Subsequent humidity cell test work was initiated in 2015 to further assess the anticipated Cr(VI) loads released to mine water. The 2015 experiments were carried out on Brucejack tailings generated from metallurgical tests on the 2012-2013 Bulk Sample and cement from a local supplier (Lafarge Canada). The results (presented in Section 5.1) confirm that soluble Cr(VI) is expected to leach from paste backfill; however, the estimated amount of Cr(VI) released to mine water is significantly lower than originally anticipated.

4.2.2 Chromium in the Brucejack Receiving Environment

The water quality model developed for Brucejack Mine generates predictions for T-Cr and D-Cr, based on a site-specific water balance model and geochemical source terms (refer to Sections 7.1.3 and 4.6 of the Permit Application). Water quality predictions are generated for two key receiving environment locations: BJ 3.10, located near the outlet of Brucejack WRTSF; and BJ 2.62, located in

Brucejack Creek, approximately 700 m downstream of the WRTSF outlet. Effluent is currently regulated at BJ 3.10 under PE- 107835. The water quality predictions were most recently updated for Pretium's 3800 tpd Amendment Application for Permits M-243 and PE-107835 (approved on December 14th, 2018).

Updated Base Case and Upper Case T-Cr predictions at BJ 3.10 are presented in Figure 4-1, as compared to the BC FWAL guideline for hexavalent Cr. Base Case is considered to represent the expected case while Upper Case incorporates conservative geochemical source terms. The updated predictions incorporate revisions to the site water balance and the results of 2015 kinetic test data (Section 5.1) with appropriate scaling factors accounting for temperature, grain size and contact water applied. No mitigation has been applied to the predictions presented.

Based on these results, Cr concentrations are expected to remain below the hexavalent Cr guideline of 1 µg/L throughout mine life (maximum Base Case T-Cr = 0.6 µg/L). However, if an Upper Case scenario was realized, then mitigation measures could be implemented to reduce Cr(VI) concentrations if it became necessary. Cr concentrations are expected to decrease rapidly during the Closure phase once paste backfill placement has ceased. The potential mitigation options and the results of follow-up test work are summarized in the sections below.

Figure 4-1: Upper Case and Base Case dissolved Cr concentration predictions at BJ 3.10 (Brucejack WRTSF outlet) through Operations, Closure and Post-Closure mine phases for mine plan Scenarios 1 and 2 (Scenario 1 assumes that all waste rock is placed in Brucejack WRTSF; Scenario 2 assumes that ~40% is placed in Brucejack WRTSF with the remainder placed as backfill in the underground mine). Results are compared to the BC FWAL maximum guideline for Cr(VI) (1 µg/L).

4.3 MITIGATION OPTIONS

Controlling potential contaminants at the source is best practice. Mitigation of Cr(VI) can be achieved through refinement of source control measures or through various treatment options. Source control measures could include minimizing the amount of paste or shotcrete that comes into contact with mine water; whereas treatment options would involve the addition of a reducing agent (e.g., ferrous sulphate) to convert any soluble Cr(VI) to Cr(III) (Qin et. al, 2005; Hills and Johansen, 2007; Kronos ecochem, 2011; Chang, 2001). Four potential treatment options have been identified for Brucejack Mine:

(i) A reducing agent (such as ferrous sulphate) can be added in the cement manufacturing process;

(ii) A reducing agent can be added in the process of making cemented paste backfill;

(iii) A reducing agent can be added to mine water underground; or

(iv) Alternatively, a treatment train can be added to the WTP to reduce Cr(VI) to Cr(III).

Experience from other jurisdictions indicates that the addition of a reducing agent such as ferrous sulphate is an effective method for reducing Cr(VI) to Cr(III), such that the Cr(VI) concentration is reduced by more than an order of magnitude, which will be protective of the receiving environment.

Based on conversations with cement suppliers, it is not currently feasible to purchase a ferrous sulphate-amended cement product that could be used for cemented paste backfill production (option (i) identified above); however, a ferrous sulphate-amended shotcrete product is available. Experimental test programs were therefore developed to assess the amended shotcrete product, and the efficacy of ferrous sulphate addition to both the tailings-cement mixture (mitigation option (ii)) and mine water directly (option (iii)). In the event that these mitigation options were not effective, option (iv) would be considered.

5 EXPERIMENTAL TEST PROGRAMS

The sections below describe the experimental programs developed to evaluate the efficacy of the mitigation strategies identified in Section 4.3: the addition of ferrous sulphate to cemented paste backfill to prevent leaching of soluble Cr(VI), and the addition of ferrous sulphate to mine water should elevated Cr(VI) concentrations be encountered. The results of test work carried out on ferrous sulphate-amended shotcrete are also summarized in the final section.

5.1 TAILINGS AND PASTE BACKFILL CEMENT TESTS

As per conditions outlined in prior versions of *Mines Act* Permit M-243, Pretium developed a geochemical program to evaluate the leaching potential of hexavalent Cr from cemented paste backfill, which included the initiation of a series of humidity cell test experiments. These experiments were initiated in 2015 and used tailings materials generated from metallurgical test work carried out on ore extracted during the 2012-2013 Bulk Sample Program and cement from Lafarge Canada (in representative proportions). These materials were well characterized in terms of their total Cr and hexavalent contents.

The main goals of the 2015 experiments were:

1. To confirm the 2013 humidity cell test results, along with the associated water quality predictions, using more representative materials (Lafarge cement and tailings generated from more recent metallurgical tests);

2. To determine the speciation of Cr leached from the cemented paste; and

3. To evaluate whether the addition of ferrous sulphate to the paste backfill results in a reduction in the amount of hexavalent Cr leached.

Thickened tailings, derived from metallurgical tests carried out on ore extracted during the 2012-2013 Bulk Sample Program, were used for the development of the 2015 kinetic test program, whereas the tailings used in the 2013 kinetic test program were generated from an earlier series of metallurgical tests. The tailings used in the 2015 program are considered to be more representative of the tailings that will be generated during Operations. Another notable difference between the material used in the initial kinetic programs, is the cement. The 2013 program used Australian General Purpose (GP) cement, whereas the 2015 program used 'Portlandite L10' from Lafarge Canada.

The cement and tailings materials were characterized in terms of Cr speciation and concentrations, the results of which are presented in the following section. A summary of the different humidity cell tests that were initiated is provided in Table 5-1. The program consisted of seven humidity cells, including a tailings control test (T5) composed of tailings as received from the 2012-2013 Bulk Sample Program. The other six humidity cells were comprised of paste tailings with 3.9% cement (by mass), which represents the anticipated typical composition of paste backfill at the Brucejack Mine. T12 (and duplicate T15) represented the unmitigated cemented paste backfill case, whereas the other tests had variable amounts of ferrous sulphate ($FeSO_4 \cdot 7H_2O$) added. Specifically, T13 (and duplicate T16) included an amount of ferrous sulphate representing 0.2% of cement, 2 times the requisite amount based on stoichiometry and the measured Cr content of the cement (67 ppm Cr). T14 (and duplicate T17) included an amount of ferrous sulphate representing 1% of the cement, 10 times the stoichiometrically-determined amount. In this manner, the effect of ferrous sulphate on reducing Cr leaching could be assessed for different dosages.

