materials for containment and cleaning up
Pick up and arrange disposal without creating dust. Sweep up and shovel. Keep in suitable, closed containers for disposal.

7. HANDLING AND STORAGE

Precautions for safe handling
Avoid contact with skin and eyes. Avoid formation of dust and aerosols.
Provide appropriate exhaust ventilation at places where dust is formed.

Conditions for safe storage
Keep container tightly closed in a dry and well-ventilated place.

Keep in a dry place.

8. EXPOSURE CONTROLS/PERSONAL PROTECTION

Components with workplace control parameters

Components	CAS-No.	Value	Control parameters	Basis
Calcium dihydroxide	1305-62-0	TWA	5.000000 mg/m3	Canada. British Columbia OEL
		TWA	5.000000 mg/m3	Canada. Alberta, Occupational Health and Safety Code (table 2: OEL)
Remarks	Occupational exposure limit is based on irritation effects and its adjustment to compensate for unusual work schedules is not required			
		TWAEV	5.000000 mg/m3	Canada. Ontario OELs
		TWAEV	5.000000 mg/m3	Québec. Regulation respecting occupational health and safety, Schedule 1, Part 1: Permissible exposure values for airborne contaminants
		TWAEV	5 mg/m3	Québec. Regulation respecting occupational health and safety, Schedule 1, Part 1: Permissible exposure values for airborne contaminants
		TWA	5 mg/m3	USA. ACGIH Threshold Limit Values (TLV)
		TWA	5.000000 mg/m3	USA. ACGIH Threshold Limit Values (TLV)

Personal protective equipment

Respiratory protection
Where risk assessment shows air-purifying respirators are appropriate use a full-face particle respirator type N100 (US) or type P3 (EN 143) respirator cartridges as a backup to engineering controls. If the respirator is the sole means of protection, use a full-face supplied air respirator. Use respirators and components tested and approved under appropriate government standards such as NIOSH (US) or CEN (EU).

Hand protection
Handle with gloves. Gloves must be inspected prior to use. Use proper glove removal technique (without touching glove's outer surface) to avoid skin contact with this product. Dispose of contaminated gloves after use in accordance with applicable laws and good laboratory practices. Wash and dry hands.

Full contact
Material: Nitrile rubber
Minimum layer thickness: 0.11 mm
Break through time: 480 min
Material tested:Dermatril® (KCL 740 / Aldrich Z677272, Size M)

Splash contact
Material: Nitrile rubber

Minimum layer thickness: 0.11 mm
Break through time: 480 min
Material tested:Dermatril® (KCL 740 / Aldrich Z677272, Size M)

data source: KCL GmbH, D-36124 Eichenzell, phone +49 (0)6659 87300, e-mail sales@kcl.de, test method: EN374
If used in solution, or mixed with other substances, and under conditions which differ from EN 374, contact the supplier of the CE approved gloves. This recommendation is advisory only and must be evaluated by an industrial hygienist and safety officer familiar with the specific situation of anticipated use by our customers. It should not be construed as offering an approval for any specific use scenario.

Eye protection
Face shield and safety glasses Use equipment for eye protection tested and approved under appropriate government standards such as NIOSH (US) or EN 166(EU).

Skin and body protection
Complete suit protecting against chemicals, The type of protective equipment must be selected according to the concentration and amount of the dangerous substance at the specific workplace.

Hygiene measures
Handle in accordance with good industrial hygiene and safety practice. Wash hands before breaks and at the end of workday.

Specific engineering controls
Use mechanical exhaust or laboratory fumehood to avoid exposure.

9. PHYSICAL AND CHEMICAL PROPERTIES

Appearance

Form	powder
Colour	beige

Safety data

pH	12.4 - 12.6 at 20 °C (68 °F)
Melting point/freezing point	>= 450 °C (>= 842 °F)
Boiling point	No data available
Flash point	Not applicable
Flammability (solid, gas)	The product is not flammable.
Ignition temperature	No data available
Auto-ignition temperature	No data available
Lower explosion limit	No data available
Upper explosion limit	No data available
Vapour pressure	No data available
Density	2.24 g/mL at 25 °C (77 °F)
Water solubility	0.99 g/l at 20 °C (68 °F)
Partition coefficient: n-octanol/water	No data available
Relative vapour density	No data available
Odour	No data available
Odour Threshold	No data available
Evaporation rate	No data available

10. STABILITY AND REACTIVITY

Chemical stability
Stable under recommended storage conditions.

Possibility of hazardous reactions
No data available

Conditions to avoid
No data available

Materials to avoid
Strong acids

Hazardous decomposition products
Hazardous decomposition products formed under fire conditions. - Calcium oxide
Other decomposition products - No data available

11. TOXICOLOGICAL INFORMATION

Acute toxicity

Oral LD50
LD50 Oral - Rat - 7,340 mg/kg

Inhalation LC50
No data available

Dermal LD50
Other information on acute toxicity
No data available

Skin corrosion/irritation
Skin - Rabbit - Irritating to skin. - OECD Test Guideline 404

Serious eye damage/eye irritation
Eyes - Rabbit - Severe eye irritation - OECD Test Guideline 405

Respiratory or skin sensitisation
No data available

Germ cell mutagenicity
No data available

Carcinogenicity

IARC:	No component of this product present at levels greater than or equal to 0.1% is identified as probable, possible or confirmed human carcinogen by IARC.
ACGIH:	No component of this product present at levels greater than or equal to 0.1% is identified as a carcinogen or potential carcinogen by ACGIH.

Reproductive toxicity

No data available

Teratogenicity

No data available

Specific target organ toxicity - single exposure (Globally Harmonized System)
Inhalation - May cause respiratory irritation.

Specific target organ toxicity - repeated exposure (Globally Harmonized System)
No data available

Aspiration hazard
No data available

Potential health effects

Inhalation	May be harmful if inhaled. May cause respiratory tract irritation.
Ingestion	May be harmful if swallowed.
Skin	May be harmful if absorbed through skin. May cause skin irritation.
Eyes	May cause eye irritation.

Synergistic effects
No data available

Additional Information
RTECS: EW2800000

12. ECOLOGICAL INFORMATION

Toxicity

Toxicity to fish	LC50 - Clarias gariepinus - 33.884 mg/l - 96 h
Toxicity to daphnia and other aquatic invertebrates	EC50 - Daphnia magna (Water flea) - 49.1 mg/l - 48 h Method: OECD Test Guideline 202
Toxicity to algae	EC50 - Pseudokirchneriella subcapitata (green algae) - 184.6 mg/l - 72 h Method: OECD Test Guideline 201

Persistence and degradability
The methods for determining biodegradability are not applicable to inorganic substances.

Bioaccumulative potential
Does not bioaccumulate.

Mobility in soil
No data available

PBT and vPvB assessment
No data available

Other adverse effects

An environmental hazard cannot be excluded in the event of unprofessional handling or disposal.

Harmful to aquatic life.

No data available

13. DISPOSAL CONSIDERATIONS

Product
Offer surplus and non-recyclable solutions to a licensed disposal company.

Contaminated packaging
Dispose of as unused product.

14. TRANSPORT INFORMATION

DOT (US)
Not dangerous goods

IMDG
Not dangerous goods

IATA
Not dangerous goods

15. REGULATORY INFORMATION

WHMIS Classification

D2B	Toxic Material Causing Other Toxic Effects	Moderate skin irritant Moderate respiratory irritant Moderate eye irritant

This product has been classified in accordance with the hazard criteria of the Controlled Products Regulations and the MSDS contains all the information required by the Controlled Products Regulations.

16. OTHER INFORMATION

Text of H-code(s) and R-phrase(s) mentioned in Section 3

Further information

Hydrex

MATERIAL SAFETY DATA SHEET

1. Product and Company Identification

Product identifier	**Hydrex 3253**
Version #	02
Issue date	07-09-2014
Revision date	09-09-2014
Supersedes date	07-09-2014
CAS #	Mixture
Product use	Coagulant
Manufacturer	
Supplier	VWS Canada
Address	2000 Argentia Road, Plaza IV, Suite 430 Mississauga, ON L5N 1W1 Canada
Contact Person	Hydrex Product Specialist
Telephone	(905) 286-4846
Fax	(905) 286-0488
e-mail	vwscanada.hydrex@veoliawater.com
24-Hour Emergency telephone	+1-760-476-3962 (Code:333239)

2. Hazards Identification

Emergency overview	DANGER Corrosive. Causes skin and eye burns. Prolonged exposure may cause chronic effects.
Potential health effects	
Routes of exposure	Inhalation. Ingestion. Skin contact. Eye contact.
Eyes	Corrosive to the eyes and may cause severe damage including blindness. Causes chemical burns. Do not get this material in contact with eyes.
Skin	Causes chemical burns. Do not get this material in contact with skin.
Inhalation	May cause cancer by inhalation. May cause irritation of respiratory tract. Prolonged inhalation may be harmful. Do not breathe dust/fume/gas/mist/vapors/spray.
Ingestion	Harmful if swallowed. Ingestion causes burns of the upper digestive and respiratory tracts. Do not ingest.
Chronic effects	Frequent or prolonged contact may defat and dry the skin, leading to discomfort and dermatitis.
Signs and symptoms	Contact with this material will cause burns to the skin, eyes and mucous membranes.
Potential environmental effects	Components of this product are hazardous to aquatic life.

3. Composition / Information on Ingredients

Non-hazardous components	CAS #	Percent
IRON, WATER-SOLUBLE SALTS, N.O.S.	10028-22-5	40 - 70
Other components below reportable levels		30 - 60

4. First Aid Measures

First aid procedures

Eye contact	Immediately flush eyes with plenty of water for at least 15 minutes. If a contact lens is present, DO NOT delay irrigation or attempt to remove the lens. Continue rinsing. Get medical attention immediately.
Skin contact	Remove and isolate contaminated clothing and shoes. Immediately flush skin with plenty of water. Get medical attention immediately. For minor skin contact, avoid spreading material on unaffected skin. Wash clothing separately before reuse.

Inhalation	Move to fresh air. Oxygen or artificial respiration if needed. Do not use mouth-to-mouth method if victim inhaled the substance. Induce artificial respiration with the aid of a pocket mask equipped with a one-way valve or other proper respiratory medical device. Get medical attention, if needed.
Ingestion	IF SWALLOWED: Immediately call a POISON CENTER or doctor/physician. Never give anything by mouth to a victim who is unconscious or is having convulsions. Rinse mouth thoroughly. Do not induce vomiting without advice from poison control center. If vomiting occurs, keep head low so that stomach content doesn't get into the lungs. Induce artificial respiration with the aid of a pocket mask equipped with a one-way valve or other proper respiratory medical device.
Notes to physician	In case of shortness of breath, give oxygen. Keep victim warm. Symptoms may be delayed.
General advice	In case of shortness of breath, give oxygen. Keep victim warm. Keep victim under observation. Get medical attention if symptoms occur. Ensure that medical personnel are aware of the material(s) involved, and take precautions to protect themselves. Show this safety data sheet to the doctor in attendance. Do not use mouth-to-mouth method if victim ingested the substance.

5. Fire Fighting Measures

Flammable properties	Not flammable by WHMIS criteria.
Extinguishing media	
Suitable extinguishing media	Water fog.
Fire fighting equipment/instructions	Not available.
Explosion data	
Sensitivity to static discharge	Not available.
Sensitivity to mechanical impact	Not available.

6. Accidental Release Measures

Personal precautions	Keep unnecessary personnel away. Do not touch damaged containers or spilled material unless wearing appropriate protective clothing. Keep people away from and upwind of spill/leak.
Environmental precautions	Prevent further leakage or spillage if safe to do so. Do not contaminate water.
Methods for containment	Stop leak if you can do so without risk. Dike the spilled material, where this is possible. Prevent entry into waterways, sewer, basements or confined areas.
Methods for cleaning up	Should not be released into the environment. The product is immiscible with water and will spread on the water surface. Large Spills: Stop the flow of material, if this is without risk. Dike the spilled material, where this is possible. Cover with plastic sheet to prevent spreading. Absorb in vermiculite, dry sand or earth and place into containers. Following product recovery, flush area with water. Small Spills: Wipe up with absorbent material (e.g. cloth, fleece). Clean surface thoroughly to remove residual contamination. Never return spills in original containers for re-use. Clean up in accordance with all applicable regulations. For waste disposal, see section 13 of the MSDS.
Other information	Clean up in accordance with all applicable regulations.

7. Handling and Storage

Handling	Do not breathe dust/fume/gas/mist/vapors/spray. Do not get this material in contact with eyes. Do not get this material in contact with skin. Do not get this material on clothing. Wear personal protective equipment. Do not use in areas without adequate ventilation. Avoid prolonged exposure. Wash thoroughly after handling. Avoid release to the environment.
Storage	Store in a closed container away from incompatible materials. Keep out of the reach of children.

8. Exposure Controls / Personal Protection

Occupational exposure limits

US. ACGIH Threshold Limit Values

Components	Type	Value
IRON, WATER-SOLUBLE SALTS, N.O.S. (CAS 10028-22-5)	TWA	1 mg/m3

Canada. Alberta OELs (Occupational Health & Safety Code, Schedule 1, Table 2)

Components	Type	Value
IRON, WATER-SOLUBLE SALTS, N.O.S. (CAS 10028-22-5)	TWA	1 mg/m3

Canada. British Columbia OELs. (Occupational Exposure Limits for Chemical Substances, Occupational Health and Safety Regulation 296/97, as amended)

Components	Type	Value
IRON, WATER-SOLUBLE SALTS, N.O.S. (CAS 10028-22-5)	STEL	2 mg/m3
	TWA	1 mg/m3

Canada. Manitoba OELs (Reg. 217/2006, The Workplace Safety And Health Act)

Components	Type	Value
IRON, WATER-SOLUBLE SALTS, N.O.S. (CAS 10028-22-5)	TWA	1 mg/m3

Canada. Ontario OELs. (Control of Exposure to Biological or Chemical Agents)

Components	Type	Value
IRON, WATER-SOLUBLE SALTS, N.O.S. (CAS 10028-22-5)	TWA	1 mg/m3

Canada. Quebec OELs. (Ministry of Labor - Regulation Respecting the Quality of the Work Environment)

Components	Type	Value
IRON, WATER-SOLUBLE SALTS, N.O.S. (CAS 10028-22-5)	TWA	1 mg/m3

Biological limit values No biological exposure limits noted for the ingredient(s).

Engineering controls Ensure adequate ventilation, especially in confined areas.

Personal protective equipment

Eye / face protection Do not get in eyes. Chemical goggles are recommended.

Skin protection Do not get this material in contact with skin. Chemical resistant gloves. It may provide little or no thermal protection.

Respiratory protection Use a positive-pressure air-supplied respirator if there is any potential for an uncontrolled release, exposure levels are not known, or any other circumstances where air-purifying respirators may not provide adequate protection.

9. Physical & Chemical Properties

Appearance Not available.

Physical state Liquid.

Form Liquid

Color Red brown.

Odor Not available.

pH < 2

Vapor pressure Not available.

Vapor density Not available.

Boiling point	Not available.
Melting point/Freezing point	-0.4 °F (-18 °C)
Solubility (water)	Not available.
Specific gravity	1.45 - 1.59
Flash point	Not available.
Auto-ignition temperature	Not available.

10. Chemical Stability & Reactivity Information

Chemical stability	Material is stable under normal conditions.
Conditions to avoid	Reacts violently with strong alkaline substances. This product may react with reducing agents. Do not mix with other chemicals.
Incompatible materials	Incompatible with bases. This product may react with reducing agents.
Hazardous decomposition products	Sulfur oxides
Possibility of hazardous reactions	Hazardous polymerization does not occur.

11. Toxicological Information

Toxicological data

Product	**Species**	**Test Results**
Hydrex 3253 (CAS Mixture)		
Acute		
Dermal		
LD50	Mouse	292.9044 mg/kg estimated
Inhalation		
LC50	Guinea pig	7.2173 mg/l, 8 Hours estimated
Oral		
LD50	Rat	500 mg/kg

Components	**Species**	**Test Results**
IRON, WATER-SOLUBLE SALTS, N.O.S. (CAS 10028-22-5)		
Acute		
Dermal		
LD50	Mouse	168 mg/kg
Oral		
LD50	Rat	500 mg/kg

* Estimates for product may be based on additional component data not shown.

Acute effects	Causes burns.
Local effects	May produce corrosive solutions on contact with water.
Chronic effects	Hazardous by WHMIS criteria. Prolonged inhalation may be harmful. Prolonged exposure may cause chronic effects.
Carcinogenicity	Hazardous by WHMIS criteria. Cancer Hazard.

12. Ecological Information

Ecotoxicological data

Product		**Species**	**Test Results**
Hydrex 3253 (CAS Mixture)			
Fish	LC50	Fish	64.6086 mg/l, 96 hours estimated

Components		Species	Test Results
IRON, WATER-SOLUBLE SALTS, N.O.S. (CAS 10028-22-5)			
Aquatic			
Fish	LC50	Western mosquitofish (Gambusia affinis)	37.2 mg/l, 96 hours

* Estimates for product may be based on additional component data not shown.

Ecotoxicity Components of this product are hazardous to aquatic life. Because of the low pH of this product, it would be expected to produce significant ecotoxicity upon exposure to aquatic organisms and aquatic systems.

Environmental effects Harmful to aquatic organisms.

Persistence and degradability Not available.

Mobility in environmental media The product is immiscible with water and will spread on the water surface.

13. Disposal Considerations

Disposal instructions Collect and reclaim or dispose in sealed containers at licensed waste disposal site. Do not allow this material to drain into sewers/water supplies. Dispose in accordance with all applicable regulations.

Contaminated packaging Empty containers should be taken to an approved waste handling site for recycling or disposal.

14. Transport Information

Disclaimer	Veolia Water Solutions & Technologies is not able to anticipate all conditions under which this information and its product, or the products of other manufacturers in combination with its product, may be used. It is the user's responsibility to ensure safe conditions for handling, storage and disposal of the product, and to assume liability for loss, injury, damage or expense due to improper use and or non respect of Veolia Water Solutions & Technologies' requirement.
This data sheet contains changes from the previous version in section(s):	Composition / Information on Ingredients: Ingredients Transport Information: Material Transportation Information

MATERIAL SAFETY DATA SHEET

1. Product and Company Identification

Product identifier	**Hydrex 6183**
Version #	01
Issue date	11-07-2014
CAS #	Mixture
Product use	Wastewater Flocculant
Manufacturer	
Supplier	VWS Canada
Address	2000 Argentia Road, Plaza IV, Suite 430 Mississauga, ON L5N 1W1 Canada
Contact Person	Hydrex Product Specialist
Telephone	(905) 286-4846
Fax	(905) 286-0488
e-mail	vwscanada.hydrex@veoliawater.com
24-Hour Emergency telephone	+1-760-476-3962 (Code:333239)

2. Hazards Identification

Emergency overview	May be irritating to eyes.
Potential health effects	
Eyes	May cause eye irritation.
Skin	Health injuries are not known or expected under normal use.
Inhalation	Health injuries are not known or expected under normal use.
Ingestion	Health injuries are not known or expected under normal use.

3. Composition / Information on Ingredients

The components are not hazardous or are below required disclosure limits.

4. First Aid Measures

First aid procedures	
Eye contact	Rinse with water. Get medical attention if irritation develops and persists.
Skin contact	Rinse skin with water/shower. Get medical attention if irritation develops and persists.
Inhalation	If breathing is difficult, remove to fresh air and keep at rest in a position comfortable for breathing. Call a physician if symptoms develop or persist.
Ingestion	Rinse mouth. If ingestion of a large amount does occur, call a poison control center immediately.
General advice	If you feel unwell, seek medical advice (show the label where possible). Show this safety data sheet to the doctor in attendance.

5. Fire Fighting Measures

Flammable properties	Not flammable by WHMIS criteria. Dust accumulation from this product may present an explosion hazard in the presence of an ignition source.
Extinguishing media	
Suitable extinguishing media	Water spray, fog, CO_2, dry chemical, or alcohol resistant foam.
Protection of firefighters	
Protective equipment for firefighters	In the event of fire, wear self-contained breathing apparatus.
Fire fighting equipment/instructions	Use water spray to cool unopened containers. Dust may form an explosive mixture in the atmosphere.
Specific methods	Use water spray to cool unopened containers.

Explosion data

Sensitivity to static discharge	Not available.
Sensitivity to mechanical impact	Not available.

6. Accidental Release Measures

Personal precautions	Slippery when wet.
Environmental precautions	Prevent further leakage or spillage if safe to do so. Do not contaminate water.
Methods for cleaning up	Should not be released into the environment. Following product recovery, flush area with water. For waste disposal, see section 13 of the MSDS.

7. Handling and Storage

Handling	Avoid release to the environment. Material can be slippery when wet.
Storage	Store in a dry area. Store in closed original container at temperatures between 5°C and 30°C.

8. Exposure Controls / Personal Protection

Biological limit values	No biological exposure limits noted for the ingredient(s).

Personal protective equipment

Skin protection	Normal work clothing (long sleeved shirts and long pants) is recommended.
Respiratory protection	No personal respiratory protective equipment normally required.

9. Physical & Chemical Properties

Appearance	Not available.
Physical state	Solid.
Form	Not available.
Color	Off-white.
Odor	Not available.
pH	Not available.
Vapor pressure	Not available.
Vapor density	Not available.
Boiling point	Not available.
Melting point/Freezing point	Not available.
Solubility (water)	Not available.
Specific gravity	0.7 - 0.9
Flash point	Not available.
Auto-ignition temperature	Not available.
Ph Of 1% Solution	6 - 8.5

10. Chemical Stability & Reactivity Information

Chemical stability	Material is stable under normal conditions.
Conditions to avoid	None under normal conditions.
Incompatible materials	Not available.
Hazardous decomposition products	Upon decomposition, this product may yield oxides of nitrogen and ammonia, carbon dioxide, carbon monoxide and other low molecular weight hydrocarbons.

11. Toxicological Information

Toxicological data

Product	Species	Test Results
Hydrex 6183 (CAS Mixture)		
Acute		
Oral		
LD50	Rat	> 5000 mg/kg

* Estimates for product may be based on additional component data not shown.

Chronic effects Not expected to be hazardous by WHMIS criteria.

12. Ecological Information

Ecotoxicological data

Product		Species	Test Results
Hydrex 6183 (CAS Mixture)			
Algae	IC50	Algae	> 1000 mg/l, 72 hr
Crustacea	EC50	Daphnia	> 200 mg/l, 48 hr
Fish	LC50	Fish	> 200 mg/l, 96 hr
Aquatic			
Fish	LC50	Zebra danio (Danio rerio)	> 100 mg/l, 96 hr

* Estimates for product may be based on additional component data not shown.

Ecotoxicity Contains a substance which causes risk of hazardous effects to the environment.

Environmental effects An environmental hazard cannot be excluded in the event of unprofessional handling or disposal.

Persistence and degradability Not available.

13. Disposal Considerations

Disposal instructions Collect and reclaim or dispose in sealed containers at licensed waste disposal site. Do not allow this material to drain into sewers/water supplies. Dispose in accordance with all applicable regulations.

Contaminated packaging Empty containers should be taken to an approved waste handling site for recycling or disposal.

14. Transport Information

TDG

Not regulated as dangerous goods.

IATA

Not regulated as dangerous goods.

IMDG

Not regulated as dangerous goods.

15. Regulatory Information

Canadian regulations This product has been classified in accordance with the hazard criteria of the CPR and the MSDS contains all the information required by the CPR.

Hazards Identification: Emergency overview
Hazards Identification: Eyes

SAFETY DATA SHEET

Version 4.8
Revision Date 08/04/2014
Print Date 04/07/2015

1. PRODUCT AND COMPANY IDENTIFICATION

Product name	:	Sodium sulfide
Product Number	:	407410
Brand	:	Aldrich
Product Use	:	For laboratory research purposes.
Supplier	:	Sigma-Aldrich Canada Co. 2149 Winston Park Drive OAKVILLE ON L6H 6J8 CANADA
Telephone	:	+1 9058299500
Fax	:	+1 9058299292
Emergency Phone # (For both supplier and manufacturer)	:	1-800-424-9300
Preparation Information	:	Sigma-Aldrich Corporation Product Safety - Americas Region 1-800-521-8956

Manufacturer	:	Sigma-Aldrich Corporation 3050 Spruce St. St. Louis, Missouri 63103 USA

2. HAZARDS IDENTIFICATION

Emergency Overview

WHMIS Classification

D1B	Toxic Material Causing Immediate and Serious Toxic Effects	Toxic by ingestion
D2B	Toxic Material Causing Other Toxic Effects	Severe eye irritant
E	Corrosive Material	Corrosive
F	Dangerously Reactive Material	Unstable Reactive

GHS Classification

Self-heating substances (Category 1)
Corrosive to metals (Category 1)
Acute toxicity, Oral (Category 3)
Skin corrosion (Category 1B)
Serious eye damage (Category 1)
Acute aquatic toxicity (Category 1)

GHS Label elements, including precautionary statements

Pictogram

Signal word: Danger

Hazard statement(s)

H251	Self-heating: may catch fire.
H290	May be corrosive to metals.
H301	Toxic if swallowed.
H314	Causes severe skin burns and eye damage.
H400	Very toxic to aquatic life.

Precautionary statement(s)

P235 + P410	Keep cool. Protect from sunlight.
P273	Avoid release to the environment.

P280	Wear protective gloves/ protective clothing/ eye protection/ face protection.
P305 + P351 + P338	IF IN EYES: Rinse cautiously with water for several minutes. Remove contact lenses, if present and easy to do. Continue rinsing.
P310	Immediately call a POISON CENTER or doctor/ physician.

HMIS Classification

Health hazard: 3
Flammability: 4
Physical hazards: 0

Potential Health Effects

Inhalation	May be harmful if inhaled. Material is extremely destructive to the tissue of the mucous membranes and upper respiratory tract.
Skin	May be harmful if absorbed through skin. Causes skin burns.
Eyes	Causes eye burns.
Ingestion	Toxic if swallowed.

3. COMPOSITION/INFORMATION ON INGREDIENTS

Formula : Na_2S
Molecular Weight : 78.04 g/mol

CAS-No.	EC-No.	Index-No.	Concentration
Sodium sulphide			
1313-82-2	215-211-5	016-009-00-8	<=100%

4. FIRST AID MEASURES

General advice
Consult a physician. Show this safety data sheet to the doctor in attendance.Move out of dangerous area.

If inhaled
If breathed in, move person into fresh air. If not breathing, give artificial respiration. Consult a physician.

In case of skin contact
Take off contaminated clothing and shoes immediately. Wash off with soap and plenty of water. Take victim immediately to hospital. Consult a physician.

In case of eye contact
Rinse thoroughly with plenty of water for at least 15 minutes and consult a physician.Continue rinsing eyes during transport to hospital.

If swallowed
Do NOT induce vomiting. Never give anything by mouth to an unconscious person. Rinse mouth with water. Consult a physician.

5. FIREFIGHTING MEASURES

Conditions of flammability
Not flammable or combustible.

Suitable extinguishing media
Dry powder

Special protective equipment for firefighters
Wear self contained breathing apparatus for fire fighting if necessary.

Hazardous combustion products

Explosion data - sensitivity to mechanical impact
no data available

Explosion data - sensitivity to static discharge
no data available

6. ACCIDENTAL RELEASE MEASURES

Personal precautions
Wear respiratory protection. Avoid dust formation. Avoid breathing vapours, mist or gas. Ensure adequate ventilation. Evacuate personnel to safe areas. Avoid breathing dust.

Environmental precautions
Prevent further leakage or spillage if safe to do so. Do not let product enter drains. Discharge into the environment must be avoided.

Methods and materials for containment and cleaning up
Sweep up and shovel. Contain spillage, and then collect with an electrically protected vacuum cleaner or by wet-brushing and place in container for disposal according to local regulations (see section 13). Do not flush with water. Keep in suitable, closed containers for disposal.

7. HANDLING AND STORAGE

Precautions for safe handling
Avoid contact with skin and eyes. Avoid formation of dust and aerosols.
Provide appropriate exhaust ventilation at places where dust is formed. Keep away from sources of ignition - No smoking.

Conditions for safe storage
Keep container tightly closed in a dry and well-ventilated place.
Never allow product to get in contact with water during storage. Do not store near acids.

Recommended storage temperature: 2 - 8 °C

hygroscopic Air and light sensitive.

8. EXPOSURE CONTROLS/PERSONAL PROTECTION

Personal protective equipment

Respiratory protection
Where risk assessment shows air-purifying respirators are appropriate use a full-face particle respirator type N100 (US) or type P3 (EN 143) respirator cartridges as a backup to engineering controls. If the respirator is the sole means of protection, use a full-face supplied air respirator. Use respirators and components tested and approved under appropriate government standards such as NIOSH (US) or CEN (EU).

Hand protection
Handle with gloves. Gloves must be inspected prior to use. Use proper glove removal technique (without touching glove's outer surface) to avoid skin contact with this product. Dispose of contaminated gloves after use in accordance with applicable laws and good laboratory practices. Wash and dry hands.

Full contact
Material: Nitrile rubber
Minimum layer thickness: 0.11 mm
Break through time: 480 min
Material tested:Dermatril® (KCL 740 / Aldrich Z677272, Size M)

Splash contact
Material: Nitrile rubber
Minimum layer thickness: 0.11 mm
Break through time: 480 min
Material tested:Dermatril® (KCL 740 / Aldrich Z677272, Size M)

data source: KCL GmbH, D-36124 Eichenzell, phone +49 (0)6659 87300, e-mail sales@kcl.de, test method: EN374
If used in solution, or mixed with other substances, and under conditions which differ from EN 374, contact the supplier of the CE approved gloves. This recommendation is advisory only and must be evaluated by an industrial hygienist and safety officer familiar with the specific situation of anticipated use by our customers. It should not be construed as offering an approval for any specific use scenario.

Eye protection
Face shield and safety glasses Use equipment for eye protection tested and approved under appropriate government standards such as NIOSH (US) or EN 166(EU).

Skin and body protection
Complete suit protecting against chemicals, The type of protective equipment must be selected according to the

concentration and amount of the dangerous substance at the specific workplace.

Hygiene measures
Avoid contact with skin, eyes and clothing. Wash hands before breaks and immediately after handling the product.

Specific engineering controls
Use mechanical exhaust or laboratory fumehood to avoid exposure.

9. PHYSICAL AND CHEMICAL PROPERTIES

Appearance

Form	solid
Colour	no data available

Safety data

pH	no data available
Melting point/freezing point	Melting point/range: 950 °C (1,742 °F) - lit.
Boiling point	no data available
Flash point	not applicable
Ignition temperature	no data available
Auto-ignition temperature	The substance or mixture is classified as self heating with the category 1.
Lower explosion limit	no data available
Upper explosion limit	no data available
Vapour pressure	no data available
Density	1.86 g/mL at 25 °C (77 °F)
Water solubility	no data available
Partition coefficient: n-octanol/water	no data available
Relative vapour density	no data available
Odour	no data available
Odour Threshold	no data available
Evapouration rate	no data available

10. STABILITY AND REACTIVITY

Chemical stability
Stable under recommended storage conditions.

Possibility of hazardous reactions
no data available

Conditions to avoid
Air Avoid moisture. Light.

Materials to avoid
Oxidizing agents, Copper, Zinc

Hazardous decomposition products
Hazardous decomposition products formed under fire conditions. - Sulphur oxides, Sodium oxides
Other decomposition products - no data available

11. TOXICOLOGICAL INFORMATION

Acute toxicity

Oral LD50
LD50 Oral - rat - 246 mg/kg

Inhalation LC50
no data available

Dermal LD50
no data available

Other information on acute toxicity
no data available

Skin corrosion/irritation
no data available

Serious eye damage/eye irritation
no data available

Respiratory or skin sensitisation
no data available

Germ cell mutagenicity

Genotoxicity in vitro - mouse - lymphocyte - with and without metabolic activation - negative

Genotoxicity in vivo - mouse - male and female - negative

Carcinogenicity

IARC:	No component of this product present at levels greater than or equal to 0.1% is identified as probable, possible or confirmed human carcinogen by IARC.
ACGIH:	No component of this product present at levels greater than or equal to 0.1% is identified as a carcinogen or potential carcinogen by ACGIH.

Reproductive toxicity

no data available

Teratogenicity

no data available

Specific target organ toxicity - single exposure (Globally Harmonized System)
no data available

Specific target organ toxicity - repeated exposure (Globally Harmonized System)
no data available

Aspiration hazard
no data available

Potential health effects

Inhalation	May be harmful if inhaled. Material is extremely destructive to the tissue of the mucous membranes and upper respiratory tract.
Ingestion	Toxic if swallowed.
Skin	May be harmful if absorbed through skin. Causes skin burns.
Eyes	Causes eye burns.

Signs and Symptoms of Exposure
Material is extremely destructive to tissue of the mucous membranes and upper respiratory tract, eyes, and skin., Cough, Shortness of breath, Headache, Nausea

Synergistic effects
no data available

Additional Information

RTECS: WE1905000

12. ECOLOGICAL INFORMATION

Toxicity

Toxicity to fish	LC50 - Lepomis macrochirus (Bluegill sunfish) - 0.032 mg/l - 96 h Method: OECD Test Guideline 203
Toxicity to daphnia and other aquatic invertebrates	LC50 - Daphnia magna (Water flea) - 2.1 mg/l - 48 h
Toxicity to algae	Growth inhibition EC50 - Chlorella pyrenoidosa - 75 mg/l - 96 h

Persistence and degradability
no data available

Bioaccumulative potential

Mobility in soil
no data available

PBT and vPvB assessment
no data available

Other adverse effects

An environmental hazard cannot be excluded in the event of unprofessional handling or disposal.

Very toxic to aquatic life.

no data available

13. DISPOSAL CONSIDERATIONS

Product
Burn in a chemical incinerator equipped with an afterburner and scrubber but exert extra care in igniting as this material is highly flammable. Offer surplus and non-recyclable solutions to a licensed disposal company. Contact a licensed professional waste disposal service to dispose of this material. Dissolve or mix the material with a combustible solvent and burn in a chemical incinerator equipped with an afterburner and scrubber.

Contaminated packaging
Dispose of as unused product.