Table 5-1: Summary of 2015 Tailings Kinetic Tests used to Evaluate Cr Leaching and Mitigation Options

Kinetic Test ID	Test Description	Sample Description			
		Portlandite L10 (Ca(OH)) (% by mass)	Ferrous Sulphate ($FeSO_4 \cdot 7H_2O$)	Particle Size	Dry Wt. (kg)
T5	tailings only	-	-	as received	1
T12	paste with 3.9% cement	3.9%	-	-1/4"	0.8
T13	cemented paste + 0.2% ferrous sulphate	3.9%	0.2% of cement Cr content (2× excess)	-1/4"	0.8
T14	cemented paste + 1% ferrous sulphate	3.9%	1% of cement Cr content (10× excess)	-1/4"	0.8
T15	duplicate of T12				
T16	duplicate of T13				
T17	duplicate of T14				

Ferrous sulphate granules were ground to a powder and mixed with the dry cement prior to mixing the cement with the tailings. Proportions of cement and iron sulphate added to the test samples were derived assuming a tailings solids content of 65% (by mass). The cemented paste samples were

spread on individual silicon baking sheets and cured for 28 days before being crushed to -1/4" and placed in the humidity cells.

The humidity cells were constructed and operated according to the MEND procedure described by Price (2009). Each test consisted of an acrylic cylinder measuring 21 cm in diameter by 10.5 cm in height and fitted with an acrylic perforated disk and nylon mesh. The humidity cells were closed at the surface and fitted with one standard port near the top of the cylinder. The tests were operated at room temperature (20-22°C) and the contents subjected to weekly cycles of three days of humid air followed by three days of dry air before being stirred and flushed with 500 mL of distilled water. The weekly leachates were collected and analysed for pH, conductivity, alkalinity, hardness, sulphate, dissolved metals and dissolved hexavalent Cr.

The full set of static test results for the 2015 thickened tailings samples (T-Tails-1) and the Lafarge cement is presented in Appendix 4.6-1 of the Pretium Brucejack 2015 Mines Act and EMA Permits Annual Report. A summary of the Cr concentrations for the 2015 kinetic test materials and the original 2013 kinetic test materials is presented in Table 5-2. Of particular note, are the lower Cr concentrations of the tailings (11 ppm) and cemented tailings (67 ppm) used in the 2015 program compared to the materials used in the original tests (303 ppm). As previously mentioned, the tailings used in the 2015 program are derived from the 2012-2013 Bulk Sample Program and are considered more representative of the tailings that will be produced during Operations at the Brucejack Mine, while the material used in the 2013 test was from a preliminary metallurgical test. Solid phase element determination of the Lafarge Portlandite L10 cement which will be sourced for the production of cemented paste backfill indicates that the cement comprises 57 to 67 ppm Cr, with 86% indicated to be in the hexavalent form (Table 5-2; Appendix 4.6-1-8 of the 2015 Annual Report).

Table 5-2: Chromium Concentrations in Tailings, Cement and Kinetic Test Sub-samples

Test Description	Kinetic Test ID	T-Cr	Cr(VI)
		ppm	ppm
2015 Tailings Program			
tailings only	T5	11	ND
Lafarge Portlandite L10 cement	NA	67	ND
Lafarge Portlandite L10 cement	NA	57	49
paste with 3.9% cement	T12 (T15)	54	ND
cemented paste + 0.2% ferrous sulphate	T13 (T16)	62	ND
cemented paste + 1% ferrous sulphate	T14 (T17)	78	ND
2013 Tailings Program			
raw paste (tailings only)	T4	303	ND
Australian general purpose (GP) cement	NA	ND	ND
paste with 4% GP cement	HC37	250	ND

Notes: NA = not applicable; ND = no data

The lower Cr concentrations of the 2015 program materials are reflected in the leachate results from the new cemented paste kinetic tests (Figure 5-1). Dissolved Cr concentrations in leachate generated from duplicate crushed samples (T12 and T15) are significantly lower than the original humidity cell

test (HC37), which was assessed using the same analytical approach. The initial flush of Cr in the 2015 testwork is lower by a factor of nearly two and decreases by two orders of magnitude over the tested time period. Chromium speciation analysis of the leachate indicates that essentially all of the Cr is present in the hexavalent form (Figure 5-2).

Evaluation of the cemented paste backfill tests dosed with ferrous sulphate indicates that the addition of ferrous sulphate at the higher dose (an amount representing 1% of the cement by mass or an estimated Fe(II) to Cr(VI) ratio of 30) resulted in a reduction of hexavalent Cr by two orders of magnitude during the initial weeks of kinetic testwork (Figure 5-2). The reduction in Cr(VI) is consistent with the low initial pH of these columns (~3 to 4) (lower plot in Figure 5-2). The influence of pH on the oxidation and reduction reactions of Cr is a complex process; however, in general, high pH values enhance the oxidative power (and solubility of Cr(VI)) while low pH values enhance reduction reactions (and the solubility of Cr(III)) (Dhal et al., 2013). As such, under acidic conditions, Cr exists in the trivalent state as soluble $Cr(OH)^{2+}$ (Erdem et al., 2011). This explains why the T-Cr concentrations are similar between all paste backfill tests, with the only significant differences being the relative abundances of Cr(III) and Cr(VI). As discussed, trivalent Cr is not a concern as it will be treated by the WTP.

The kinetic tests composed of cemented paste backfill with a lower dose of ferrous sulphate (i.e., 0.2% of the cement by mass or an estimated Fe(II) to Cr(VI) ratio of 6) did not show Cr(VI) reduction, indicating that insufficient reductant was added (Figure 5-2). Should this mitigation option be implemented, it will be critical to ensure that sufficient ferrous sulphate is added to the cemented paste backfill mixture.

Figure 5-1: Dissolved Cr concentrations in leachate from cemented paste of the 2015 kinetic test program compared to Cr concentrations in leachate from cemented paste of the 2013 tailings kinetic program (HC37).

Figure 5-2: Kinetic test time series showing changes in dissolved Cr, hexavalent Cr and leachate pH for tailings, paste and ferrous sulphate-amended paste samples from the 2015 tailings program humidity cells.

5.2 UNDERGROUND MINE WATER

A series of experiments were developed to assess whether direct treatment of mine water with ferrous sulphate ($FeSO_4$) is an effective mitigation option for hexavalent Cr in underground mine water. This mitigation could be implemented as necessary to individual areas within the underground mine where elevated Cr concentrations are encountered (e.g., individual sumps). The experimental approach and the full set of results are described in a separate report (Lorax, 2019). A summary of the results relevant to Cr management are presented below.