14. TRANSPORT INFORMATION

DOT (US)
UN number: 1385 Class: 4.2 Packing group: II
Proper shipping name: Sodium sulfide, anhydrous
Reportable Quantity (RQ):
Marine pollutant: No
Poison Inhalation Hazard: No

IMDG
UN number: 1385 Class: 4.2 Packing group: II EMS-No: F-A, S-J
Proper shipping name: SODIUM SULPHIDE, ANHYDROUS
Marine pollutant: No

IATA

Abstract

Ballasted flocculation is applied successfully in the water treatment industry, but the concept has not yet been subject to extended experimental studies. The use of a microsand and a polymer together to increase the weight of the flocs and the rate at which they settle is radically changing the coagulation–flocculation-settling methodology. The objective of this research is to study ballasted flocculation in the laboratory by means of a modified jar-test procedure. The first tests, conducted using a statistical approach, enabled us to identify those parameters that have a significant influence on the quality of settled water. The principal treatment parameters considered in this study were the chemical dosage, the contact times in the different basins, the pH of coagulation and the dosage of microsand. The parameters used to evaluate the quality of the settled water, and hence treatment performances, were turbidity, UV absorbance, TOC and membrane filterability. The results showed that the coagulant dosage and the coagulation pH have a preponderant effect on the variability of the quality of the settled water. By contrast, filterability as measured by the laboratory filter tests, was found to be more sensitive to coagulant and microsand dosages. It was dependent on the ratio of microsand to polymer dosage, and improved when this ratio increased. © 2002 Elsevier Science Ltd. All rights reserved.

1. Introduction

Most drinking water plants, which treat surface waters, use coagulation–flocculation-settling and filtration, with the objective of removing a large proportion of the colloids and organic matter contained in raw waters. Over the past 30 years, a number of technological innovations have led to substantial space reduction [1]. A more recent innovation involves ballasted flocculation [2]. This process, trade-named ACTIFLO®, was introduced in the 1990s. The weight of the flocs is increased by causing the attachment of grains of high-density microsand (about 2700 kg/m^3) [2]. The quality of water produced by this process is equal to or better than that of the current conventional treatment [1] and requires less space. This new treatment concept was developed by OTV, France, and is shown in Fig. 1. The process takes place in four tanks, one for each part of the process: coagulation, injection of microsand and polymer, maturation of flocs and lamella settling.

At common design conditions, the rapid mixing tank (coagulation) allows for two minutes contact time. The coagulated water then enters the injection basin where polymer and microsand are introduced simultaneously. A 2-min contact time is allowed to initiate flocs formation. Both the coagulation and injection tanks are equipped with mixers which provide high mixing intensity. The flocs grow up in the "maturation tank" which allows for 6 min contact time at a lower mixing intensity. The average design criteria of the ACTIFLO® unit is based on a 40 m^3/h/m^2 of projected surface in the

Fig. 1. Schematic description of the ACTIFLO® process.

settling tank. This corresponds to a 2–2–6–3 design, which means 2 min detention time in the coagulation tank, 2 min in the flocculation tank, 6 min of maturation and finally 3 min in the settling tank. The settled mixture of sludge and microsand is recirculated, and the microsand is separated from the sludge by the intense vortex created in a hydrocyclone and then redirected into the injection tank in order to maintain a typical microsand concentration of between 2 and 4 g/L. The microsand-free sludge is diverted into the sewer.

Since its introduction in the 1990s, the use of the ACTIFLO® process in the drinking water industry is constantly on the increase. Table 1 summarises the geographical location of full-scale plants using ACTIFLO® by the year 2000.

The aim of this study is to validate a lab-scale method that allows prediction of the performances of the ACTIFLO® process for different raw water characteristics and treatment parameters. Such a method should help reduce the number of pilot-scale or full-scale tests resulting in substantial savings during plant design and optimisation. In the present case, the laboratory method used is a jar test that is modified to take into account the sequence of addition of coagulant, microsand and polymer.

The results of these tests are used to explain the effects of a number of control parameters or treatment variables (coagulant and polymer dosages, coagulation pH, microsand dosage, contact times and temperature) on process performances. The study is divided into three stages: (1) verify whether or not the performance of the full-scale ACTIFLO® process may be accurately described by a modified jar test; (2) identify the parameters that have the most influence on ballasted flocculation and (3) study the effects of polymer and microsand dosages on process performances.

Table 1
Geographical allocation of the plants using the full-scale ACTIFLO® process in the drinking water industry at the end of 2000

Country	No. of installations	Capacity range (m^3/d)
Canada	25	720–240,000
France	19	1440–800,000
United States	25	1300–151,000
Great Britain	6	7000–270,000
Malaysia	1	1000,000
Denmark	1	2880
Turkey	2	230,000–318,000

2. Current state of knowledge

2.1. Effects of pH and temperature on coagulation–flocculation-settling

The objective of coagulation is to destabilise particles and natural organic matter in order to favour aggregation and physical removal by settling and filtration. The two most widely used types of coagulants are aluminium salts and iron salts, such as aluminium sulphate and ferric chloride. pH and temperature have a significant impact on the efficiency of the coagulation process. The rates of chemical reactions decrease as the temperature drops. In order to ensure complete reaction of the coagulants without an increase in retention time (hence tank size), pre-hydrolysed and pre-polymerised coagulants are often used at low temperature. The most common of these are polyaluminosulphate (PAS), polyaluminosulphate silicate (PASS), polyaluminochloride (PACl) and SPIC, which is a mixture of pre-hydrolysed aluminium sulphate and ferric chloride [3].

A number of researchers [4–8] have shown that each coagulant requires an optimal pH range. This zone corresponds to a minimal solubility of the coagulant, and thus to a minimal concentration of dissolved metals in the water. Some [7] have compared the performances of alum and PACl at 25°C and at 4°C, and shown that the optimal coagulation pH varies as a function of temperature for alum: pH 6 at 25°C and pH 6.8 at 4°C. According to Camp et al. [9], weak coagulation performance in cold water is also due to the poor dispersion of coagulant associated with increased water viscosity, which results in a reduction in the settling velocity of particles. These authors propose two solutions: (1) increase the mixing intensity to improve dispersion and agglomeration and (2) increase pH to minimise solubility of the coagulant.

2.2. Ballasted flocculation

The ACTIFLO® process has previously been described by Plum et al. [10]. The method has been applied to the treatment of surface water to produce drinking water around the world, the capacity of the units being as high as 800,000 m^3/d [11,1]. The process has proved to be efficient and stable enough to meet treatment standards, even under great load variations [11]. Besides coagulant, ballasted flocculation requires the addition of microsand and a polymer. The polymer helps the microsand become attached to the flocs. Dianous and Dernaucourt [12] compared the kinetics of floc formation in the conventional processes to those in the ballasted flocculation process. They showed that during ballasted flocculation the speed gradient G could be as high as 700/s without floc breakage, while in conventional flocculation it is lower by a factor of ten. Although the mixing intensity could be increased up to 700/s during floc maturation, in the full-scale systems the G values are more typically of the order of 160–200/s. This low mixing intensity proved to be adequate, besides being cost-effective. The impellers provide good mixing, which keeps all the ballasted flocs in suspension. The ballasted flocs are heavier than they are in the conventional system, which increases the settling velocity in the lamella separator. The settled ballasted sludge is pumped to a hydrocyclone, where the microsand is recovered for in-line reuse in the injection tank. The recycled flow typically makes up 6% of the total water flow treated [10]. The microsand-free sludge is sent to the sewer or to the sludge treatment units. The flocs produced in conventional treatment seem to be more fragile than ballasted flocs. Dianous and Dernaucourt [12] also showed that the time required for an 80% removal of turbidity drops from 10 to 3 min when conventional flocculation is replaced with ballasted flocculation. For optimal efficiency, they propose that the effective size of microsand be less than 160 μm, in accordance with what had previously been suggested by Guibelin [2]: 100 μm. Typical microsand dosages in the injection tank range from 2 to 4 kg/m^3.

3. Equipment and methods

3.1. Description of the modified jar-test procedure

The tests were conducted using a modified jar-test method: transparent 1-L beakers were placed on a programmable standard jar test apparatus (Phipps and Bird, Richmond, Virginia) designed to reach a rotation speed of 300 rpm and equipped with a single, flat impeller. In each beaker, the impeller was lowered in order to reach a distance less than 3 mm from the bottom of the beaker, to ensure that the ballasted flocs were maintained in suspension. The various products (coagulants, coagulation aids, microsand and polymer) were added in the same order as in the full-scale plant. The elapsed times between additions of the various chemicals were calculated to match the treatment conditions at the plants simulated. The duration of coagulation, injection and maturation for the full-scale installation was simply duplicated in the laboratory. Since lamellar settling cannot be reproduced in jar tests, preliminary tests were performed on the settling time necessary to achieve good settled water quality. The results showed that 15 s were sufficient but a 3-min settling time was kept for more practical reasons. In the laboratory procedure, stirring of the raw water in the beakers was initiated and coagulant injected at time zero. The pre-weighted amount of microsand was introduced 2 min later, along with 30–70% of the required polymer dosage (% depends on the plant simulated). After 2 min of mixing, the residual polymer (70–30%) was added and allowed a 6-min maturation. A constant mixing was maintained at 150 rpm (G in the range of 95/s) from coagulation to maturation. The mixing was then stopped and the flocs allowed to settle. Finally, the required volume of settled water was siphoned from 6 cm below the surface for analysis. Turbidity, TOC and UV were then measured directly on the collected settled water whereas a 200-mL volume of the settled water was filtered through a 0.45 μm membrane to assess membrane filterability.

3.2. Chemicals

The following coagulants and polymers were used during the tests:

- liquid alum, $Al_2(SO_4)_3 \cdot 14H_2O$ (density = 1.32–1.33; 8.3% Al_2O_3; <0.07% of insoluble substances; provided by Alcan Corp., Québec, Canada).

- Polyaluminium silicate sulphate, PASS-100®, polymerised inorganic coagulant, cationic and high molecular weight (density = 1.32–1.34; 10.0% Al_2O_3; <0.07% of insoluble substances; provided by Eaglebrook, Montreal, Canada).
- Aquafloc™ 464 (cationic, high molecular weight organic polymer provided by BetzDearborne Inc., Québec, Canada).
- Percol™ LT-27 (medium anionic organic polymer provided by Ciba Chemical Products, Québec, Canada).

Where pH adjustment was required, preliminary tests were performed in order to predetermine the amounts of acid or alkali required prior to coagulation. Two types of microsand were used, with effective diameters of 85 and 110 μm (John Meunier Inc., Quebec, Canada).

For tests on cold water, the beakers were placed in containers filled with water and ice in order to reach the desired temperature. When very low temperatures were required, the beakers were stored in a freezer at −22°C for 20 min. Under these conditions, the raw water rapidly reaches a temperature between 0°C and 1°C. The ice bath maintained the temperature of the water between 1°C and 2°C during the test.

3.3. Analytical methods

Water quality parameters were measured using standard methods [13]:

- Turbidity: method 2130 B, (Turbidimeter HACH 0-200, John Meunier Inc, Quebec, Canada).
- TOC: method 5310c, (UV-persulphate oxidation—Dorhman-180).
- UV absorbance: measured at 254 nm using a Milton Roy SPECTRONIC 1001 Plus spectrophotometer with a quartz cell having a 10-mm optical length.

Specific ultra violet absorbance (SUVA) is an index corresponding to the ratio of UV absorbance (as 1/m) to TOC (as mg C/L).

- Settled water filterability was determined using an ad hoc method. It was defined as the time required (min) for a given volume (200 mL) of settled water to pass through a 0.45 μm AcetatePlus™ filter (Fischer, Quebec, Canada) under a constant vacuum of 640 mm of mercury.

3.4. Experimental approaches

To meet the three objectives of this research, three experimental approaches were employed.

3.4.1. First approach: laboratory method to predict full-scale ballasted flocculation performance

The modified jar-test procedure (lab-scale) was used to predict ballasted flocculation (full-scale) performances. The actual dosages of chemicals and the contact times at the full-scale systems are duplicated during the laboratory tests.

3.4.2. Second approach: statistical design

The second study aimed at identifying the critical parameters in ballasted flocculation. The statistical experimental approach provides useful and critical information on ballasted flocculation and reveals the relative importance of each of the control parameters considered. Another major advantage is a significant reduction in the number of tests to be conducted, which is achieved by using a fractional factorial design. These designs are much more useful than the one-factor-at-a-time designs that are unable to detect interaction effects. However, caution must be exercised with respect to the choice of the ranges of variation of the control parameters: too wide or too narrow a range can significantly affect the impact of a control parameter on the response parameters.

The seven control parameters listed in Table 2 have been identified as possible key parameters affecting the response parameters. The main response parameters are turbidity, total organic carbon (TOC), UV absorbance and membrane filterability. The complete 2-level factorial design for seven parameters would have required $2^7 = 128$ runs. The statistical design given in Table 2 is a fractional design with coded coefficients, which are unit free $(-1, 0, 1)$ for each of the control parameters. The coefficients −1 and 1 indicate that the value tested is less than or greater than the reference coefficient coded 0. The reference values may vary for each plant; hence, the reference pH values are 6.6, 7.4 and 7.0 for plants #1, 2 and 3. For plant #1, the range of variation of pH is 6.6 ± 0.3 which means that the tests were performed at pH 6.3 (coded −1), pH 6.6 (coded 0) and pH 6.9 (coded 1). The same reasoning is applied to Runs #1 through 17 in Table 2. The 16 runs of the 2-level statistical design (−1 and 1) were replicated once (total 32 runs). Five (5) identical runs (#17) using mid-values (0) for each control parameters are added to the 32 runs, for a total 37 runs.

For each of the output response parameters Y (turbidity, TOC, UV absorbance and filterability), the data may be analysed with a second-order polynomial model:

$$Y = \beta_0 + \sum_{j=1}^{7} \beta_j x_j + \sum_{j \neq j'} \sum \beta_{jj'} x_j x_{j'}, \quad (1)$$

where x_j are the input parameters in coded form. There are several ways to present the results. A Pareto chart of the effects (main effects and interactions) gives a visual

Table 2

representation of the analysis of variance decomposition. An example of such a Pareto chart is given in Fig. 4. This type of representation allows determination of the extent to which any input parameter or group of parameters contributes to the variability of the results.

3.4.3. Third approach: a case study of a complete 4-level factorial design

From the second experimental approach, microsand and polymer were shown to be the most important parameters in their effect on the filterability of settled water as measured by laboratory membrane filter tests. In the third approach, a complete factorial design is applied to these parameters (four values each), for a total of sixteen tests.

4. Results and discussion

4.1. Impact of laboratory settling time on water quality

The modified jar-test procedure was set up to preserve the retention times in each basin. However, full-scale hydraulics and dynamics cannot be reproduced in a jar.

Fig. 2. Evolution of the turbidity of settled water versus the settling time during two duplicate tests.

Hence, preliminary tests were performed to determine the impact of the settling time on turbidity removal efficiency. To do this, turbidity was measured for various settling times and plotted in Fig. 2. Due to the practical delay in sampling, the first sample was collected after 15 s of settling; however, visual observations showed that settling of microsand weighted flocs occurred within 3–5 s following the end of mixing. Fig. 2 shows that settled water final turbidity is reached in a very short period of time; this will be confirmed in

Fig. 3. Simulations of various treatment plants using ballasted flocculation (TP = treatment plant; SW = settled water).

Table 4 where settling time never appeared as a key parameter.

4.2. Laboratory evaluation of full-scale ballasted flocculation

To evaluate the capacity of the jar-test method to predict ballasted flocculation results, the modified jar-test procedure was applied to three types of raw water from the three selected plants where ballasted flocculation technology was applied. The characteristics of these waters are described in Table 3. The same dosages and contact times applied at the plants were accurately replicated in the laboratory. The characteristics of the settled water from full-scale and the lab method are compared in Fig. 3. This comparison reveals that there is a good fit between lab results and full-scale results in terms of turbidity, UV absorbance and TOC of settled water; the percentages of variance between the two sets of results is less than 7%. It should be noted that settled water samples from full-scale settlers and from the jar test did not undergo any other treatment before turbidity, TOC, UV absorbance and membrane filterability were measured.

The aim of the laboratory method was not to recreate the mixing regime applied at full scale; this is not feasible anyway, since many factors are different: impeller design, shape of beaker, lamella in the clarifier, upflow velocity, etc. Thus in the lab method, the mixing intensity was maintained constant from coagulation through maturation to keep the simulation method simple. The results in Fig. 3 confirm that these mixing conditions were appropriate and reproduction of the exact full-scale velocity gradient was not required.

The good fit proves the effectiveness of microsand in ballasting micro-flocs, and hence in ensuring a minimum variation in the quality of settled water between the laboratory and the full-scale plant. As observed, ballasted flocculation is much less sensitive to settling time than conventional techniques, and helps explain the good correlation between full-scale operation and bench-scale experiments. In conventional systems, the occurrence of light micro-flocs in settled water makes the quality of settled water highly dependent on settling time.

As stated earlier, filterability is measured using an ad hoc method. Contrary to the other parameters, the membrane filterability results varied from 3% to 70% when applied to settled water from laboratory jar tests

versus settled water from the full-scale. However, the membrane filterability measurements, are highly repeatable when applied to the same sample. Polymer residuals or the type of turbidity found in the settled water of both scales of treatment could well explain the difference between the measurements. Particle counts and a more detailed characterisation of the settled water could help in understanding such discrepancies.

4.3. Statistical design: key input control parameters

The key input control parameters considered for each of the three treatment plants are given in Table 4.

In general, no common input parameters were found to have a decisive impact on the quality of settled water; the treatment conditions should therefore be considered site-specific. However, certain parameters appear more frequently in Table 4: alum dosage, coagulation pH, microsand dosage and coagulation time. Microsand dosage emerged to have an important impact on the settled water quality mainly on membrane filterability. In fact, the role of microsand is unquestionable since ballasted flocculation is based on the use of microsand and polymer.

4.3.1. Treatment plant #1

For plant 1, the coagulant dosage explains most of the variation in turbidity, UV absorbance and TOC. For these three response parameters, the coagulant dosage is the key parameter to control in order to improve treatment performance, independent of the raw water temperature. The seasonal variation of the impact of alum on the removal of TOC may be ascribed to temperature-variable kinetics and reaction mechanisms, and also to the different forms of organic matter according to the temperature. These results are in agreement with the usual observations made at the plant, and confirm that optimising the coagulant dosage is essential in achieving an effective clarification.

4.3.2. Treatment plant #2

The characteristics of the raw water at plant #2 are different from those at plant #1. The results obtained are also different. Here, the coagulant dosage has very little impact on the quality of the settled water.

The results on plant #2 are not very conclusive because of the characteristics of the raw water: low values of turbidity, colour and low SUVA index. The results confirm the conclusions of Van Benschoten and Edzwald [14] that a SUVA index in the order of 2 or less indicates a low effectiveness for removal of organics. In such a case, the impacts of the parameters on treatment performances are somewhat unpredictable.

4.3.3. Treatment plant #3

At plant #3, the tests were carried out during winter. The characteristics of the raw water were quite similar to those at plant #1. The SUVA index, 3 L/mg/m, is considered to be moderately high according to Van Benschoten and Edzwald [14], while turbidity and

[b] MS = microsand dosage.

alkalinity remain low. A particular feature of this plant is the use of a pre-hydrolysed coagulant, PASS-100. Statistically, almost 50% of turbidity and UV removal are explained by the coagulation time. This result at first appears surprising, since pre-hydrolysed coagulants were developed mainly for use in cold water conditions. However, the differences in the hydraulic loading rates must be considered: 30 m/h hydraulic loading rate in plant #3 versus 20 m/h for plant #1. This means that the contact times in coagulation, injection, maturation and settling tanks in plant #1 are 4, 4, 12 and 6 min versus 2.7, 2.7, 5.3 and 4 min for plant #3.

Based on Table 4, coagulation time and flocculation time are the most significant parameters at 4°C: as reaction kinetics decrease when temperature drops, a longer contact time will favour floc growth in cold water.

5. Case study of a complete 4-level factorial design: influence of microsand and polymer dosages

The principle of ballasted flocculation is rigorously associated with the use of microsand and polymer. Their impact on the quality of settled water is studied in the laboratory on the raw water from plant #1.

Four dosages of microsand were applied (1, 3, 5 and 7 mg/L). The results (Fig. 5) show that the best performances are achieved with a dosage of microsand of around 5 g/L, which confirms the conclusions derived from the statistical analysis. This dosage is higher than those commonly applied at full-scale (3 mg/L on average). According to Fig. 5, the overall benefit of increasing microsand to 5 mg/L is marginal and does not justify such additional expenses. Moreover, an excess of microsand (7 mg/L) would cause erosion of the flocs, while low dosages (1 mg/L) would result in a poor ballasting effect.

No correlation seems to exist between turbidity and membrane filterability (Figs. 5a and d). The degradation in filterability observed in the laboratory for high dosages of polymer may be caused by post-flocculation on the membranes used in the ad hoc method to assess filterability. One can hypothesise that the excess polymer would trap the coagulated particles present in the settled water by bridging them on the membrane and clog it. Under these conditions, an increase in the dosage of microsand would cause the residual polymer to be consumed and eliminated during settling and hence result in better filterability. This is the reason why for low dosages of polymer, the effect of the dosage of microsand is negligible. It should be noted that the presence of an excess of microsand does not directly degrade membrane filterability, since it is eliminated during settling. For each polymer dosage, Fig. 5d shows that membrane filterability improves with increasing

Fig. 5. Settled water quality parameters versus microsand dosage for two different polymer dosages. (a) Turbidity; (b) UV absorbance; (c) TOC; (d) Filterability.

Fig. 6. Settled water membrane filterability versus microsand/polymer ratio.

dosages of microsand. This trend is showed in Fig. 6, where filterability is plotted as a function of the microsand to polymer dosage ratio. For low ratios (below 15,000), filterability is poor, which means that a low dosage is ineffective if a high dosage of polymer is applied. However, high ratios (above 30,000) improve membrane filterability of the settled water.

6. Conclusions

This study has permitted the development of a laboratory methodology that predicts the performance of ballasted flocculation. The ballasted flocculation technology is based on the addition of microsand and polymer during coagulation–flocculation. Three drinking water production plants using the ballasted flocculation process were studied. The modified jar-test procedure was able to predict the performance of the full-scale process with good accuracy.

The use of an optimised statistical approach enables identification of the principal parameters controlling ballasted flocculation through a reduced number of experiments. Besides the microsand and polymer, the major parameters were the coagulant dosage and the pH of coagulation, as in conventional coagulation–flocculation-settling. In both conventional systems and in the ACTIFLO® process, coagulation is not very efficient for raw waters with a low SUVA (UV absorbance to TOC ratio).

No evident correlation was found between the turbidity and membrane filterability of settled water as measured by laboratory membrane filter tests. Membrane filterability is mainly affected by the microsand to polymer ratio; it improves for high ratios. Ballasted flocculation is a dynamic physical process which ensures high stability of the quality of settled water undergoing reasonable changes in operational parameters. This is likely due to the use of microsand which satisfactorily eliminates the micro-flocs that are most often responsible for degradation in the quality of settled water in conventional clarifiers.

Acknowledgements

This study was carried out in connection with the research program of the NSERC Industrial Chair on Drinking Water at the École Polytechnique de Montréal. The authors wish to thank the Chair's partners for their financial support: NSERC, City of Montreal, City of Laval, École Polytechnique de Montreal, Vivendi-Water/John Meunier Inc. and the consulting firm of Vallée Lefebvre & Ass. The study on ballasted flocculation would not have been possible without the commitment of Benoit Gagné and Jean François Beaudet (John Meunier Inc.) who gave the authors a better understanding of this new concept and access to the technology in a full-scale operation. Sincere thanks to Dr. Bernard Clément for his important contribution for the use of the statistical approach.

Appendix 2: Derivation of Modelled Nitrogen Loading Rates and Speciation

PRETIVM

Appendix 2: Derivation of Modelled Nitrogen Loading Rates and Speciation

1. Introduction

This document describes the empirical methods used to quantify nitrogen (N) loads derived from blasting activities at the Brucejack Gold Mine. These loads have been applied to the site-specific water quality model developed in support of Pretium Resources Inc.'s (Pretivm's) application to increase their ore production rate from 2700 tpd to 3800 tpd.

Ammonium nitrate (AN) explosives widely used for mining contain approximately 20% to 34% N by weight and are typically the principal source of N in mine contact waters. The inorganic N compounds in explosive mixtures are readily water-soluble and the release of N occurs from explosives loaded in boreholes and from blasting residues (Pommen, 1983; Ferguson & Leask, 1988; Revey, 1996). The explosives and blasting residues contain water-soluble N species, ammonia (representing $NH_3 + NH_4^+$; hereafter referred to as simply NH_3), nitrite (NO_2^-) and nitrate (NO_3^-), that are exported from the blast site in contact water and on blasted rock surfaces. Naturally-occurring microbially-mediated nitrification reactions can subsequently oxidize NH_3 and NO_2^- to NO_3^- in sediments and in the water column of lakes and streams.

Blasting residues originating from the use of explosives represent the dominant source of N species in Brucejack Lake. The sources of explosive-related N loads to Brucejack Lake include:

- Mine water discharged to Brucejack Lake via the Water Treatment Plant (WTP);
- Waste rock (surface and underground) deposited in the lake;
- Mill discharges (tailings solids and supernatant);
- Discharges from the contact water pond (CWP), which receives surface runoff from the mine site and recirculated effluent from the WTP, and is discharged to Brucejack Lake via the WTP; and
- Run-off from the NPAG Quarry located at the east end of Brucejack Lake.

This document describes the loading rates and proportional distributions of N species in contact water, waste rock and ore, attributable to explosives use, that are used to calculate source terms for water quality modelling. Section 2 is an overview of blasting and explosive usage at the Brucejack Gold Mine. The data and approach for deriving N loading rates are presented in Section 3, followed by a description of the data used to estimate N speciation of mine water and Brucejack Lake discharges in Section 4.

2. Overview of Explosives Usage at the Brucejack Gold Mine

2.1 Background

Blasting associated with exploration activities occurred intermittently at Brucejack Gold Mine during advanced exploration by Newhawk in the late 1980's and again beginning in 2012 following Pretivm's acquisition of the property, but ramped up in recent years with development of the mine. Blasting associated with large-scale surface excavations began with Construction in late 2015 and continued, along with pre-production underground development, through much of 2016. Further underground mine development has occurred following the mine's transition into Operations, beginning in June 2017.

Current explosives usage is dominantly associated with development of the underground mine and ore excavation. Blasting techniques, blasting products, explosive usage and explosive management have evolved at the Brucejack Gold Mine since development began. Best management practices are implemented as outlined in the Nitrogen Management Plan (Pretivm, 2016).

2.2 Blasting Methods

The release of N compounds from blasting is directly related to the quantity of explosives used for blasting a tonne of rock (also known as a powder factor, or PF) and the blasting method used. Blasting conditions (and PF) may vary daily but are generally consistent over the long-term. Assuming generally steady-state blasting conditions, N loadings from explosives use can be predicted using blasted rock quantities. The different blasting methods used at Brucejack Gold Mine include: 1) surface blasting for site preparation and quarrying; and, 2) underground blasting for mine development and ore production. The following sections summarize these methods, and the PF corresponding to each.

2.2.1 Surface Blasting

Surface blasting is typically conducted by drilling a pattern of 50 to 100 holes (0.10 to 0.14 m diameter) to a specified depth (3 m to 18 m) with 2.5 to 5 m spacing between the holes. The holes are filled with packaged AN emulsion explosives and subsequently detonated. Waste rock from the completed Construction phase surface excavation is stored in Brucejack Lake, with all waste rock placed. Construction grade rock from the NPAG Quarry is used as fill for surface construction and underground mine tunnel floors; therefore, intermittent small-scale blasting is expected to continue at the NPAG Quarry through life of mine (LOM).

The PF for surface blasting is considerably lower than for underground blasting (discussed in Section 2.2.2); therefore, N loadings in runoff and on rock surfaces at surface are expected to be low in comparison to underground. A full data evaluation of surface blasting records was not

conducted; however, review of individual blast reports indicates a PF generally between 0.15 and 0.3 kg/t.

2.2.2 Underground Blasting

Underground access tunnels are excavated using development blasting methods. This method utilizes a pattern (round) of 60 to 80 horizontal holes (0.04 m diameter) drilled into a 6 m by 5.5 m vertical rock face to a depth of 2.8 m to 4 m. The holes are filled with AN emulsion and subsequently detonated. Tunnel dimensions for drifts used to access the ore body are smaller (5 m by 5 m or 4.5 m by 5 m). The design PF for development blasting is 1.5 kg/t, an order of magnitude higher than surface blasting; therefore, N loading rates associated with underground blasting are expected to be higher.

Underground stopes (and ore) are excavated using production (long hole) blasting methods. The stope block is accessed on uppercut or undercut levels through 4.5 m by 5 m development drifts. Large diameter holes (0.09 to 0.1 m) are drilled from 5 m to 30 m depths, upward and sidelong in a radiating fan configuration, to blast a volume of rock approximately 30 m by 15 m (height and width) with a depth that varies from 10 to 30 m. The holes are filled with AN emulsion and subsequently detonated. Production blasting is also conducted from the top of stopes, with holes drilled downward. The initial design PF for production blasting is 0.7 kg/t, which is expected to contribute lower N loads to mine water and rock surfaces in comparison to development blasting.

2.3 Underground Excavation and Explosives Use

From January 2015 through January 2018, a total of 1,727,502 tonnes of rock were excavated from the underground mine using development blasting methods and 2,661,293 kg explosives (Figure 1, Table 1). Production (ore) blasting commenced in June 2017 and a total of 492,889 tonnes of ore were excavated using 388,787 kg explosives through January 2018. Mining rates increased from approximately 20,000 t/month in 2015 to 110,000 t/month in 2016 and 2017, approaching the 150,000 t/month expected with the proposed 3800 tpd production increase.

The PF for development blasting at the Brucejack Gold Mine fluctuates on a short-term (monthly) basis ranging from 0.77 to 2.93 kg/t (Figure 2, Table 1). The short-term PF is influenced by lithology and blasting conditions (*e.g.*, rock competence and presence of water). A longer period is more representative of the average blasting conditions and incorporates all short-term fluctuations, therefore the long-term PF is compared to the design PF. The long-term development blasting PF for the January 2015 through January 2018 period is 1.54 kg/t (Figure 2, Table 1). This is close to the design PF of 1.5 kg/t, which indicates the long-term explosives consumption rate is close to expected levels. The PF for production blasting is relatively consistent, with short-term (monthly) values ranging from 0.71 to 0.87 kg/t (and a long-term PF of 0.8 kg/t over the eight-month monitoring period, compared to the design PF of 0.7 kg/t). These results demonstrate

that production blasting is significantly (approximately 50%) more efficient than development blasting with respect to explosives usage.

Figure 1: Underground development (waste) and production (ore) blasted tonnages from January 2015 through January 2018.

Notes: PF = powder factor

Figure 2: Explosives use rate (powder factor, PF) for underground development (waste) and production (ore) blasting from January 2015 through January 2018.

2.4 Source Control

Concentrations of N species in mine site effluents depend on the type and quantity of explosives used for blasting and the blasting efficiency (Forsyth *et al.*, 1995; Revey, 1996). Nitrogen export is influenced by explosives handling and blasting practices, as well as site-specific conditions. The export of N at Brucejack Gold Mine is managed by implementing blasting best practices, which maximize blast efficiency through selection of appropriate explosives products and appropriate blasting methods.

To prevent loss of non-detonated explosives (*i.e.*, transfer of NH_3 and NO_3^-) to contact water, and promote efficient explosives consumption, Brucejack Gold Mine uses a water-resistant AN emulsion product (Dyno Nobel TITAN 7000). The product contains approximately 25% N almost equally distributed between NH_3 and NO_3^-. A similar packaged product is used for surface blasting, and small amounts of other packaged AN emulsion products are used for specialized applications in the underground Mine.

The consistent implementation of source control measures is achieved through regular blast practices inspections and monitoring of N species in mine water and are further described in the Brucejack Gold Mine Nitrogen Management Plan (Pretivm, 2016).

3. Nitrogen Loading Rates

3.1 Overview

For water quality modelling, it is necessary to estimate the quantity of N species that will be released to the aquatic receiving environment from blasting. N loadings from explosives use are dependent upon numerous site-specific operational factors including: explosives type, explosives usage rate (PF), quantity of rock blasted, blasting methods, blasting conditions and secondary processes that alter N speciation. Ferguson and Leask (1988) describe an empirical approach for estimating N loadings to waste rock derived from observations at surface coal mines. Similarly, site-specific monitoring records for Brucejack Gold Mine are suitable for the derivation of empirical N loading rates for underground waste and ore, surface waste and fill, mine water and surface runoff.

Brucejack Gold Mine monitoring data and excavation records are used to estimate N loading rates to contact water and to rock surfaces, expressed as total N per tonne of blasted rock. Two loading rates are developed for each term to estimate uncertainty associated with the derivation methodology: 1) Base Case, which represents reasonably expected loading rates, and 2) Upper Case, which represents an upper limit. To derive source terms for water quality modelling the N loading rates are used with the mine schedule to calculate the total N loads for model terms, these are proportioned between N species (NH_3, NO_2^- and NO_3^-) for each term according site-specific distributions (Section 4).

This section describes the derivation of N loading rates for:

- Mine water;
- Underground waste;
- Surface waste and quarry rock;
- Ore; and
- Surface runoff.

3.2 Mine Water

The mine water N loading rate is empirically derived from WTP influent mine water monitoring data and underground blasting records. Observations during Construction indicate the initial N signal from a blast is detected at the WTP influent within 12 to 24 hours. Investigations at an analogue underground mine with similar dewatering rates indicate a majority of N loadings from mine water are flushed from underground workings on the order of days to weeks following blasting (Mueller *et al.*, 2015). Under steady-state conditions (*i.e.*, relatively consistent excavation rates and explosives use) it is assumed that most of the N load introduced to mine water within a

given month is exported within the same month. Therefore, N loads exported in mine water can be correlated to tonnages excavated and expressed in terms of rock tonnage blasted.

The total nitrogen (T-N) water quality parameter provides a non-specific measure of inorganic and organically bound N and is used with WTP influent (*i.e.*, mine water) flows to estimate daily N loads in mine water, per Equation 1 and Equation 2:

Equation 1: $C_N = C_{N-1} + \frac{(D-D_1)(C_{N-2} - C_{N-1})}{D_2 - D_1}$

where:

C_N = interpolated T-N concentration (mg/L)

C_{N-1} = measured T-N concentration of sample 1 (mg/L)

C_{N-2} = measured T-N concentration of sample 2 (mg/L)

D = day for interpolated value

D_1 = sampling day of sample 1

D_2 = sampling day of sample 2

Equation 2: $L_N = C_N * Q_{WTP\ Influent} * 0.001$

where:

L_N = instantaneous total N load (kg-N/day)

C_N = T-N concentration (mg/L)

$Q_{WTP\ Influent}$ = flow rate of WTP influent (m^3/day)

The daily N loads are summed to determine the cumulative N load over distinct time periods:

1. January 2015 through July 2017 for derivation of the Base Case source term;
2. September 2015 through December 2015 for derivation of the Upper Case source term (*i.e.*, when challenging blasting conditions were encountered in the underground mine); and,
3. Monthly time steps to calculate short-term variations in the mine water loading rate.