The experiments were carried out using underground mine water spiked with variable amounts of hexavalent Cr, yielding Cr(VI) concentrations ranging from 300 to 1600 µg/L. These concentrations are considered to represent an upper estimate of concentrations that could be encountered in mine water following paste backfill placement. Ferrous sulphate (as $Fe(SO_4)\cdot 7H_2O$) was added to the spiked mine water samples and the resulting hexavalent Cr concentrations were assessed using spectrophotometric methods. All experiments were carried out at 4ºC, but pH and total suspended solids (TSS) conditions were varied to assess whether these variables would limit Cr reduction rates.

The results of the experimental program indicate that Cr(VI) is effectively reduced within less than 30 minutes through the addition of ferrous sulphate when the ratio of Fe(II) to Cr(VI) is at least 8 (Figure 5-3). Effective reduction (98% to 100% reduction) was observed at all TSS concentrations and pH conditions. Therefore, if elevated Cr(VI) concentrations are observed within specific areas of the underground mine, direct treatment with ferrous sulphate is expected to be an effective mitigation strategy. A figure showing the concentration of $Fe(SO_4)\cdot 7H_2O$ required to reduce Cr(VI) to Cr(III) for a given Cr(VI) concentration and Fe(II) to Cr(VI) ratio is provided for reference should this be implemented at site. Based on the experimental program results, the rate of Cr(VI) reduction is rapid and thus any Cr(VI) in mine water should be reduced before reaching the WTP where the Cr(III) generated will be removed.

Figure 5-3: Percent reduction of hexavalent Cr over variable Fe(II) to Cr(VI) ratios for samples having variable total suspended solids (TSS) concentrations.

Figure 5-4: Concentration of ferrous sulphate heptahydrate required for reduction of Cr(VI) at specified Cr(VI) concentrations and Fe(II) to Cr(VI) ratios (expressed as an excess of Fe(II)). The experiments carried out indicate that effective reduction is achieved when the concentration of Fe(II) is at least 8× that of Cr(VI).

5.3 SHOTCRETE

Shotcrete is used at the Brucejack Mine for structural reinforcement of underground mine headings to prevent tunnel failure and to help ensure the safety of underground workers, and for construction of fences to retain cemented paste within excavated stopes. Shotcrete used in the underground is a mixture of Portland cement, aggregate, accelerant and water; therefore, water-soluble hexavalent Cr (approximately 2 mg/kg) is introduced to the shotcrete mixture from the Portland cement. A study of the release and mitigation of hexavalent Cr from shotcrete application at the Brucejack Mine indicates that ferrous sulphate will be effective in reducing the release of water-soluble hexavalent Cr to mine water. A brief overview of the study is summarized below. Additional details are described in Appendix 4.5-5 of the 2015 Annual Report.

Lab experiments indicated shotcrete cured for 24 hours released approximately 0.03 mg/kg hexavalent Cr, a reduction of more than 98% compared to the maximum amount available in the uncured product. The lab study evaluated the effect of ferrous sulphate added to the dry shotcrete mixture prior to the addition of water. Ferrous sulphate converts hexavalent Cr to Cr (III) hydroxide, which is not water soluble in the elevated pH conditions of the wet shotcrete mixture, thereby preventing Cr release to the liquid phase. Shotcrete mixtures were amended with 0.2% and 0.5% (of the cement by mass) ferrous sulphate, resulting in loading reductions of the maximum water-soluble hexavalent Cr to 0.7 mg/kg and 0.6 mg/kg, respectively (reductions of approximately 65% to 70% compared to the non-amended shotcrete product). For cured shotcrete amended with ferrous

sulphate, the hexavalent Cr release was 0.01 mg/kg and 0.02 mg/kg, also lower than the release rate for the non-amended shotcrete (approximately 35% to 65% reduction).

Following this testwork, Pretium refined shotcrete application methods and began using a ferrous sulphate-amended shotcrete product (starting on March 1, 2016). The amount of ferrous sulphate added constitutes approximately 0.2% of the cement and has proven to be effective at reducing concentrations of hexavalent Cr in mine water. Pretium has also implemented best practices for source control to minimize the amount of uncured shotcrete that comes into contact with mine water.

6 MONITORING

6.1 OVERVIEW

The placement of cemented paste backfill into mined-out stopes began in August 2017. The backfill placement process and the associated monitoring was undertaken in a controlled manner to minimize any potential environmental risks associated with hexavalent Cr. The overall aims of the monitoring program are to assess Cr behaviour and ensure that Cr associated with the various mine components can be managed appropriately. The program consists of routine measurements for the following components:

- Paste backfill cement: to ensure that Cr contents in the cement provided by the supplier are within the anticipated range (25-50 ppm). An SOP for cement sampling procedures is provided in Appendix 6-1 of this document.

- Tailings solids: to assess the variability of Cr contents in tailings and ensure that concentrations are within the range expected based on prior static test results. An SOP for tailings solids sampling procedures is provided in Appendix 11 of the ML/ARD Management Plan.

- Paste backfill solids: to assess the variability of Cr contents in cemented paste backfill and ensure that the concentrations are within the expected range. Sampling procedures are outlined in Appendix 11 of the ML/ARD Management Plan.

- Seepage from backfilled stopes: to evaluate soluble Cr loads associated with backfilled stopes and verify water quality model assumptions. Sampling protocols are outlined in Appendix 6-2 of this document.

- Sump water: to assess changes in Cr in underground mine water as paste backfilling proceeds. A general SOP for sump water sampling is provided in Appendix 6 of the ML/ARD Management Plan, with Cr specific instructions provided in Appendix 6-2 of this document.

- WTP influent: to evaluate Cr inputs to the water treatment plant and ensure that D-Cr is below the WTP influent management trigger value of 10 µg/L. An SOP for WTP sampling is provided in Appendix 10 of the ML/ARD Management Plan, with Cr specific instructions provided in Appendix 6-2 of this document.

- WTP effluent: to assess Cr discharged to Brucejack WRTSF from the water treatment plant and ensure that T-Cr is below the WTP effluent trigger specified in Permit 107835 (20 µg/L). Sampling protocols are outlined in Appendix 10 of the ML/ARD Management Plan and Appendix 6-2 of this document.

- Brucejack WRTSF at BJ 3.10: to ensure that Cr is meeting BC Freshwater Aquatic Life guidelines (T-Cr < 9 µg/L and Cr(VI) < 1 µg/L). Sampling protocols are outlined in the Water Quality Sampling for Compliance Site BJ 3.10 SOP.

The ongoing Cr monitoring program, including the sampling frequencies and parameters measured for the various mine components, is summarized in Table 6-1.

Table 6-1: Overview of the Brucejack Mine Chromium Monitoring Program

Mine Component	Monitoring Frequency	Parameters Measured		
		T-Cr	D-Cr	Cr(VI)
Paste backfill cement	Quarterly	√	-	-
Tailings solids	Quarterly	√	-	-
Paste backfill solids	Quarterly	√	-	-
Seepage from paste backfilled stopes	Two stopes per year with a minimum of 5 samples collected at each stope[1]	√	√	√
Seeps and sump water	Quarterly	√	√	-
WTP influent	Twice per month	√	√	Only if D-Cr is > 10 µg/L
WTP effluent	Twice per month	√	√	Only if T-Cr is > 20 µg/L
Brucejack WRTSF at BJ 3.10	Weekly	√	√	Only if D-Cr is > 1 µg/L

Notes: 1 – until such time as data validate source term assumptions or a data set sufficient to define updated source terms has been acquired.

6.2 MONITORING RESULTS

The full set of monitoring results for Cr along with other parameters are presented on an annual basis in the Brucejack Mine annual reports. The sections below provide a summary of monitoring results for cement binder, tailings solids, paste backfill solids, seepage from backfilled stopes, seeps and sumps, WTP influent and effluent, and Brucejack WRTSF at BJ 3.10.

6.2.1 Cement

Of the 23 samples that have been analysed since the paste backfilling operation was initiated, only 1 sample was above the expected range (25-50 ppm) with a value of 61 ppm. The total Cr content of cement binder samples analysed ranged from 15-61 ppm, with a median value of 23 ppm.

6.2.2 Tailings Solids

Samples of thickened tailings are collected from the underflow of the thickening tank and are representative of tailings used to generate cemented paste backfill and of tailings discharged to Brucejack WRTSF. The Cr content of the 29 representative samples collected since the mill was commissioned ranged from 8-42 ppm with a median value of 29 ppm.

6.2.3 Paste Backfill Solids

Solid phase element analysis has been conducted on 23 samples of cemented paste collected since paste backfilling was initiated. The Cr content of the cemented paste ranged from 9-31 ppm with a median value of 18 ppm. The results of tailings solids and paste backfill solids sampling indicates that the Cr content of the cement binder has not significantly affected the Cr content of the cemented paste.

6.2.4 Seepage from Backfilled Stopes

Seepage from backfilled stopes was monitored approximately weekly during the paste backfill phase in period (August to November 2017). Following the initial phase in period, seepage has been monitored a minimum of monthly to the end of 2018. Typically, stopes where backfilling operations were in progress or had recently been completed were selected for monitoring; however, a time series was conducted on stope 1320-18 to investigate the rate at which Cr concentrations decreased following completion of backfilling operations.

Immediately after backfilling, upwards of 75% of Cr in seepage from backfilled stopes is present in the dissolved form (Figure 6-1). The proportion of dissolved Cr decreases rapidly following completion of backfilling operations: one month after backfilling was completed in stope 1320-18, 27% of Cr was present in the dissolved form. The majority of dissolved Cr in seepage from backfilled stopes is present as Cr(VI); however, the speciation of Cr in low concentration samples cannot be assessed due to laboratory detection limits. The limit of detection for dissolved Cr is 0.1 µg/L whereas the limit of detection for dissolved Cr(VI) is 1 µg/L.

Total Cr concentrations in seepage ranged from 0.42-632 µg/L with a median of 22 µg/L, dissolved Cr concentrations ranged from 0.1-131 µg/L with a median of 13.3 µg/L and dissolved Cr(VI) concentrations ranged from 0.5-135 µg/L with a median of 11.7 µg/L. Concentrations of dissolved Cr(VI) decreased below the limit of detection in seepage from stope 1320-18 within 34 days of backfill completion (Figure 6-2).

Figure 6-1: Cr monitoring results for seepage from backfilled stopes.

Figure 6-2: Cr monitoring results for seepage from Stope 1320-18.

6.2.5 Seeps and Sumps

Monitoring of underground mine sumps and seeps is conducted quarterly. Seeps with low pH (<6) and elevated conductivity (>200 µS/cm) are sampled when they are encountered whereas sumps are sampled quarterly. One seep sample has been collected since paste backfill placement commenced.

The total Cr and dissolved Cr concentrations in the seep sample were below the limit of detection (LOD).

Samples have been collected from the ten active sumps during five sampling events since paste backfill placement commenced. The slimes content of the sumps is typically high and the total Cr concentrations correspondingly elevated. The median total Cr concentration in sumps was 39 µg/L and concentrations ranged from 0.44-329 µg /L. Dissolved Cr concentrations in sump water are much lower with a median value of 0.47 µg /L and a range of 0.1-26 µg /L. Of the 47 sump samples collected since initiation of paste backfill operations, dissolved Cr concentrations were below the LOD in 18 samples and one sample had dissolved Cr concentrations greater than the WTP influent trigger of 10 µg/L.

6.2.6 WTP Monitoring

WTP influent and effluent water quality is analysed twice a month for various parameters including T-Cr and D-Cr. Monitoring results spanning the time period since paste placement began (August 2017 through September 2018) are presented in Figure 6-3. The WTP influent D-Cr concentrations during this time period ranged from 0.1 to 5.3 µg/L, well below the WTP influent trigger value of 10 µg/L. Dissolved and total Cr concentrations in WTP effluent ranged from 0.1 to 2.4 µg/L, also well below the WTP Effluent trigger level of 20 µg/L. The observation of lower D-Cr in WTP effluent, as compared to influent suggests that a portion of the D-Cr is in the Cr(III) form and treated by the WTP.

Figure 6-3: Cr concentrations in WTP influent (D-Cr) and effluent (D-Cr and T-Cr) as compared to Cr management trigger levels. Paste backfilling of mined-out stopes began in August 2017.

6.2.7 Brucejack WRTSF at BJ 3.10

Brucejack WRTSF water quality at BJ 3.10 is measured on a weekly basis for the full suite of parameters including T-Cr and D-Cr. BJ 3.10 water quality must meet BC Freshwater Aquatic Life (FWAL) guidelines for Cr(III) (9 µg/L) and Cr(VI) (1 µg/L). Monitoring data for D-Cr, as compared to water quality predictions are presented in Figure 6-4. The monitoring results show that samples are well below the Cr(VI) BC FWAL guideline, with most samples having D-Cr concentrations at the detection limit (0.1 µg/L) and maximum D-Cr values of up to 0.16 µg/L.

Figure 6-4: Dissolved Cr concentrations in Brucejack WRTSF at monitoring station BJ 3.10, as compared to modelled Upper Case and Base Case water quality predictions and the BC FWAL maximum guideline for Cr(VI) (1 µg/L). Note that most samples have concentrations equal to the analytical detection level for dissolved Cr (0.1 µg/L).

7 ADAPTIVE CHROMIUM MANAGEMENT

7.1 OVERVIEW

Management of Cr at Brucejack Mine is achieved through an adaptive approach which includes the following key elements:

- Research and experimental test programs to better understand the risk associated with Cr(VI) at Brucejack Mine;
- Cr-specific monitoring programs for the various mine components (Table 6-1; Section 6);
- Cr management triggers and response plans for WTP influent, WTP effluent, and Brucejack WRTSF water quality at BJ 3.10;
- Investigations when monitoring data shows Cr concentrations above management trigger level or the anticipated range;

- Identification and implementation of mitigation measures as necessary;
- Delineation of the roles and responsibilities of Pretium staff; and
- Annual Review of the CMP.

The details of the experimental and monitoring programs are outlined in Section 5 and Section 6, respectively. The other key elements of Cr management at Brucejack Mine are described in the sections below.