Development and production blasting records are summed to determine the total tonnage of ore and waste rock blasted for the defined time periods, as this represents the total explosives used.

The monthly, Base Case and Upper Case mine water loading rates are determined using the cumulative N load and the total tonnage of ore and waste rock blasted for each respective monitoring period, per Equation 3:

Equation 3: $LR_N = \frac{L_{N-cumulative}}{T}$

where:

LR_N = N loading rate per tonne of blasted rock (kg-N/t)

$L_{N\text{-cumulative}}$ = cumulative total N load (kg-N)

T = Quantity of blasted rock (t) corresponding to L_N

The derived N loading rates for mine water in terms of blasted tonnage are 0.022 kg-N/t and 0.033 kg-N/t for Base Case and Upper Case, respectively. Monthly loading rates presented in Figure 3 are relatively consistent over the monitoring period and illustrate typical short-term fluctuations reflecting variations in blasting conditions. Anomalous peaks in N loadings were observed in May 2015, October 2015, October 2016 and May 2017. These short duration increases in N loadings are attributable to challenging blasting conditions (*e.g.*, blasting through water-bearing faults with significant flows at the blast face), which are known to increase the N losses from explosives.

Mine excavation records are presented in Table 1 above. Monthly WTP influent flows and N loading rates and WTP influent mine water monitoring records are presented in Table 2 and Table 3, respectively.

Figure 3: Observed monthly and derived Base Case and Upper Case N loading rates (kg-N/t) for mine water expressed in terms of blasted rock tonnages from January 2015 through January 2018; Base Case and Upper Case assumptions for modelling are indicated with dashed lines.

3.3 Waste Rock

The N loading rates for waste rock have been empirically derived using Brucejack Lake monitoring data collected during the Construction and early Operations phases. All N species arising from blasting activities at the Brucejack Gold Mine ultimately report to Brucejack Lake. The dominant N loads are derived from waste rock and tailings deposition, and, to a lesser extent, from WTP and STP discharges. Contributions from NPAG Quarry excavation are minor relative to other sources. Likewise, baseline water quality monitoring indicates there is no significant contribution of N from natural inflows.

The N budget for the lake is calculated to empirically derive N loads contributed from blasted rock submerged in Brucejack Lake. Monitoring data from WTP, STP, tailings and lake discharges are used to calculate N loads input to and exported from the lake. These data, combined with measured changes in the lake N inventory, allow estimation of N loads from waste rock surfaces using known tonnages placed in the lake. The monitoring records used for the derivation of N loading rates are summarized in Table 4.

Table 4:
Monitoring Records Used for the Derivation of Waste Rock N Loading Rates

N Load Term	Records		
	Water Quality	Volume	Tonnage
N Input			
WTP Effluent	✓	✓	
STP Effluent	✓	✓	
Tailings Discharge	✓	✓	✓
Surface Rock Placement			✓
Underground Rock Placement			✓
N Export			
Lake Outlet (BJ 3.10)	✓	✓	
N Inventory			
Lake Water Column	✓	✓	

Notes: WTP = Operations Water treatment plant; STP = Sewage Treatment Plant

The monitoring data are divided into discrete periods (time-steps) defined by the date on which the N lake inventory is measured through water column sampling at multiple depths from the surface to the bottom. The duration of each time step varies due to safety considerations; water column samples are only collected when conditions allow safe access by boat or on ice.

The input, export and inventory of N loads are calculated for each time step according to Equation 4:

Equation 4: $$L_N = \frac{C_N * V}{1000}$$

where:

L_N = N load (kg)
C_N = T-N concentration (mg/L)
V = Volume of water (m^3) for the time-step

For N inventory calculations, the lake is divided into layers (defined by the depth of each sample) and the layer volume is estimated from a previously defined fill curve (Table 5). The layer volume and the corresponding T-N concentration (Table 6) are used in Equation 4 to calculate the N load for each layer, and the sum of all the layers equals the N inventory. Observations of spatially dispersed same-day water column profiles indicate lateral mixing throughout the water column; therefore, the N inventory is assumed to account for all N input and export during each time-step. The N inventory from the previous time-step is subtracted to determine the change in N inventory for the current period.

Weekly BJ 3.10 water quality results for N species are presented in Table 7. Time-step volumes and period average T-N concentrations for WTP effluent, tailings and BJ 3.10 are summarized in Table 8 and used in Equation 4 to calculate N loads for each stream. For thickened tailings, the N load is assumed to be carried entirely in the supernatant water as the N species are highly water-soluble; therefore, tailings discharge volumes are corrected for the solids content (approximately 60% solids by weight) to determine the volume of water contained in the tailings discharge. The time-step STP effluent volumes are estimated from monthly flow records.

The derived N load terms are combined in Equation 5 to calculate the amount of N added to the lake from blasted rock surfaces. The N contributions from background input and NPAG quarry runoff are not measured and are therefore conservatively included the blasted rock N load term. The change in N inventory is adjusted for measured N input and N export to calculate the N load attributable to blasted rock surfaces.

Equation 5: $$L_{N\text{-}BR} = L_{N\text{-}\Delta I} + L_{N\text{-}LD} - L_{N\text{-}WTP} - L_{N\text{-}STP} - L_{N\text{-}T}$$

where:

$L_{N\text{-}BR}$ = N load (kg) attributed to blasted rock

$L_{N\text{-}\Delta I}$ = Change in N inventory (kg) measured in the lake water column

$L_{N\text{-}LD}$ = N load (kg) measured in the lake discharge

$L_{N\text{-}WTP}$ = N load (kg) measured in the WTP effluent

$L_{N\text{-}STP}$ = N load (kg) measured in the STP effluent (treated domestic wastewater)

$L_{N\text{-}T}$ = N load (kg) measured in tailings

Surface and underground waste rock were deposited in Brucejack Lake simultaneously for most of the period of record; however, the relative amount of underground waste rock varies from 3% to 100% of the total rock deposited. The N loads and deposition tonnages for time-steps when only underground rock was deposited in the lake (January 13, 2017 to February 1, 2018) are input to Equation 6 and Equation 7 to estimate N loading rates associated with development blasting. For time-steps when both surface and underground waste rock were deposited in the lake, the loading rates are adjusted to account for the N load from all deposited blasted rock.

Equation 6: $L_{N\text{-}BR} = L_{N\text{-}SR} + L_{N\text{-}UR}$

where:

$L_{N\text{-}BR}$ = N load (kg) attributed to all blasted rock deposited in the lake

$L_{N\text{-}SR}$ = N load (kg) attributed to surface rock deposited in the lake

$L_{N\text{-}LD}$ = N load (kg) attributed to underground rock deposited in the lake

Equation 7: $LR_N = \frac{L_N}{T}$

where:

LR_N = N loading rate per tonne of blasted rock (kg/t)

L_N = N load (kg)

T = Quantity of blasted rock (t) corresponding to L_N

Results of N loading rate derivations are summarized in Table 9. A total of 19 time-steps were defined spanning January 1, 2015 through February 1, 2018. The relative amount of underground rock varies from 3% to 100% of the total rock deposited, with predominantly underground waste rock from development blasting deposited prior to and after Construction (before September 2015 and after January 2017). The incremental N loading rate derived for time steps 2 through 4 (February 4 to August 21, 2015) and steps 13 through 19 (January 13, 2017 to Feb 1, 2018), when only development blasted underground rock was submerged in the lake, ranged from 0.049 to 0.185 kg-N/t, indicating significant N residues are present on the blasted rock (Table 9). This is likely a function of both the high explosives use rate (PF) required for development blasting and the challenging conditions (*i.e.*, flowing water) of underground blasting, reducing the efficiency of explosives consumption.

During time steps 6 and 7 (January 9 to February 25, 2016), deposition of waste rock was predominantly from surface blasting (97% and 93% of total waste rock, respectively), with surface blasting N loading rates of 0.0027 kg-N/t and 0.0037 kg-N/t, respectively, indicating the N loading from surface blasting is an order of magnitude lower than that of underground development

blasting. This is consistent with the significantly lower PF associated with surface blasting (Section 2.2.1).

Table 5:
Brucejack Lake Fill Curve

3.3.1 Underground Waste Rock

The current (2018) methodology estimates N loading rates from the lake N budget based on: 1) the observed changes in total N inventory in Brucejack Lake attributable to waste rock deposition, and 2) the tracked tonnages of waste rock deposited to the lake for the periods of January 2017 through January 2018 (Base Case) and September 2017 through January 2018 (Upper Case) (Table 9). During the period of record (January 2015 through January 2018), surface waste rock and underground waste rock were deposited concurrently to Brucejack Lake, but at varying proportions over time. The N loading rates for both surface and underground rock were derived to fully account for the incremental change in the lake N inventory between each monitoring event.

The time step N loading rates for development blasting are shown in Figure 4, and range from 0.030 to 0.185 kg-N/t. The long-term N loading rate (January 13, 2017 through February 1, 2018) attributed to underground waste is estimated to be 0.137 kg-N/t (Table 9, Figure 4), and this value is rounded up to 0.14 kg-N/t to represent the Base Case. The short-term N loading rate of 0.171 mg-N/t (September 3, 2017 through February 1, 2018) is rounded to 0.17 kg-N/t for the Upper Case. Waste rock deposited in Brucejack Lake is assumed to instantaneously release 100% of the N load at the time of deposition. The mine development blasting long-term PF was 1.54 kg/t of blasted rock (Section 2.2.2); it is assumed that explosives use rate will remain similar for the LOM.

Figure 4: Inferred N loading rate for waste rock produced by underground development blasting from January 1, 2015 through February 1, 2018; Base Case and Upper Case assumptions used for modelling are indicated with dashed lines.

3.3.2 Surface Waste Rock

Approximately 1,500 kt of waste rock was blasted and excavated from the Mine Site surface to develop the site for various facilities including the Mill, Camp and CWP in preparation for Operations. Full-scale construction of the Mine Site was initiated in September 2015 and continued during 2016, with the majority of excavation occurring in Q1 and Q2 of 2016 (Table 9). Excavated NPAG Quarry rock was used as fill for pad and road construction.

The current (2018) modelling approach assigned a N loading rate that was estimated from: 1) the observed changes in the lake total N inventory attributable to waste rock deposition, and 2) the tracked tonnages of waste rock deposited to Brucejack Lake for the period of January 2015 through December 2016. Surface waste rock and underground waste rock were deposited concurrently to Brucejack Lake, but at varying proportions over time; therefore, N load rates were derived for both surface and underground materials to fully account for the incremental change in the lake N inventory for each time step. Mine construction was completed in early 2017; therefore, surface blasting ceased, and no surface waste rock was deposited to the lake after December 2016.

Figure 5 shows the time-step N loading rates for surface blasting range from 0.0027 to 0.0055 kg-N/t. The long-term (January 9, 2016 to January 12, 2017) N loading rate for surface blasted waste rock is 0.004 kg-N/t (Table 9). The modelled surface waste rock loading rates are conservatively rounded up to 0.005 kg-N/t for the Base Case and 0.008 kg-N/t for the Upper Case. Further, 100% of the loads are assumed to be instantaneously released to the lake. The PF for surface blasting is assumed to be 0.3 kg/t, the upper range of observed values (Section 2.2.1).

Figure 5: Inferred N loading rate for waste rock produced by surface blasting from January 1, 2015 to January 12, 2017; Base Case and Upper Case assumptions for modelling are indicated with dashed lines.

3.4 Ore

The ore N loading rate is derived from monitoring data collected at the Semi-Autogenous Grinding (SAG) Mill from June 2017 through February 2018. Within the Mill circuit, the SAG Mill was identified as the best monitoring location for the purposes of developing the nitrogen ore loading rate because: 1) all crushed ore is first processed through the SAG Mill, and 2) the SAG Mill effluent quality is solely influenced by ore throughput and the quality of the influent process water. The inorganic N species (NH_3, NO_2^- and NO_3^-) are water soluble and considering the grinding and mixing that occurs in the SAG Mill, it is assumed that all N residues on the ore are transferred to the liquid phase of the SAG effluent slurry. Process water input and SAG effluent locations are accessible for sampling upstream and downstream of the SAG Mill, respectively.

The N load attributable to the ore is derived from water quality data, and instantaneous ore and process water feed rates. The change in the process water T-N concentration is calculated for each sampling event, as per Equation 8:

Equation 8: $\Delta C_N = C_{N-SAG\ Mill\ Discharge} - C_{N-SAG\ Mill\ Influent}$

where:

ΔC_N = Change in T-N concentration (mg/L)

$C_{N\text{-}SAG\ Mill\ Discharge}$ = T-N concentration of SAG Mill discharge (mg/L)

$C_{N\text{-}SAG\ Mill\ Influent}$ = T-N concentration of SAG Mill influent (mg/L)

Ore and process water feed rates are used to calculate the instantaneous total N loading rates, as per Equation 9:

Equation 9: $L_N = \Delta C_N * \frac{Q_{SAG\ Mill\ Influent}}{F_{SAG\ Mill\ Ore}} * 0.001$

where:

L_N = N load (kg)

ΔC_N = Change in T-N concentration (mg/L)

$Q_{SAG\ Mill\ Influent}$ = Flow rate of SAG Mill Influent (m^3/hr)

$F_{SAG\ Mill\ Ore}$ = SAG Mill ore feed rate (t/hr)

The instantaneous N loading rate calculated for each of the 25 sampling events ranged from 0.005 to 0.056 kg-N/t (Figure 6, Table 10). Overall, the observed loading rates are significantly lower than for development waste rock blasting, consistent with the lower PF observed for production blasting (Section 2.2.2 and Section 2.3). The monitoring of the SAG Mill process represents discrete instantaneous measurements of N loads on ore, therefore the 75th and 90th percentiles of this SAG Mill dataset (June 12, 2017 through September 24, 2017) were conservatively used to

represent production blasted ore N loading rates for the Base Case (0.028 kg-N/t) and Upper Case (0.054 kg-N/t), respectively. Figure 6 shows the discrete total N loading rates for ore in comparison to the Base Case and Upper Case loading rates. Table 10 presents the monitoring data and calculated results for the derivation of the ore loading rate.

Figure 6: Total N loading rates for ore excavated using production (long-hole) blasting measured at the SAG mill on weekly (June to October 2017) and monthly (November 2017 to February 2018) frequencies; Base Case and Upper Case assumptions for modelling are indicated with dashed lines.

3.5 Surface Runoff

Mine Site runoff within the contact water management area is collected in the CWP and pumped to the WTP for treatment, ultimately reporting the Brucejack Lake via the WTP effluent or tailings slurry discharge. The Mine Site runoff source term includes CWP catchment drainage from all exposed blasted rock surfaces and from NPAG Quarry fill used for the construction of pads and

roads. The NPAG Quarry is located near the southeast end of Brucejack Lake, with runoff from this area reporting directly to Brucejack Lake. Drainage from NPAG Quarry surface fill used for road and pad construction outside the contact water management area also reports directly to Brucejack Lake.

Surface runoff from blasted and/or filled areas is generally not observed. Consequently, empirical methods are not available for derivation of N loading rates. Only a small proportion of the excavation blasting residues report to runoff (*i.e.*, the majority remains on the waste rock surfaces) as has been observed elsewhere (Ferguson & Leask, 1988; Cameron *et al.*, 2007; Baily *et al.*, 2013). Infiltration and rinsing of surfaces filled with NPAG Quarry rock is limited by building coverage, the water shedding characteristics of road and pad surfacing, and by winter snow removal, which reduces road, and mill and camp pad runoff during the spring melt period. Therefore, considering literature values and site characteristics, the surface blasting N loading rate to runoff is estimated to be a proportion (25%) of the loading rates derived for surface waste rock (Section 3.3.2), at 0.001 kg-N/t and 0.002 kg-N/t of blasted rock for Base Case and Upper Case, respectively.

Field observations described in the literature indicate surface runoff N loads from rock piles can be released over several years. However, considering the small magnitude of these N source terms compared to other sources, the N source term derivations are simplified to assume all surface and Mine Site runoff N loads report to Brucejack Lake the same year the surface rock is excavated and placed.

4. N Speciation

4.1 Overview

At Brucejack Gold Mine the N species (NH_3, NO_2^- and NO_3^-) originate primarily from explosives in which N is approximately equally distributed between NH_3 and NO_3^-. Blasting residuals release NH_3, NO_2^- and NO_3^- to contact water and rock surfaces at the blast location, the NO_2^- originates as an explosion by-product. Near the blast location NH_3 and NO_3^- are the dominant N species, however enrichment of NO_3^- as a proportion of the total N is generally observed in downstream mine-influenced waters. The proportional distribution of N species can be affected by secondary processes such as naturally occurring microbially-mediated reactions that oxidize NH_3 and NO_2^- to NO_3^-, referred to as nitrification (Hall, 1981; Ward *et al.*, 2011). These processes are variable and subject to complex environmental influences, therefore endpoints of nitrification processes based on site monitoring data are used to conservatively model the distribution of NH_3, NO_2^- and NO_3^- as a proportion of the modelled N loads.

This section summarizes the N species distributions observed in mine and lake waters, and the methods used to estimate the distributions used for water quality modeling. The N speciation applied to N source terms and modelled lake discharge (BJ 3.10) water quality are described.