7.2 CHROMIUM MANAGEMENT TRIGGERS

Chromium is monitored and managed at various locations at Brucejack Mine as described in Section 6. Chromium management triggers have been specified for WTP influent, WTP effluent and Brucejack WRTSF water at BJ 3.10. The trigger levels and actions required following a trigger exceedance for each of these monitored components are outlined below.

7.2.1 WTP Influent

The Cr trigger level for WTP influent is specified for D-Cr and is 10 µg/L. In the event of a trigger level incident where D-Cr levels in WTP influent exceed 10 µg/L, Pretium will follow the steps outlined in the Cr Trigger Response Plan Flow Chart for WTP influent (Figure 7-1). The first step will be to determine the speciation of Cr and verify the initial result through the collection of additional samples. If the concentration of Cr (VI) in the follow up sample is greater than 10 µg/L, then the next step in the process will be to initiate an investigation to identify the cause of the exceedance (Section 7.3). Following the investigation, appropriate mitigation measures (Section 7.4) will be identified and implemented, as necessary. The efficacy of the mitigation selected will be determined based on follow up monitoring results.

The details of any WTP influent Cr trigger incident and the ensuing investigation, mitigation and follow up monitoring results will be reported in the Annual Reclamation Report.

Figure 7-1: Cr Trigger Response Plan Flow Chart for WTP Influent

7.2.2 WTP Effluent

The Cr trigger level for WTP effluent is specified for T-Cr and is 20 µg/L. In the event of a trigger level incident where T-Cr levels in WTP effluent exceed 20 µg/L, Pretium will follow the steps outlined in the Cr Trigger Response Plan Flow Chart for WTP effluent (Figure 7-2). The first step will be to recirculate WTP effluent to the contact water pond (CWP), as per Condition 1.2.4 in PE 107835 and to collect a follow up sample to verify the initial result and to determine the speciation of Cr. If the concentration of T-Cr in the follow up sample is less than 20 µg/L, then WTP effluent recirculation to the CWP can be discontinued and regular monitoring protocols can be resumed. If the concentration of T-Cr in the follow up sample is greater than 20 µg/L, then the next step in the process will be to initiate an investigation to identify the cause of the exceedance (Section 7.3). Following the investigation, appropriate mitigation measures will be identified and implemented, as necessary. The efficacy of the mitigation selected will be determined based on follow up monitoring results.

The details of any WTP effluent Cr trigger incident including the duration of the recirculation to the CWP along with the ensuing investigation, mitigation and follow up monitoring results will be reported in the Annual Reclamation Report.

Figure 7-2: Cr Trigger Response Flow Chart for WTP Effluent

7.2.3 Brucejack WRTSF at BJ 3.10

Brucejack WRTSF water quality as measured at BJ 3.10 is required to meet BC FWAL guidelines for total trivalent Cr [Cr(III)] (9 µg/L) and total hexavalent Cr [Cr(IV)] (1 µg/L). Hexavalent Cr is soluble and thus the BJ 3.10 Cr trigger is specified for D-Cr and equal to 1 µg/L. In the event of a trigger level incident where D-Cr at BJ 3.10 exceeds 1 µg/L, Pretium will follow the steps outlined in the Cr Trigger Response Plan Flow Chart for WTP effluent (Figure 7-3). The first step will be to determine the speciation of Cr and verify the initial result through the collection of an additional sample. If the concentration of Cr (VI) in the follow up sample is greater than 1 µg/L, then the exceedance will be reported to the B.C. Ministry of Environment, in accordance with the requirements of PE-107835. The next step in the process will be to initiate an investigation to identify the cause of the exceedance (Section 7.3). Following the investigation, appropriate mitigation measures will be identified and implemented, as necessary. The efficacy of the mitigation selected will be determined based on follow up monitoring results.

The details of any WTP influent Cr trigger incident and the ensuing investigation, mitigation and follow up monitoring results will be reported in the Annual Reclamation Report.

Figure 7-3: Cr Trigger Response Flow Chart for Brucejack WRTSF at BJ 3.10

7.3 INVESTIGATION

In the event that monitoring results indicate Cr concentrations for a particular mine component that are higher than the anticipated range or a specified trigger level (Section 7.2), an investigation will be carried out. The investigation will be undertaken to identify the root cause of elevated Cr. The investigation may include, but will not necessarily be limited to, the following:

1. Verification of results through collection of additional samples to be analyzed for T-Cr, D-Cr and Cr(VI) where applicable.
2. Determining the potential cause(s) in consultation with mine personnel or cement suppliers, including consideration of whether elevated Cr may have resulted from routine operations or from any unusual or extraordinary circumstances.
3. A visual inspection of the underground mine to determine whether there is significant seepage from backfilled stopes, or if there are any other likely causes of elevated Cr concentrations in the underground mine (these may include extensive use of shotcrete, or intensive grouting of drillholes, for example).
4. Expansion of the monitoring program to identify the source of elevated Cr. This could include collection of mine water samples in the vicinity of recently backfilled stopes and/or other areas where cement has been used. Samples will be sent to an external accredited laboratory for analysis, with the intention that the results will allow Pretium to confirm the degree to which Cr concentrations are elevated, as well as the location at which Cr was introduced into mine water.
5. An assessment of the severity (maximum Cr concentration), temporal and geographic extent of the occurrence, and likelihood of recurrence.
6. Recommendations for immediate source control and mitigation.

The results of the investigation will be documented and described in the Annual Reclamation Report. Documentation of the incident may include, but will not necessarily be limited to, the following information:

- A description of the incident;
- A summary of the source control measures that were implemented;
- A description of the investigation that was undertaken;
- An assessment of the root cause; and
- Recommended action.

7.4 MITIGATION

In the case where elevated Cr concentrations are encountered, corrective action may be implemented to minimize the effect on the receiving environment, in both the short-term, and throughout the Operations phase. Mitigation will be determined based on the outcome of the investigation. The following sections describe potential source control measures and treatment options.

7.4.1 Source Control

Options for source control may include, but are not limited to:

- Water management strategies (e.g., storage, diversion, dilution) to minimize Cr concentrations in mine water discharge;
- Modifying backfill placement methods or otherwise preventing or minimizing the release of leachate from backfilled stopes.
- Minimizing seepage from backfilled stopes by plugging any leaks identified;
- Amending mine water with ferrous sulphate (refer to Figure 5-4) in target areas to reduce the Cr concentration, prior to pumping the mine water to the WTP.

Corrective actions will be implemented promptly and reviewed for effectiveness. The Environmental Manager is responsible for ensuring that corrective actions are implemented, and reviewed, until an incident is deemed to be resolved.

7.4.2 Treatment

If the results of the investigation indicate that elevated Cr is likely to be a recurring problem, or if the problem persists for unforeseen reasons, it may be necessary to mitigate through implementation of treatment measure on an ongoing basis. The decision to implement treatment will be made based on a review of the available data by the Environmental Manager and Chief Mining Engineer/Manager of Technical Services.

Treatment measures may include, but are not necessarily limited to, the following:

1. Adding ferrous sulphate into the cemented paste backfill mixture.
2. Modification of the WTP treatment process to reduce the concentration of Cr(VI).

Pretium's preferred treatment option, should it be required, is the addition of ferrous sulphate to the paste backfill within the paste plant prior to placement underground (option 1). The results of testwork presented in Section 5.1 indicate that a dosage of 1% (of the cement by mass) is effective at reducing the amount of leachable hexavalent Cr.

The current design for paste backfill generation includes a paste mixer where the cement binder is combined with the thickened tailings received from the mill. The requisite amount of ferrous sulphate would be introduced to the paste mixer with the cement. The homogenized paste mixture would then be pumped to the various stopes to be backfilled. Hydrostatic bulkheads will be placed at the base of the stopes to contain the paste backfill and minimize seepage.

While treatment to reduce Cr(VI) within the WTP (option 2) is feasible, it will be necessary to design the treatment process, evaluate the proposed treatment process through bench tests or other suitable means, incorporate the modifications into the WTP and fully commission the updated WTP. This work will only be initiated should other mitigation options prove insufficient or ineffective in limiting the concentration of Cr(VI) in WTP effluent.

7.5 Roles and Responsibilities

Effective Cr management will require coordinated action by members of the mine engineering and environmental teams. Key tasks include: (i) selecting and implementing mitigation and adaptive management measures, as necessary (ii) transporting and handling ferrous sulphate in accordance with applicable health, safety and environmental requirements; (iii) incorporating the ferrous sulphate into the paste backfill (should this become necessary) or mine water in the appropriate amount so as to mitigate Cr(VI) leaching; and (iv) monitoring, to ensure that the CMP is effective.

General roles and responsibilities are outlined below, recognizing that some refinement and further delineation may ultimately be required as the CMP is fully implemented. The successful implementation of the CMP will require oversight by the Chief Mine Engineer/Manager of Technical Services and Environmental Manager, and may ultimately require action by the Mill Manager.

Key responsibilities for each are outlined as follows:

1. The Mill Manager will be responsible for incorporating ferrous sulphate in the preparation of paste backfill, should this be necessary;
2. The Chief Mine Engineer/Manager of Technical Services will be responsible for placement of paste backfill in accordance with this Plan;
3. The Mill Manager will be responsible, should it become necessary, to incorporate a treatment process for reducing Cr(VI) concentrations in mine water; and
4. The Environmental Manager will be responsible for monitoring and implementation of mitigation measures, as necessary, so as to ensure that treated mine water complies with regulatory requirements prior to discharge to the receiving environment.

These Managers will be responsible to ensure the development and implementation of standard procedures for the various aspects of Cr management for which they are responsible. More specifically, standard procedures would be adopted for:

- Transportation, storage and handling of ferrous sulphate, at the Mine Site, and within the facilities in which it is used.
- Operational procedures for dosing and mixing of ferrous sulphate within the paste plant.
- Operational procedures for paste placement in the underground workings, so as to avoid and minimize the release of leachate.
- Operational procedures for monitoring within the underground workings and the WTP, as appropriate.

It is understood that the managers to whom responsibilities are assigned may delegate certain responsibilities and actions to other personnel and/or contractors, and that specific roles and responsibilities will be further defined in due course.

7.6 ANNUAL REVIEW

The implementation and effectiveness of the CMP, including the results of the monitoring program and any exceedance of the trigger threshold, will be evaluated through ongoing and annual review of monitoring results. The annual review will be led by the geochemistry Qualified Professional.

8 CONCLUSIONS

Monitoring will be undertaken in accordance with this plan to verify water quality predictions, which indicate that while hexavalent Cr is expected to be leached from cemented paste backfill, concentrations are not expected to exceed BC FWAL guidelines in the receiving environment.

In the event that Cr concentrations exceed any of the trigger threshold levels as specified in Section 7.2, an investigation will be undertaken to identify the cause and suitable remedies. Mitigation may include localized efforts to prevent leachate from being released from backfilled stopes or the addition of ferrous sulphate to mine water and/or the paste backfill mixture within the paste plant. Mitigation through ferrous sulphate amendment of mine water or paste backfill is expected to reduce the concentration of hexavalent Cr in mine contact water to levels that are protective of the receiving environment. Should these mitigation strategies prove ineffective for any reason, Cr(VI) treatment will be incorporated into the existing water treatment plant process.

The effectiveness of this CMP will be periodically evaluated by the geochemistry Qualified Professional and the plan adapted to include detailed operational procedures, as necessary.

APPENDIX 6-1 SOP: WATER QUALITY SAMPLE COLLECTION FOR DETERMINATION OF CHROMIUM CONCENTRATIONS AND SPECIATION

PRETIVM		BJ-ENV-SOP-011 Underground Chromium Sample Collection	
Owner: Colleen Atherton	**Approver**: Robin McCall/ Torence Sandhals/ Jason Gabora	**Revision Number**: 3	**Creation Date**09/14/2018
			Revision Date: Feb 4, 2019

Objective

To provide guidance for Pretivm personnel for collection of underground water quality samples in support of the Chromium Management Plan (CMP).

Scope

Activities related to collection of Cr speciation samples during monitoring of paste backfill. Samples will be collected in the underground workings adjacent to recently backfilled stopes. Two stopes are to be monitored each year until such time as data validate source term assumptions or a data set sufficient to define updated source terms has been acquired. Six samples will typically be collected from each stope following completion of backfill placement. Samples will be collected roughly on Day 1, Day 3, Day 7, Day 14, Day 28 and Day 180.

The sample volumes, bottle types and preservation methods described in this SOP are also applicable to Cr speciation samples collected from WTP influent, WTP effluent and BJ 3.10 as required following exceedance of the triggers identified in the CMP.

Health, Safety & Reclamation Code of BC

- 1.11.1 - Training
- 1.8.2, 1.8.3, 1.8.4, 1.8.5 - Personal Protective Equipment
- 2.13 - WHMIS

Definitions

- BCMDG: British Columbia Mine Design Guideline (i.e., cost-effective low-level detection limits)
- CMP: Chromium Management Plan
- DI water: De-ionized water
- DO:Dissolved oxygen
- Field parameters: DO, pH, and conductivity
- ML/ARD: Metal leaching and acid rock drainage
- Muck: blasted underground rock
- Paste Fence: plug constructed to retain cemented paste within the stope
- PPE: Personal Protective Equipment which includes hardhat with reflective stripes, steel toed boots with metatarsal protection, safety glasses, W65 self-rescuer, cap lamp, belt, and nitrile gloves.
- QA/QC: Quality assurance and quality control
- TSS: Total suspended solids

Preparation

Hazards

- Slips and falls.
- Air quality.
- Unstable ground.
- Noise.
- Working near machinery.
- Working with hazardous chemicals.