4.2 Mine Water N Speciation

Mine water quality is monitored at the influent to the WTP. The inorganic N species (NH_3, NO_2^- and NO_3^-) are introduced to mine water through the dissolution of blasting residues at blast sites. Total nitrogen (T-N) is also monitored and provides a measure of N from all inorganic and organic compounds that contain N. The relative proportions of N species in mine water, shown in Figure 7, are derived by dividing the parameter concentration (as mg-N/L) by the sum of NH_3, NO_2^- and NO_3^- (as mg-N/L) and converting the ratio to a percentage. The proportion of T-N is compared to the sum of the N species to confirm that the N budget in the mine water is balanced. Monitoring data indicate that the sum of the measured inorganic N species is generally consistent with measured T-N values, indicating that N is predominantly present as inorganic species in mine water.

Figure 7: Mine water distribution of individual N species and total nitrogen as a proportion of the sum of the inorganic N species, from January 4, 2016 through February 4, 2018.

As shown in Figure 7, the N species distributions are relatively stable for the period of record, with NO_3^- proportions ranging between approximately 65 to 76%, the proportions of NH_3 typically between 21 to 32% and NO_2^- between 2 to 11%. Median and maximum values shown in Table 11

are calculated using the January 4, 2016 through February 4, 2018 data (Table 3). The median values from the data set are normalized to 100% through recalculation of the relative proportions over the sum of the median values. Monitoring data support the mine water N species distribution derived for the November 2016 water quality model update (Lorax, 2016). Therefore, the assumed proportions for the 2016 model are carried forward for current modelling of N species distribution for all N source terms (66.0%, 5.2%, 28.8% for NO_3^-, NO_2^- and NH_3, respectively).

Table 11:
Summary of N Species Distributions in Mine Water as a Proportion of the Sum of Species

Basis of N Species Distribution	NO_3^-	NO_2^-	NH_3
2016 water quality model update (Lorax, 2016)	66.0%	5.2%	28.8%
Jan 4, 2016 – Feb 4, 2018; median	68.9%	5.3%	25.7%
Jan 4, 2016 – Feb 4, 2018; median (normalized)	68.0%	5.2%	25.4%

4.3 Brucejack Lake Water

Brucejack Lake receives N loads that originate from mining activities at the Brucejack Gold Mine through surface runoff, STP effluent discharge, WTP effluent discharge, tailings discharge and waste rock deposition. The dominant N loads are from WTP effluent, tailings and waste rock. The N loads are dissolved and mixed into lake water prior to discharge from the lake outlet (BJ 3.10) as the inorganic N species (*i.e.*, NH_3, NO_2^- and NO_3^-). Vertical mixing is promoted year-round by waste rock deposition, although seasonal stratification constrains the mixing to the deeper waters except during late Spring and early Autumn lake turnover events when mixing extends to the surface waters. The entire lake volume is discharged every two to three years.

Nitrifying microbes have been previously detected in mine slimes, mine water and lake water as described in the November 2016 water quality model update (Lorax, 2016). Microbially-mediated nitrification processes occur naturally in cold water lakes and can control the distribution of nitrogen species in the water column (Sterner *et al.*, 2007) typically promoting an increase in the proportion of N in the form of NO_3^-. Nitrification rates in these environments are affected by temperature, nutrient levels, substrate and other environmental factors (Dvir & Neori, 1999; Kaplan *et al.*, 2000; Gerardi, 2002; Ward *et al.*, 2011; Bristow *et al.*, 2015) which may cause variations of the relative proportions of NH_3, NO_2^- and NO_3^- in the water column. Temporary decoupling of the rates of oxidation of N species by microbial communities can also occur, leading to temporary accumulation of NH_3 or NO_2^-. The microbially mediated oxidation of NH_3 to NO_2^- is considered to be the rate-limiting step for overall nitrification (Ginestet *et al.*,1998).

Monitoring data from January 4, 2016 through January 29, 2018 indicate that the proportion of NO_3^- observed in lake discharge (BJ 3.10) ranges from 92.8 to 99.7%, whereas NH_3 and NO_2^- range

from 0.2 to 7.0% and 0.1 to 2.3%, respectively (Figure 8). The proportion of T-N relative to the sum of the N species indicates inorganic N species fully account for all N loads exported from the lake. The enrichment of NO_3^- at BJ 3.10 relative to mine water (Section 4.2) is inferred to reflect nitrification (naturally occurring NH_3 and NO_2^- oxidation) in the Brucejack Lake water column. Recent monitoring data indicate the proportion of N as NH_3 has increased at the lake outlet suggesting the nitrification rate in the lake is not keeping pace with the NH_3 loads added to the lake. The proportion of NO_2^- has remained stable indicating nitrification is occurring, however the proportional build-up of NH_3 suggests that the nitrification rate is limited by the microbially-mediated oxidation of NH_3 to NO_2^-.

Figure 8: Brucejack Lake outlet (BJ 3.10) N species and total nitrogen distribution as a proportion of the sum of the species, from January 4, 2016 through February 4, 2018.

The BJ 3.10 median and maximum values shown in Table 12 are calculated using monitoring data collected between January 4, 2016 and January 29, 2018 (Table 7). For reference, the distributions used in the 2016 revision of the water quality model (Lorax, 2016) are also included in Table 12. The normalized N speciation at BJ 3.10 derived from median values is similar to the 2016 water quality model assumptions (Lorax, 2016), however the median values do not reflect the recent increase in the proportion of NH_3 (Figure 8).

Table 12:
Summary of N Species Distribution at Brucejack Lake Outlet (BJ 3.10)

Basis of N Species Distribution	NO_3^-	NO_2^-	NH_3
2016 Water Quality Model Update	94.0%	2.0%	4.0%
Jan 4, 2016 – Jan 29, 2018; median	98.5%	0.3%	1.0%
Jan 4, 2016 – Jan 29, 2018; median (normalized)	98.9%	0.3%	1.0%
Jan 4, 2016 – Jan 29, 2018; maximum	99.7%	2.3%	7.0%

A recent investigation of the lake water column indicates NH_3 constitutes a significant proportion of the N at all depths. Lake water column samples collected on February 1, 2018 monitored eight depth intervals ranging from 2 to 76 m (Figure 9). The relative proportion of NH_3 increases from 6.4 to 18.2%, from the 2 to 76 m depths, respectively. The proportion of NH_3 in the surface water is similar to observations at BJ 3.10, consistent with the expectation that lake waters from the stratified surface layer are discharging at the lake outlet. Lake stratification is confirmed by a thermocline measured at approximately 7 m depth and is illustrated by the abrupt increase in the proportion of NH_3 from the 7 m depth (6.5%) to the 15 m depth (9.8%). The proportion of NO_2^- is consistently low (generally < 1%) throughout the water column. The observation of increasing proportions of NH_3 in deeper waters coupled with the consistent proportion of NO_2^- at all depths indicates that nitrification is occurring, and that NH_3 oxidation is the rate-limiting step for nitrification processes at all depths in the lake. As described previously, these data suggest that the nitrification rate in the lake is not keeping pace with the NH_3 loads added to the lake, leading to NH_3 accumulation in the water column.

As noted previously, microbially-mediated nitrification rates are influenced by seasonal factors such as water temperature (*i.e.*, nitrification rates decrease with decreasing temperature); therefore, lower rates may be observed in the lake water during ice-covered winter conditions. Low temperatures reduce microbial population growth rates, thereby increasing the lag time for microbial community response to increased NH_3 concentration. This lag time would be reflected by a temporary accumulation of NH_3 that peaks and then decreases as microbial populations (and the nitrification rate) increase. The recent monitoring data indicate that nitrification is occurring; however, the present nitrification rate is insufficient to keep pace with the rate of NH_3 loading to the lake and consequently, NH_3 is accumulating in the deeper lake waters. If nitrification rates remain low, it is possible that the proportion of NH_3 at the lake outlet could approach the distribution of N loads added to the lake, principally from WTP effluent, tailings and waste rock.

Figure 9: Brucejack Lake water column N species and total nitrogen distribution as a proportion of the sum of the species as measured on February 1, 2018.

To address the uncertainty associated with variable nitrification rates, N species distribution endpoints are used to model N species concentrations at the lake outlet (BJ 3.10). For high rates of nitrification, it is assumed that NH_3 is substantially converted to NO_3^-; whereas for low nitrification rates, is it assumed that NH_3 behaves conservatively in the lake. Under both nitrification scenarios, NO_2^- is assumed to represent a small proportion of the total N at the lake outlet. For modelling, the NO_3^- and NO_2^- are assumed to be 99.7% and 2.7% of the total N, respectively (Table 12, BJ 3.10 maximum values), whereas for NH_3 32.2% is assumed (Table 11, maximum value). Although these proportions sum to 134.6% of the total N modelled for BJ 3.10, this approach is considered to conservatively represent both low and high rates of nitrification. The nitrification rates and the associated N distribution in Brucejack Lake will continue to be monitored throughout LOM to validate the modelling assumptions.

Notes:
BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Concentrations that exceed long-term guidelines are shown as underlined font.
Concentrations that exceed short-term guidelines are shown as bold font.
Concentrations that exceed the discharge limit are shaded in grey.
Hardness dependent guidelines are calculated using the baseline median hardness of 28 mg/L as CaCO3.
Ammonia guidelines assume a pH of 8.0 and temperature of 15°C.
Chromium guideline is for Cr(VI).

Notes:
BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Concentrations that exceed long-term guidelines are shown as underlined font.
Concentrations that exceed short-term guidelines are shown as bold font.
Concentrations that exceed the discharge limit are shaded in grey.
Hardness dependent guidelines are calculated using the baseline median hardness of 28 mg/L as CaCO3.
Ammonia guidelines assume a pH of 8.0 and temperature of 15°C.
Chromium guideline is for Cr(VI).

Notes:
BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Concentrations that exceed long-term guidelines are shown as underlined font.
Concentrations that exceed short-term guidelines are shown as bold font.
Concentrations that exceed the discharge limit are shaded in grey.
Hardness dependent guidelines are calculated using the baseline median hardness of 28 mg/L as CaCO3.
Ammonia guidelines assume a pH of 8.0 and temperature of 15°C.
Chromium guideline is for Cr(VI).

Discharge Limit	1.0	12	0.24	-	-	-	-	0.050	-	-	-	-	-	-	0.000050	-	-	-	-	-	-	-	-	-

Notes:
BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Concentrations that exceed long-term guidelines are shown as underlined font.
Concentrations that exceed short-term guidelines are shown as bold font.
Concentrations that exceed the discharge limit are shaded in grey.
Hardness dependent guidelines are calculated using the baseline median hardness of 28 mg/L as $CaCO_3$.
Ammonia guidelines assume a pH of 8.0 and temperature of 15°C.
Chromium guideline is for Cr(VI).

Notes:
BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Concentrations that exceed long-term guidelines are shown as underlined font.
Concentrations that exceed short-term guidelines are shown as bold font.
Concentrations that exceed the discharge limit are shaded in grey.
Hardness dependent guidelines are calculated using the baseline median hardness of 28 mg/L as $CaCO_3$.
Ammonia guidelines assume a pH of 8.0 and temperature of 15°C.
Chromium guideline is for Cr(VI).

Notes:
BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Concentrations that exceed long-term guidelines are shown as underlined font.
Concentrations that exceed short-term guidelines are shown as bold font.
Concentrations that exceed the discharge limit are shaded in grey.
Hardness dependent guidelines are calculated using the baseline median hardness of 28 mg/L as $CaCO_3$.
Ammonia guidelines assume a pH of 8.0 and temperature of 15°C.
Chromium guideline is for Cr(VI).

Notes:
BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Concentrations that exceed long-term guidelines are shown as underlined font.
Concentrations that exceed short-term guidelines are shown as bold font.
Concentrations that exceed the discharge limit are shaded in grey.
Hardness dependent guidelines are calculated using the baseline median hardness of 28 mg/L as $CaCO_3$.
Ammonia guidelines assume a pH of 8.0 and temperature of 15°C.
Chromium guideline is for Cr(VI).

Discharge Limit	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	0.00046	-	0.0050	-	-	0.0010	-

Notes:
BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Concentrations that exceed long-term guidelines are shown as underlined font.
Concentrations that exceed short-term guidelines are shown as bold font.
Concentrations that exceed the discharge limit are shaded in grey.
Hardness dependent guidelines are calculated using the baseline median hardness of 28 mg/L as $CaCO_3$.
Ammonia guidelines assume a pH of 8.0 and temperature of 15°C.
Chromium guideline is for Cr(VI).

Notes:
BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Concentrations that exceed long-term guidelines are shown as underlined font.
Concentrations that exceed short-term guidelines are shown as bold font.
Concentrations that exceed the discharge limit are shaded in grey.
Hardness dependent guidelines are calculated using the baseline median hardness of 28 mg/L as $CaCO_3$.
Ammonia guidelines assume a pH of 8.0 and temperature of 15°C.
Chromium guideline is for Cr(VI).

Notes:
BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Concentrations that exceed long-term guidelines are shown as underlined font.
Concentrations that exceed short-term guidelines are shown as bold font.
Concentrations that exceed the discharge limit are shaded in grey.
Hardness dependent guidelines are calculated using the baseline median hardness of 28 mg/L as $CaCO_3$.
Ammonia guidelines assume a pH of 8.0 and temperature of 15°C.
Chromium guideline is for Cr(VI).

Discharge Limit	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	0.00046	-	0.0050	-	-	0.0010	-	-

Notes:
BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Concentrations that exceed long-term guidelines are shown as underlined font.
Concentrations that exceed short-term guidelines are shown as bold font.
Concentrations that exceed the discharge limit are shaded in grey.
Hardness dependent guidelines are calculated using the baseline median hardness of 28 mg/L as $CaCO_3$.
Ammonia guidelines assume a pH of 8.0 and temperature of 15°C.
Chromium guideline is for Cr(VI).

Notes:
BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Concentrations that exceed long-term guidelines are shown as underlined font.
Concentrations that exceed short-term guidelines are shown as bold font.
Concentrations that exceed the discharge limit are shaded in grey.
Hardness dependent guidelines are calculated using the baseline median hardness of 28 mg/L as $CaCO_3$.
Ammonia guidelines assume a pH of 8.0 and temperature of 15°C.
Chromium guideline is for Cr(VI).

APPENDIX 3.2: WATER QUALITY PREDICTIONS AT STATION BJ 2.62

Appendix 3.2-1: Maximum Base Case Predictions for Scenario 1 at BJ 2.62

Notes:
BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Concentrations that exceed long-term guidelines are shown as underlined font.
Concentrations that exceed short-term guidelines are shown as bold font.
Concentrations that exceed the discharge limit are shaded in grey.
Hardness dependent guidelines are calculated using the baseline median hardness of 28 mg/L as $CaCO_3$.
Ammonia guidelines assume a pH of 8.0 and temperature of 15°C.
Chromium guideline is for Cr(VI).

Notes:
BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Concentrations that exceed long-term guidelines are shown as underlined font.
Concentrations that exceed short-term guidelines are shown as bold font.
Concentrations that exceed the discharge limit are shaded in grey.
Hardness dependent guidelines are calculated using the baseline median hardness of 28 mg/L as $CaCO_3$.
Ammonia guidelines assume a pH of 8.0 and temperature of 15°C.
Chromium guideline is for Cr(VI).

Notes:
BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Concentrations that exceed long-term guidelines are shown as underlined font.
Concentrations that exceed short-term guidelines are shown as bold font.
Concentrations that exceed the discharge limit are shaded in grey.
Hardness dependent guidelines are calculated using the baseline median hardness of 28 mg/L as $CaCO_3$.
Ammonia guidelines assume a pH of 8.0 and temperature of 15°C.
Chromium guideline is for Cr(VI).

Notes:
BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Concentrations that exceed long-term guidelines are shown as underlined font.
Concentrations that exceed short-term guidelines are shown as bold font.
Concentrations that exceed the discharge limit are shaded in grey.
Hardness dependent guidelines are calculated using the baseline median hardness of 28 mg/L as $CaCO_3$.
Ammonia guidelines assume a pH of 8.0 and temperature of 15°C.
Chromium guideline is for Cr(VI).

Notes:
BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Concentrations that exceed long-term guidelines are shown as underlined font.
Concentrations that exceed short-term guidelines are shown as bold font.
Concentrations that exceed the discharge limit are shaded in grey.
Hardness dependent guidelines are calculated using the baseline median hardness of 28 mg/L as $CaCO_3$.
Ammonia guidelines assume a pH of 8.0 and temperature of 15°C.
Chromium guideline is for Cr(VI).

Notes:
BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Concentrations that exceed long-term guidelines are shown as underlined font.
Concentrations that exceed short-term guidelines are shown as bold font.
Concentrations that exceed the discharge limit are shaded in grey.
Hardness dependent guidelines are calculated using the baseline median hardness of 28 mg/L as $CaCO_3$.
Ammonia guidelines assume a pH of 8.0 and temperature of 15°C.
Chromium guideline is for Cr(VI).

Notes:
BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Concentrations that exceed long-term guidelines are shown as underlined font.
Concentrations that exceed short-term guidelines are shown as bold font.
Concentrations that exceed the discharge limit are shaded in grey.
Hardness dependent guidelines are calculated using the baseline median hardness of 28 mg/L as $CaCO_3$.
Ammonia guidelines assume a pH of 8.0 and temperature of 15°C.
Chromium guideline is for Cr(VI).

Discharge Limit	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	0.00046	-	0.0050	-	-	0.0010	-	-

Notes:
BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Concentrations that exceed long-term guidelines are shown as underlined font.
Concentrations that exceed short-term guidelines are shown as bold font.
Concentrations that exceed the discharge limit are shaded in grey.
Hardness dependent guidelines are calculated using the baseline median hardness of 28 mg/L as $CaCO_3$.
Ammonia guidelines assume a pH of 8.0 and temperature of 15°C.
Chromium guideline is for Cr(VI).

Notes:
BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Concentrations that exceed long-term guidelines are shown as underlined font.
Concentrations that exceed short-term guidelines are shown as bold font.
Concentrations that exceed the discharge limit are shaded in grey.
Hardness dependent guidelines are calculated using the baseline median hardness of 28 mg/L as $CaCO_3$.
Ammonia guidelines assume a pH of 8.0 and temperature of 15°C.
Chromium guideline is for Cr(VI).

Notes:
BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Concentrations that exceed long-term guidelines are shown as underlined font.
Concentrations that exceed short-term guidelines are shown as bold font.
Concentrations that exceed the discharge limit are shaded in grey.
Hardness dependent guidelines are calculated using the baseline median hardness of 28 mg/L as $CaCO_3$.
Ammonia guidelines assume a pH of 8.0 and temperature of 15°C.
Chromium guideline is for Cr(VI).

Notes:
BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Concentrations that exceed long-term guidelines are shown as underlined font.
Concentrations that exceed short-term guidelines are shown as bold font.
Concentrations that exceed the discharge limit are shaded in grey.
Hardness dependent guidelines are calculated using the baseline median hardness of 28 mg/L as $CaCO_3$.
Ammonia guidelines assume a pH of 8.0 and temperature of 15°C.
Chromium guideline is for Cr(VI).

Notes:
BC FWAL = BC water quality guidelines for protection of freshwater aquatic life.
Concentrations that exceed long-term guidelines are shown as underlined font.
Concentrations that exceed short-term guidelines are shown as bold font.
Concentrations that exceed the discharge limit are shaded in grey.
Hardness dependent guidelines are calculated using the baseline median hardness of 28 mg/L as $CaCO_3$.
Ammonia guidelines assume a pH of 8.0 and temperature of 15°C.
Chromium guideline is for Cr(VI).

Appendix 4: Streamflow Ratios Supporting Dilution Analyses in Brucejack Creek and Sulphurets Creek

PRETIVM

Memorandum

Date: January 18, 2017

To: Robert Goldblatt, Lorax Environmental Services Ltd., and Sylvia Van Zalingen, Environmental Manager, Pretium Resources Inc.

CC: Greg Norton, ERM Partner

From: ERM Consultants Canada Ltd.

Subject: **Streamflow Ratios Supporting Dilution Analyses in Brucejack Creek and Sulphurets Creek**

1. INTRODUCTION

The geographic extent of potential effects from elevated nitrate and nitrite are defined as waters (i.e. receiving environment) with predicted concentrations greater than the British Columbia Water Quality Guidelines (BCWQGs) for the protection of aquatic life. Brucejack Creek at BJ 3.10 is predicted to have concentrations of nitrate and nitrite greater than their respective BCWQGs. Brucejack Creek flows into Sulphurets Creek at SC0, where nitrate and nitrite concentrations are below the BCWQGs (Table 1).

Table 1. Dilution required to equal BC Water Quality Guidelines in Sulphurets Creek

Parameter	Model case	BJ 3.10 (mg-N/L)	SC0 (mg-N/L)	BCWQG (mg-N/L)	Required Dilution
Nitrate	Expected Case	5.1	0.05	3.0	1:1
	Upper Case	11.5	0.05	3.0	3:1
Nitrite	Expected Case	0.11	0.001	0.02	5:1
	Upper Case	0.24	0.001	0.02	12:1

The maximum required dilution is 12:1 Brucejack Creek at BJ 3.10 to Sulphurets Creek at SC0 (to produce NO_2 <0.02 mg-N/L). This memorandum provides an update to the assessment of streamflow ratios along Sulphurets Creek, and includes the results of previous studies, as well as a description of the methodology used to assess ratios used in this update.

2. BACKGROUND

ERM (2014) provided streamflow ratio estimates that support a dilution analysis of flows from Brucejack Creek into Sulphurets Creek. Three approaches were used to estimate streamflow ratio:

a) *use of drainage area as a surrogate for streamflow ratio;*

b) *analysis of data collected during the baseline monitoring program (open water season only); and*

c) *regional hydrologic analysis.*

The ratio of streamflow at Sulphurets Lake Outflow (at hydrometric station SL-H1) to streamflow at Brucejack Creek (at hydrometric station BJ 1.74, also known as BJL-H1a), using *Methods a*, *b*, and *c*, were 8.8, 14.6, and 9.7, respectively (ERM 2014). Based on these results, ERM (2014) concluded that the drainage area approach (i.e., *Method a*) provides the most conservative estimates for streamflow ratios, with 8:1 being the ratio selected for the Sulphurets Lake Inflow compared to Brucejack Creek at BJ 1.74. This conclusion assumes that drainage area ratios (*Method a*) may be used as a surrogate for streamflow ratios, which may further be used as a surrogate for dilution ratios.

ERM (2016) was completed and superseded ERM (2014) following collection of additional 366 concurrent daily streamflow records (June to September 2013-2015). It was found that additional data did not change ERM (2014) recommendations (ERM 2016). Catchment area ratios consistently provided the most conservative streamflow ratio and so was recommended.

Streamflow ratios, determined from the ratio of measured discharge, is the preferred method (*Method b*), but these results were not chosen in the previous study (*Method a*) due to the limited extent of site record available, and use of open water season data only.

3. 2017 STREAMFLOW RATIOS

ERM has recently completed a detailed hydrologic analysis of the major tributaries of the Sulphurets Valley, which resulted in the development of a series of long-term transposed streamflow records for select hydrometric monitoring stations (Table 2). These records (each 66 years in length) were derived by integrating project hydrometric records, with long-term regional Water Survey of Canada records, using the empirical frequency pairing method described in Butt (2013).

The monthly distribution of average streamflow in Brucejack Creek is different from Sulphurets Creek (Plate 1), and these differences impact streamflow ratios at different times of the year. The highest monthly flows in Brucejack Creek occur during the prominent freshet peak, while for Sulphurets Creek, the highest flows occur during the summer months, in response to melting of large, lower elevation glaciers. Thus, major differences in runoff between Brucejack Creek and Sulphurets Creek result from the presence, size, orientation and elevation of glaciers, and that the catchment area ratio (*Method a*) did not reflect these differences accurately.

Plate 1. Monthly Distribution of Streamflow

The long-term transposed streamflow records were used to more accurately determine the ratios of streamflow at Brucejack Creek (at BJ 3.10), to various nodes along Sulphurets Creek using average monthly flows (Table 3). The process was straight forward, though some nodes were not located at specific monitoring stations, and thus minor spatial extrapolation of runoff was necessary. Extrapolation was achieved by assuming that flows downstream of monitoring stations were a function of non-glaciated runoff conditions, which was calculated for each node as proportional runoff, based on a mass balance of flows in the Sulphurets Valley.

Table 2. Hydrometric Stations with Long-Term Transposed Streamflow Records

#	Node	Description	Easting	Northing	Catchment (km^2)
1	BJ 1.74	Brucejack Creek, 1.74 km upstream of Confluence	425737	6259076	8.5
2	SL-H2	Sulphurets Creek, downstream of Sulphurets Lake	419769	6261350	75.6
3	TMC-H1	Ted Morris Creek	416883	6259497	56.6
4	MC-H2	Mitchell Creek, immediately upstream of Confluence	416740	6262837	87.9
5	GC-H1	Gingras Creek, immediately upstream of Confluence	416277	6262834	9.8
6	SC-H1	Sulphurets Creek, at the Mouth	408256	6261490	289.4

Table 3. Sulphurets Valley Dilution Ratio Node Details

Node	Alias	Easting	Northing	Catchment (km^2)	Catchment Ratio[1]
Brucejack Lk (BJ 3.10)	BJ 3.10	427030	6258895	6.7	1
Sulphurets Creek d/s Sulphurets Lk	SL-H2	419769	6261350	75.6	11
Sulphurets Creek, u/s Ted Morris Crk	SC-TMU	417520	6261990	86.8	13
Sulphurets Creek, d/s Ted Morris Crk	SC-TMD	417285	6262111	149.8	22
Sulphurets Creek, u/s Mitchell Crk	SC-MCU	416354	6262487	151.5	23

Notes:

1. *Catchment Ratio provided as a reference, using the methodology described in ERM (2014), Method "a"*

Previous studies were based on discharge data from BJ 1.74. Therefore, streamflow for BJ 1.74 was transposed to BJ 3.10 by catchment area proration. Long-term streamflow were then determined at other nodes by using the long-term streamflow records from nearby monitoring stations, and integrating where necessary to provide reasonable estimates of discharge at the specific node.

- SL-H2 used the long-term transposed records of the monitoring station SL-H2,
- SC-TMU used SL-H2, with the addition of runoff from the non-glaciated catchment area downstream of the monitoring station SL-H2,
- SC-TMD used SC-TMU, with the addition of runoff from the monitoring station TMC-H1, and the addition of runoff from the non-glaciated Ted Morris Valley catchment downstream of TMC-H1,
- SC-MCU used SC-TMD, with the addition of runoff from the non-glaciated catchment Sulphurets Valley catchment area downstream of SC-TMD.

Monthly streamflow is included in Table 4, and monthly ratios are included in Table 5 and Plate 2 (the dashed line represents the 12:1 discharge ratio).

Table 4. Average Monthly Streamflow (m^3/s) at nodes along Sulphurets Valley

Node	JAN	FEB	MAR	APR	MAY	JUN	JUL	AUG	SEP	OCT	NOV	DEC

Plate 1. Streamflow Ratios at Nodes Along Sulphurets Valley

4. CLOSING

ERM used long-term streamflow estimates to derive estimates of streamflow ratios at nodes along the Sulphurets Valley. It was found that the required 12:1 streamflow ratio (compared to streamflow in Brucejack Creek at BJ 3.10) will be comfortably achieved in all months, immediately below the Ted Morris confluence, at SC-TMD.

Should you have any questions or concerns, please do not hesitate to contact ERM.

Appendix 5: Review of As and Sb Aquatic Toxicity Literature

PRETIVM

MEMORANDUM

To:	**Sylvia Van Zalingen and Max Holtby (Pretivm)**	**Date:18 December 2017**
From:	**Meghan Goertzen and Robert Goldblatt (Lorax)**	**Project: A406-1**
Subject:	**Antimony and arsenic toxicity literature review and site-specific toxicity test**	

1. Introduction

This memorandum presents an antimony and arsenic toxicity literature review and results of a site-specific toxicity test completed in support of Pretium Resources Inc.'s (Pretivm's) application to amend Brucejack Gold Mine Effluent Permit 107835 to (1) include a discharge limit for antimony (Sb) of 28 µg/L and (2) increase the arsenic (As) discharge limit from 5 µg/L to 10 µg/L. The memorandum provides a review of literature-based Sb and As toxicity data sets, and presents results of a toxicity using site water and added As and Sb. The memorandum provides an assessment of the proposed discharge limits in relation to these toxicity data.

Section 2 provides a summary of aquatic toxicity literature that was used to derive the BC freshwater aquatic life (FWAL) guidelines for Sb and As. Also included are the results from a search of toxicity studies published after the BC FWAL guidelines were published, to assess whether more recent data would change the derivation of the guideline. The summary of all published toxicity data is used to assess the potential for toxicity resulting from the proposed discharge limits.

Section 3 presents the results of a toxicity test performed on effluent from Brucejack Gold Mine amended with various concentrations of As and Sb. The test was designed to determine toxicity endpoints of these elements in site water, using a species that is known to be particularly sensitive to arsenic. The results of the toxicity test provide a second line of evidence for the assessment of potential toxic effects from the proposed discharge limits. The memorandum concludes with a summary (Section 4).

2. Literature Review of Toxicity Data

2.1 Antimony

The BC working freshwater aquatic life (FWAL) guideline for antimony is 9 µg/L for Sb(III). The guideline specifies the trivalent form of antimony because the majority of toxicological studies were done using Sb(III). The other form of antimony that may occur in natural water is Sb(V), which predominates in highly oxidizing environments (ANZECC, 2000). Routine water quality monitoring for Brucejack Gold Mine measures total Sb, rather than individual Sb species such as Sb(III) or Sb(V); therefore, it is necessary to compare T-Sb measurements to the BC FWAL guideline for Sb(III).

The BC FWAL guideline was adopted from the Australia and New Zealand water quality guidelines (ANZECC, 2000), which states:

> *A freshwater low reliability trigger value of 9 µg/L was derived for antimony (III) from the fish figure using an AF of 1000. This figure should only be used as an indicative interim working level. Collection of more data would assist in revision of this figure.*

ANZECC classified the trigger as "low reliability" due to the paucity of acceptable Sb toxicity data, particularly chronic toxicity tests. The trigger was derived from the lowest acceptable toxicity test endpoint, a 96-h LC50 of 9000 µg/L for *Pimephales promelas* (fathead minnow), and an uncertainty factor of 0.001. This is an unusually conservative degree of safety for deriving long-term guidelines from an acute toxicity endpoint, which is why the ANZECC guideline classifies it as a low reliability trigger.

Antimony toxicity literature has been reviewed for the development of an Interim Provincial Water Quality Objective by Ontario (Fletcher *et al.*, 1996) and for a review of the acute ecotoxicity data for Sb for the Environmental Hazard Identification in the U.S. (PricewaterhouseCoopers, 2001). Both reviews found that many of the published studies with high toxicity endpoints were not reliable because the actual concentration of Sb in the test solutions was not measured. Most studies used antimony trioxide (Sb_2O_3) or antimony trichloride ($SbCl_3$) to make stock solutions, both of which are not readily soluble in water. For these studies, the nominal concentrations used to calculate toxicity statistics likely overestimated the actual concentration that organisms were exposed to.

Fletcher classified nine acute toxicity endpoints as primary (having acceptable data) and five chronic toxicity endpoints as primary (Table 2-1). PricewaterhouseCoopers (2001) classified 3 of the 16 acute endpoints that they reviewed as reliable (Table 2-1). The lowest reliable endpoint is 300 µg/L for survival of eggs of the narrow-mouthed toad in a 7-day exposure (Birge, 1978). In the same publication by Birge (1978), a 28-day rainbow trout egg survival endpoint of 560 µg/L is reported, but Fletcher *et al*. (1996) classify this endpoint as secondary (*i.e.*, less reliable than primary data).

No Sb toxicity endpoints have been reported in literature after 2001 that are more sensitive than those described above. The U.S. ECOTOX database reports two Sb toxicity endpoints published after 2000 (Borgmann et al., 2005; Khangarot & Das, 2009), both of which report Sb toxicity endpoints at >1,300 µg/L. A search of the primary literature for recent studies not in the ECOTOX database revealed one other study by Nam *et al.* (2009) which reported an effect on growth of a green alga at 206,000 µg/L.

Table 2-1:
Antimony Toxicity Studies

Scientific Name	Common Name	Test Duration	Effect	Endpoint[3]	Concentration (ug/L)	Source	Reliability
Acute							
Gastrophryne carolinensis	Eastern narrow-mouthed toad	7 d	Mortality	LC_{50}	300	Birge (1978)	Primary[1]
Hydra oligactis	Brown hydra	96 h	Immobility	EC_{50}	500	Brooke *et al*. (1986)

Chlorella vulgaris	Alga	4 -mo	Growth	Adverse effect	7,800	den Dooren de Jong (1965)	
Pimephales promelas	Fathead minnow	30 d	Mortality	LOEC	9,300	Kimball (1978)	Primary[1]
Oncorhynchus mykiss	Rainbow trout	30 d	Mortality	LC_{50}	16,000	Doe *et al*. (1987)	Primary[1]
Lemna minor	Duckweed	96 h	Growth	EC_{50}	25,500	Brooke *et al*. (1986)	
Pseudokirchneriella subcapitata	Alga	72 h	Growth	EC_{50}	206,000	Nam *et al*. (2009)	

1. Fletcher *et al*. 1996 classify this endpoint as primary data.
2. PricewaterhouseCoopers classify this endpoint as reliable.
3. Endpoints are median lethal (LC50) or median effect (EC50) concentration, or Lowest Observed Effect Concentration.
   Rows shown as blue font are studies that have been classified as secondary or not reliable.

The lowest reliable Sb toxicity endpoint in the literature that is directly relevant to the aquatic community in Brucejack Creek is the 30-day *Daphnia magna* median lethal endpoint (LC50) of 1,700 µg/L (Doe *et al.*, 1987). This is considered a chronic endpoint because the average lifespan of *D. magna* is about 40 days at 25 °C. The green alga endpoint of 740 µg/L (USEPA, 1978) is also relevant to aquatic life in Brucejack Creek, but the validity of the data from this study is uncertain (PricewaterhouseCoopers, 2001). The data on Sb toxicity in the literature provide a high confidence that the proposed effluent discharge limit of 28 µg/L will not produce toxic effects to the aquatic community in the receiving environment.

2.2 Arsenic

The BC FWAL guideline for total arsenic is 5 µg/L. This value was adopted from the CCME (2001) guideline which applied an uncertainty factor of 0.1 to the lowest endpoint in the literature of 50 µg/L [a EC_{50} for growth of the green alga *Scenedesmus obliquus* (Vocke *et al.*, 1980)]. CCME also reported that two other algal species were the next most sensitive species to arsenic toxicity, and that invertebrates and fish were less sensitive than algae.