Tools

- PPE
  - Underground hi-vis coveralls
  - Hart hat
  - Blue blinking light attached to back of hard hat
  - Miners light
  - W 65 self-rescuer
  - Miners belt
  - Clear safety glasses
  - Underground steel toe boots
  - Respirator
- pH/conductivity/DO probe.
- Nitrile gloves.
- Field notebook and pencil.
- Sample labels.
- Camera.
- Cooler containing
  - Disposable syringes and disposable 0.45 µm disc filters.
  - Bottles described in Table 1.
  - Preservatives described in Table 1.
- QA/QC supplies as required
  - Full additional bottle and preservative set as described in Table 1 for field blank.
  - Additional D-Cr (VI) and D-Metals bottles and preservative for duplicate.
  - 1 L of DI water for field blank.

Requirements

- Trained and qualified to conduct water-quality sampling.
- Knowledge of CMP and monitoring program.
- Underground orientation.

Job Step

1. Contact Mine Captain

- Contact Mine Captain to identify an appropriate stope and to arrange transportation.
- A stope with no accumulation of water between the paste fence and the muck pile prior to paste placement should be selected, if possible. Ideally, the sample will be composed entirely of paste bleed water, with no sources external to the stope.

2. Prepare sampling equipment

- Organize and label bottles with the stope ID, e.g., 1320-28. Some stopes will have an alpha-numeric ID, e.g., 1320-28A.
- Calibrate probe for field parameters.
- Review sample collection methods in BJ-ENV-SOP-028 “General Water Sampling” if required.

3. Collect samples

- Samples should be collected as close to the paste fence as possible. Safety considerations may restrict access to the outside of the safety barricade (composed of muck).
- The sample should be collected from running water if possible, but may be collected from standing water if necessary, e.g., from water collected behind the muck barricade.
- Put on nitrile gloves. Replace gloves if they become contaminated and between each sample.

- Fill and preserve bottles as specified in Table 1. Use a new syringe and disc filter for each sample.
- **Collect QA/QC samples during the first sampling event for each stope.**
- Collect measurements of field parameters on a separate aliquot of sample.
- Record observations in your field notes, such as:
  - Date and time.
  - Field parameters.
  - Location of sample collection, e.g., at paste fence, in front of muck barricade, behind muck barricade.
  - Whether the sample was collected from standing or running water.
  - Approximate flow rate.
  - Water clarity and odor.
  - Photographs.

Table 1: Summary of Bottles, Preservation, and Analytical Parameters for Samples

Bottle and Volume	**Field Preservation**	**Field Filter**	**Refrigerate (4°C)**	**Indicate on Bottle**	**Parameter(s) to be indicated on COC**
500 mL plastic	None	No	Yes	General Chemistry	General Chemistry: **pH, TSS, and anions**
60 mL plastic	HNO3	No	Yes	T-Cr	Total chromium
60 mL plastic	HNO3	Yes	Yes	Dissolved Metals	MET-D-BCMDG-VA*
60 mL plastic	NaOH	Yes	Yes	D-Cr(VI)	Dissolved hexavalent Cr*
125 mL amber	H2SO4	No	Yes	Total Nutrients	Ammonia and T-N

Notes: Parameters listed in **bold** must be indicated on the COC for the analytical laboratory.

*Duplicate sample to be collected during first sampling event.

4. QA/QC Samples

- Collect one duplicate using the filtering and preservation procedure described in Table 1 and Step 3. This sample is identified by -98, e.g., 1320-28-98.
- Collect duplicates only for parameters identified in Table 1.
- Collect one blank by filling an additional set of bottles with DI water using the filtering and preservation procedure described in Table 1 and Step 3. This sample is identified by -99, e.g., 1320-28-99.

5. Complete COC

- Complete COC as per example in Appendix 1.

6. Ship samples

- Ship samples to the analytical Laboratory (currently ALS Global in Burnaby, BC).
- Use adequate ice packs to ensure the samples arrive at the laboratory <10°C.

APPENDIX 6-2 SOP: PASTE BACKFILL CEMENT SAMPLE COLLECTION FOR DETERMINATION OF CHROMIUM CONCENTRATIONS

PRETIVM		BJ-ENV-SOP-042 Cement Binder Sampling	
Owner: Colleen Atherton	**Approver**: Torence Sandhals	**Revision Number**: 3	**Creation Date**: Feb 23, 2017 **Revision Date**: Jan 24, 2019

Objective

To provide guidance for Pretivm personnel for collection of cement binder (Terraflow 90) samples in support of the Chromium Management Plan (CMP).

Scope

All activities related to collection of cement binder samples.

Health, Safety & Reclamation Code of BC

- 1.11.1 Training
- 1.8.2, 1.8.3, 1.8.4, 1.8.5 Personal Protective Equipment
- 2.13 WHMIS

Definitions

- CMP: Chromium Management Plan
- COC: Chain of Custody
- PPE: Personal Protective Equipment which includes hardhat with reflective stripes, steel toed boots, safety glasses, hearing protection and nitrile or vinyl gloves and respirator.
- QA/QC: Quality assurance and quality control

Preparation

Hazards

- Slips and falls
- Working near heavy machinery
- Noise
- Pinch points
- Contact with alkaline material
- Faulty PPE

Tools

- PPE
  - Hi-vis vest
  - Hard hat
  - Steel toed boots
  - Safety glasses
  - Hearing protection
  - Nitrile or vinyl gloves.
- Field notebook, pen and markers
- Sample bags and sample tags
- COC, offsite removal form

Requirements

- Trained and qualified to conduct cement sampling
- Knowledge of CMP and monitoring program

Job Step

1. **Field Preparation**
   - Ensure appropriate number of sample bags and sample tags are available to collect cement binder samples
   - The Environmental Scientist will prepare a sample bag by filling out the SGS sample tag and placing it in the sample bag.
   - The Environmental Scientist will deliver the sample bag to the Operator in charge of filling the isotainers from the silo at Knipple Camp.
2. **Sampling**
   - The Operator will obtain a sample of cement binder by accessing the top hatch using the stairway and platform.
   - The Operator will place at least 500 g of cement binder in the bag provided by the Environmental Scientist
   - When instructed by the Environmental Scientist, the Operator will obtain a 1500 g aliquot which will be separated into two QA/QC samples by the Environmental Scientist (one QA/QC sample for every 10 samples).
   - The Environmental Scientist will retrieve the sample bag from the Operator.
3. **Description of QA/QC Samples**
   - Duplicate samples must be collected for every 10 samples for QA/QC purposes.
   - This is achieved by collecting a 1500g sample, instead of the typical 500 g sample.
   - The Environmental Scientist will take a 500g sub-sample from the 1500 g sample after it is collected by the Operator and will place the sub-sample in a separate sample bag with a unique sample tag number.
   - After sub-sampling, the remaining 1000 g will be the laboratory duplicate. The sample tag must have DUP added to the tag number e.g., B00000001-DUP. This sample will be split by the lab technician and analyzed for T-Cr.
4. **Record Field Notes**
   - Date and time.
   - Name of samplers.
   - Sample IDs.
   - Observations.
5. **Shipping and Analytical Parameters**
   - Complete the COC as per the example provided in Appendix I.
   - All samples are to be shipped via courier to an accredited laboratory (currently SGS Laboratories in Burnaby, B.C.) for total chromium (T-Cr) analysis.
   - In addition to the COC, complete an Offsite Removal Form as shown in Appendix II.