The BC arsenic guideline Overview Report (BCMOE, 2002) states that the CCME guideline of 5 µg/L was judged to be sufficiently protective of water uses in the province of B.C., and this guideline was adopted without change. The Overview Report notes that there is one arsenic study that reports a toxicity endpoint that is lower than the 50 µg/L EC50 *S. obliquus* endpoint used to derive the guideline. A *D. magna* 21-day growth study yielded a Lowest Observed Effect Concentration of 38 µg/L for arsenic acid (US EPA, 1992). This study was reviewed by the European Chemicals Agency and classified as “not reliable” (ECHA, 2011). The ECHA is an agency of the European Union that manages the technical, scientific, and administrative aspects of implementation of the EU’s Registration, Evaluation, Authorisation and Restriction of Chemicals.

A compilation of other *D. magna* chronic endpoints indicates that the 38 µg/L endpoint cited by BCMOE (2002) is anomalously lower than other chronic endpoints for the same species, even from the same USEPA (1992) study (Table 2-2). There are only 3 other publications in the ECOTOX database that report chronic toxicity of arsenic to any daphnid species (all are *D. magna*) and these provide supporting evidence to support the ECHA conclusion that the USEPA (1992) endpoint is not reliable.

Table 2-2:
***Daphnia magna* Chronic Toxicity Endpoints**

Duration	Endpoint	Effect	Concentration (µg/L)	Reference
21 d	LOEC	Growth	38	USEPA (1992)
21 d	LOEC	Growth	880	USEPA (1992)
21 d	LOEC	Reproduction	880	USEPA (1992)
21 d	EC_{50}	Reproduction	1,400	Biesinger and Christensen (1972)
21 d	IC_{25}	Reproduction	1,900	Tisler and Zagorc-Koncan (2002)
21 d	LC_{50}	Mortality	2,850	Biesinger and Christensen (1972)
21 d	LOEC	Growth	3,400	Enserink *et al*. (1991)
21 d	LOEC	Reproduction	3,700	Tisler and Zagorc-Koncan (2002)
21 d	LC_{50}	Mortality	5,800	Enserink *et al.* (1991)

The ECOTOX database includes 26 references that were published after the CCME (2001) arsenic guideline; these studies report arsenic toxicity endpoints for 24 different species which range from. 172 µg/L to >10,000 µg/L. Thus, the basis for the BC FWAL guideline of an EC_{50} of 50 µg/L for a green alga species would not change based on more recent studies. This updated toxicity dataset provides a high level of confidence that the proposed arsenic discharge limit of 10 µg/L will not produce toxic effects to the aquatic community in the receiving environment.

3. Site Specific Toxicity Test

Pretivm commissioned a toxicity test using water collected from the Brucejack Lake outlet (site BJ 3.10) with various concentrations of arsenic and antimony added (Appendix 6 of Lorax, 2017). The test was conducted using the green algal species *Pseudokirchneriella subcapitata* (formerly called *Selenastrum capricornutum*) since the literature shows that green algae are sensitive to arsenic toxicity. Both As and Sb were added to the test solutions because these two metals were observed to be gradually increasing in Brucejack Lake following start of mine construction. Arsenic and antimony were added at a ratio of 1:1.25, by atomic weight, which is the same ratio that has been consistently measured at BJ 3.10 in 2017. This is a molar ratio of 1:0.77 As:Sb.

BJ 3.10 water was collected on October 30, 2017 and arrived at Nautilus Environmental Company Inc. in Burnaby B.C. on November 1, 2017. The test was conducted according to the procedure described by Environment Canada (2007). The test measured the growth of algae in site water with added As and Sb and compared the site water results to growth in laboratory

control water. The concentrations of As and Sb in each test solution were analyzed by ALS Environmental, and statistics were calculated using the measured concentrations. The test conducted met all quality assurance requirements.

The results listed in Table 3-1 are the combined effects of As and Sb added to each test solution. The literature review of toxicity of antimony and arsenic shows that arsenic is more toxic than antimony. The lowest As toxicity endpoint in the literature is 50 µg/L and the lowest Sb toxicity endpoint is 300 µg/L. Therefore, it is almost certain that the toxicity observed in the BJ 3.10 test was due to As, and the calculated Sb endpoints should not be interpreted as a concentration where toxicity due to Sb is expected. A test without any additions other than Sb would be required to determine Sb toxicity endpoints.

The median effect concentration (IC50) in BJ 3.10 water was 74 µg/L T-As (Table 3-1), which is a little higher than the median effect concentration that the BC FWAL guideline is based on (EC50 = 50 µg/L T-As). There was no effect on growth in the BJ 3.10 water control or of the T-As = 11.4 µg/L solution, compared to growth in the laboratory control water. The lowest observed effect concentration was 18.7 µg/L T-As. These test results, on a species that is known to be sensitive to arsenic toxicity, indicate that no adverse effects to aquatic life in Brucejack Creek are expected from the proposed discharge limit of 10 µg/L.

Table 3-1:
***Pseudokrchneriella subcapitata* Growth Inhibition Test Results**

Treatment	T-As (ug/L)	T-Sb (ug/L)	Cell Yield ($\times 10^4$cells/ml) (Mean ± 1 SD)
Laboratory control	0	0	27.6 ± 2.4
Un-amended BJ 3.10	4.55	6.17	152.8 ± 10.2
Concentration 1	11.4	14.1	152.5 ± 9.1
Concentration 2	18.7	23.2	132.8 ± 4.8
Concentration 3	31.6	39.4	132.8 ± 8.2
Concentration 4	60.4	78.6	93.5 ± 6.5
Concentration 5	115	144	39.2 ± 4.2
Concentration 6	224	289	19 ± 2.2
Concentration 7	461	573	4 ± 0.8
Test Endpoints			
IC50 (95% CL)	74.1 (67.5–81.7)	95.2 (85.6–101.5)	
LOEC	18.7	23.2	
NOEC	11.4	14.1	

4. Summary

The results of this memorandum are summarized as follows:

- The lowest antimony toxicity endpoint in the literature is 300 µg/L, for toxicity to frog embryo.
- The lowest antimony toxicity endpoint in the literature for species that may be representative of the Brucejack Creek aquatic community is 1,700 µg/L for toxicity to *Daphnia magna*.
- The lowest arsenic toxicity endpoint in the literature is 50 µg/L, for green algae, which is representative of periphyton present in Brucejack Creek.
- The lowest observed effect concentration (LOEC) for arsenic from a toxicity test using a green alga species and BJ 3.10 water is 18.7 µg/L.
- Literature-based toxicity tests and the site-specific toxicity test results support the conclusion that the proposed effluent discharge limits of 28 µg/L T-Sb and 10 µg/L T-As will not cause significant adverse effects to aquatic life in Brucejack Creek.

5. Closure

We trust that this memorandum meets your requirements.

Report By: Mimi Tran, Dipl. T. Laboratory Biologist	Reviewed By: Edmund Canaria, R.P.Bio Environmental Biologist- Senior Analyst

This report has been prepared by Nautilus Environmental Company Inc. based on data and/or samples provided by our client and the results of this study are for their sole benefit. Any reliance on the data by a third party is at the sole and exclusive risk of that party. The results presented here relate only to the samples tested.

SUMMARY

Sample Information and Test Type

Sample IDs and Treatment	Weir at 3.10 and laboratory water amended with arsenic (As) and antimony (Sb)
Collection date	October 30, 2017 (Weir at 3.10)
Receipt date	November 1, 2017 (Weir at 3.10)
Sample test treatment preparation/amendment date	November 1, 2017 for Weir at 3.10 and laboratory water
Receipt temperature	8.8°C (Weir at 3.10)
Test types	72-h *Pseudokirchneriella subcapitata* growth inhibition

Summary of Results (amended laboratory water test)

Endpoint	µg/L As	µg/L Sb
P. subcapitata		
Growth IC25 (95% CL)	10.9 (3.8 – 90.6)	17.0 (9.3 – 121.9)
Growth IC50 (95% CL)	122.6 (92.8 – 143.6)	162.6 (121.2 – 193.4)
NOEC	3.5	8.5
LOEC	7.1	12.8

IC = Inhibition Concentration, NOEC = No Observed Effect Concentration, LOEC = Lowest Observed Effect Concentration, CL = Confidence Limits

Summary of Results (amended Weir at 3.10 test)

Endpoint	µg/L As	µg/L Sb
P. subcapitata		
Growth IC25 (95% CL)	42.7 (33.3 – 48.0)	54.3 (42.6 – 60.7)
Growth IC50 (95% CL)	74.1 (67.5 – 81.7)	95.2 (85.6 – 101.5)
NOEC	11.4	14.1
LOEC	18.7	23.2

IC = Inhibition Concentration, NOEC = No Observed Effect Concentration, LOEC = Lowest Observed Effect Concentration, CL = Confidence Limits

1.0 INTRODUCTION

Nautilus Environmental Company Inc. conducted 72-h *Pseudokirchneriella subcapitata* growth inhibition tests for Pretium Exploration. Sample Weir at 3.10 was collected on October 30, 2017 and delivered to the Nautilus Environmental laboratory in Burnaby, BC on November 1, 2017. The sample was transported in one 20-L plastic container and was received at a temperature of 8.8°C. The sample was stored in the dark at 4 ± 2°C prior to testing.

Sample Weir at 3.10 was amended with a range of arsenic (As) and antimony (Sb) concentrations, according to instructions provided by Lorax Environmental prior to testing. A concurrent test, using *P. subcapitata* laboratory control water, amended to the same arsenic and antimony concentrations as the sample, was also performed. Testing was initiated on November 1, 2017.

This report describes the results of the toxicity tests. Copies of raw laboratory data sheets and statistical analyses are provided in Appendix A. Copies of analytical chemistry analyses supplied by Lorax Environmental are provided in Appendix B. The chain-of-custody form is provided in Appendix C.

2.0 METHODS

Methods for the toxicity tests are summarized in Table 1. Testing using *P. subcapitata* was conducted according to procedure described by Environment Canada (2007).

The amended Weir at 3.10 and laboratory water test solutions were prepared at the Nautilus Environmental laboratory using an in-house concentrated arsenic stock solution, and a concentrated antimony stock solution supplied by Lorax Environmental. Aliquots of each prepared test solution were sent to ALS Environmental, Burnaby, BC for measurement of total and dissolved arsenic and antimony. Analytical results were reported directly to Lorax Environmental, and subsequently supplied to Nautilus Environmental for inclusion in the final report. Table 1 provides a summary of the nominal and total measured arsenic and antimony concentrations.

Statistical analyses for the tests were performed using CETIS (Tidepool Scientific Software, 2013). The test endpoints were calculated using total measured arsenic and antimony values, as instructed by Lorax Environmental.

Table 1. Nominal and total measured As and Sb concentrations in laboratory water and sample Weir at 3.10.

Test Treatment	µg/L As		µg/L Sb	
	Nominal	Total Measured	Nominal	Total Measured
Laboratory Water				
Laboratory Control	0	0	0	0
Concentration 1	3.5	3.5	4.4	8.47
Concentration 2	7	7.09	8.8	12.8
Concentration 3	14	13.9	18	20
Concentration 4	28	28.4	35	37.3
Concentration 5	56	56.2	70	76.6
Concentration 6	112	110	141	146
Concentration 7	224	220	282	291
Concentration 8	448	441	563	593
Weir at 3.10				
Laboratory Control	0	0	0	0
Un-amended Weir at 3.10	3.33	4.55	4.55	6.17
Concentration 1	7	11.4	8.8	14.1
Concentration 2	14	18.7	18	23.2
Concentration 3	28	31.6	35	39.4
Concentration 4	56	60.4	70	78.6
Concentration 5	112	115	141	144
Concentration 6	224	224	282	289
Concentration 7	448	461	563	573

Table 2. Summary of test conditions: 72-h *Pseudokirchneriella subcapitata* growth inhibition test.

Test species	*Pseudokirchneriella subcapitata*, strain UTCC# 37
Organism source	In-house axenic culture, obtained from Canadian Phycological Culture Center, and originally isolated from Nivelta River, Norway.
Organism age	3-to 7-day old culture in logarithmic growth phase
Test type	Static
Test duration	72 hours
Test vessel	Microplate
Test volume	220 µL
Test concentrations	Full strength sample diluted to 95.2% (v/v) with nutrients (site control), full strength sample diluted to 95.2% (v/v) with nutrients and amended with a range of seven As and Sb concentrations, plus laboratory control. Laboratory control/dilution water amended with a range of eight As and Sb concentrations, plus laboratory control.
Test replicates	4 per treatment; 8 for laboratory control and site control
Number of organisms	10,000 cells/mL
Laboratory control water	Deionized water supplemented with nutrients
Site control dilution water	Full strength sample (Weir at 3.10) diluted to 95.2% (v/v) with nutrients
Test solution renewal	None
Test temperature	24 ± 2°C
Feeding	None
Light intensity	3600 to 4400 lux
Photoperiod	24 hours light
Aeration	None
Test measurements	Test area temperature measured daily; temperature and pH measured at test initiation; pH of two control wells measured at test termination
Test protocol	Environment Canada (2007b), EPS 1/RM/25
Statistical software	CETIS Version 1.8.7
Test endpoint	Algal cell growth inhibition
Test acceptability criteria for controls	>16-fold increase in number of algal cells; CV ≤ 20%; no trend when analyzed using Mann-Kendall test
Reference toxicant	Zinc (added as $ZnCl_2$)

3.0 RESULTS

Results of the toxicity test with *P. subcapitata* are summarized in Table 3. An inhibitory effect on cell yield was observed in the laboratory water spiked with both As and Sb. Analyzing the test data for individual measured total metal, the IC25 and IC50 for arsenic were 10.9 and 122.6 µg/L As, respectively; and with respect to antimony, the IC25 value was 17.0 µg/L Sb and the IC50 value was 162.6 µg/L Sb. The arsenic NOEC for cell yield was 3.5 µg/L As and the LOEC was 7.1 µg/L As. The NOEC and LOEC values for antimony were 8.5 and 12.8 µg/L Sb, respectively.

Results of the toxicity test with *P. subcapitata* on the arsenic and antimony amended Weir at 3.19 sample are summarized in Table 4. Adverse effects on cell yield were also observed in the sample spiked with As and Sb. Note that these results were based on the combined effects of As and Sb. If analyzed for each measured total metal, the resulting IC25 and IC50 values for arsenic were 42.7 and 74.1 µg/L As, respectively; and the IC25 and IC50 values for antimony were 54.3 and 95.2 µg/L, respectively. The NOEC for arsenic was 11.4 µg/L As and the LOEC was 18.7 µg/L As. With respect to antimony, the NOEC was 14.1 µg/L Sb and the LOEC was 23.2 µg/L Sb.

Table 3. Results: 72-h *Pseudokirchneriella subcapitata* growth inhibition test (laboratory control water amended with As and Sb).

Test Treatment	Total Measured As (µg/L)	Total Measured Sb (µg/L)	Cell Yield ($x10^4$ cells/mL) (Mean ±SD)
Laboratory Control	0	0	27.6 ± 1.7
Concentration 1	3.5	8.47	27.2 ± 2.2

LOEC	18.7	23.2	--

SD = Standard Deviation, IC = Inhibition Concentration, NOEC = No Observed Effect Concentration, LOEC = Lowest Observed Effect Concentration, CL = Confidence Limits

4.0 QA/QC

The health history of the test organism used in the exposures was acceptable and met the requirements of the test protocol. The tests met all control acceptability criteria and water quality parameters remained within ranges specified in the protocols throughout the tests. Uncertainty associated with the tests is best described by the standard deviation around the mean and/or the confidence intervals around the point estimates.

Results of the reference toxicant test conducted during the testing program are summarized in Table 7. Results for this test fell within the acceptable range for organism performance of mean and two standard deviation range, based on historical results obtained by the laboratory with these tests. Thus, the sensitivity of the organism used in these tests were appropriate. The reference toxicant test was performed under the same conditions as those used for the samples.

Table 5. Reference toxicant test results.

Test Species	Endpoint	Historical Mean (2 SD Range)	CV (%)	Test Date
P. subcapitata	Growth (IC50): 28.6 µg/L Zn	32.8 (26.5 – 40.6)	11	October 25, 2017

SD = Standard Deviation, CV = Coefficient of Variation, IC = Inhibition Concentration

Pseudokirchneriella subcapitata Summary Sheet

Client: Lorax / Pretium Exploration
Start Date: Nov 2/17
Work Order No.: 171295
Set up by: MG.

Sample Information:

Sample ID: Lab control spiked with Sb and As.
Sample Date: Nov 2/17
Date Received: Nov 2/17
Sample Volume: n/a

Test Organism Information:

Culture Date: Oct 27/17
Age of culture (Day 0): 6d

Zinc Reference Toxicant Results:

Reference Toxicant ID: SC162
Stock Solution ID: 17Zn03
Date Initiated: Oct 25/17

72-h IC50 (95% CL): 28.6 (22.8 - 34.9) ug/L Zn

72-h IC50 Reference Toxicant Mean and Range: 32.8 (26.5 - 40.6) ug/L Zn CV (%): 11

Test Results:

ug/L As	Algal Growth
IC25 ~~%(v/v)~~ mg/L (95% CL)	10.9 (3.8 - 90.6)
IC50 ~~%(v/v)~~ ug/L As mg/L (95% CL)	122.6 (92.8 - 143.6)
NOEC	3.5
LOEC	7.1