AMP	Adaptive Management Plan
BC	British Columbia
FWAL	Freshwater Aquatic Life
LOM	Life of Mine
PAG	Potentially Acid Generating
POPC	Parameter of Potential Concern
ML/ARD	Metal Leaching / Acid Rock Drainage
WRTSF	Waste Rock and Tailings Storage Facility
WTP	Water Treatment Plant

1 INTRODUCTION

1.1 PURPOSE

The purpose of this Adaptive Management Plan (AMP) is to outline adaptive management for water quality that develops in the underground workings (the 'mine pool') during the Closure phase of Brucejack Gold Mine when the mine will be flooded. Waste rock and paste backfill placed in the mine over operations, as well as the mine wall exposures, are expected to release chemical loads to the mine pool as they are submerged. Estimates of these loads and the associated peaks in concentrations have been incorporated into the site wide water quality model (Lorax 2020b). This AMP provides details with respect to the current plan for managing the predicted water quality at Closure, additional management strategies that could be implemented as required, and monitoring programs developed to refine understanding of potential water quality at Closure and the groundwater flow system.

1.2 PERFORMANCE OBJECTIVES

The performance objectives will be evaluated based on the underground mine water quality both during Operations (to revise predictions for mine pool water quality) and during the Closure phase when management strategies outlined in this plan will be implemented.

The main goal of this plan is to achieve water quality of the mine pool, once flooded, that will not lead to exceedances of relevant water quality guidelines or approved discharge limits in the receiving environment (Brucejack Creek) and no longer requires active treatment.

1.3 SCOPE

The scope of this plan covers monitoring plans throughout Operations and Closure mine phases relevant to water quality of the underground mine, as well as a description of contingency options that could be implemented during reflooding of the mine.

1.4 RELEVANT LEGISLATION AND REGULATIONS

This plan has been prepared as required by *Mines Act* Permit M-243 Condition D.5 and in accordance with the information requirements outlined in Section 3.3 of *Environmental Management Act* Effluent Permit 107835 (PE-107835). The water quality, water balance and groundwater models informing this plan have been revised to include the most up-to-date geochemistry, hydrology and hydrogeology data (Lorax 2020 a,b,c).

During the Operations phase, the waste rock and tailing storage facility (WRTSF) receives all mine-affected inputs, and thus monitoring station BJ 3.10 at the outlet to the WRTSF is the mine's final compliance location where discharge limits specified in Section 1.1.1 of PE-107835 apply. However, during the Post-closure phase, once the mine is flooded, the majority of groundwater flow paths from the underground mine discharge to the upper reaches of Brucejack Creek between the WRTSF outlet

and BJ 2.62. It is expected that BJ 2.62 will become the regulated final discharge point at Closure. The current PE-107835 BJ 3.10 discharge limits and applicable BC FWAL water quality guidelines for Brucejack Gold Mine are presented in Table 1-1.

Table 1-1. PE-107835 Discharge Limits and Applicable BC FWAL Guidelines

Parameter	Units	BC FWAL Guidelines		Effluent Discharge Limit
		Long-term	Short-term	
Ammonia	mg-N/L	NA	NA	4.0
Nitrite	mg-N/L	NA	NA	0.24
Nitrate	mg-N/L	NA	NA	11.5
Chloride	mg/L	150	600	NP

Zinc-T	mg/L	0.0075	0.033	NP

Notes: BC FWAL = BC water quality guidelines for protection of freshwater aquatic life. Hardness dependent guidelines calculated using the baseline median hardness of 28 mg/L as $CaCO_3$. Ammonia guidelines calculated using a pH of 8.0 and temperature of 15°C.
Copper guidelines calculated using the BC biotic ligand model. Inputs to the model were the 2019 annual averages measured at BJ 3.10 of pH 7.9, DOC 0.5 mg/L, Alkalinity 52 mg/L, Ca 24 mg/L, Mg 1.2 mg/L, Na 22 mg/L, K 7.7 mg/L, SO_4 46.5 mg/L, and Cl 1.6 mg/L. A summer temperature of 10 °C was used. The default of 10% of DOC present as humic acid was used. Chromium guideline is for Cr(VI). NP=none proposed. NA=not applicable because the WQG is superseded by the discharge limit.

2 ADAPTIVE MANAGEMENT FOR MINE POOL AT CLOSURE

2.1 OVERVIEW

Brucejack Gold Mine operations will continue through to the end of 2032, with closure of the mine and its ancillary facilities scheduled to commence in January 2033 and continue over a total period of approximately three years, as described in the 2020 Mine Plan and Reclamation Program Update (Pretivm, 2020c). Flooding of the mine is planned to start in January 2033 with water in the mine predicted to flood to an ultimate level of approximately 1400 masl (varying seasonally between 1394 and 1410 masl) (Lorax 2020a).

The groundwater model developed for the site (Lorax 2020a) predicts that natural groundwater infiltration would flood the mine within approximately 2.5 years. However, once the water level reaches 1360 masl, after approximately 21 months, contact water from the underground mine is predicted to begin reporting to Brucejack Creek via subsurface pathways. It will be necessary to manage water quality in the underground mine pool throughout mine flooding and potentially beyond, to achieve regulatory compliance in the receiving environment (Section 1.4). The adaptive management strategies available to Pretium Resources Inc. (Pretivm) and which are described in this plan, include water treatment, control of the flooding rate and control of the discharge from the mine pool.

Underground mine water quality is managed during Operations through mine dewatering and water treatment. Groundwater is pumped from the underground mine to the process plant and ultimately to the mine's water treatment plant (WTP) for treatment prior to discharge to the waste rock and tailings storage facility (WRTSF). The quality of underground mine water is expected to degrade during Operations due to the presence of potentially acid generating (PAG) mine wall exposures, waste rock and ore. As mining proceeds and PAG rock is exposed, the sulfides present in the rocks will oxidize over time, thereby generating acidity and potential metal leaching acid rock drainage (ML/ARD) issues. This acidity will initially be neutralized by carbonate minerals present in the rocks, but eventually the drainage is expected to acidify and metal concentrations in the mine are predicted to increase. The increase in metal concentrations in the underground mine will be managed through the WTP throughout Operations and into the Closure phase. The parameters treated by the WTP, along with the measured and modelled removal efficiencies are presented in Table 2-1.

The recommended long-term strategy for managing PAG rocks and the associated drainage is placement under permanent water cover such that oxidation reactions are essentially shut off (Price and Errington 1998). Flooding of the mine will ultimately result in effective management of ML/ARD since most of the mine wall exposures and all of the backfilled waste rock will be placed below the final water table elevation. However, as the mine is flooding, oxidation products that have built up on mine walls and backfilled waste surfaces will be flushed into the mine pool, resulting in elevated concentrations of several parameters of potential concern (POPCs). While most of the identified POPCs can be treated by the WTP, some cannot (i.e., nitrite, nitrate, Cr and Se). Managing the peaks in POPC concentrations and overall mine pool water quality during flooding will require an adaptive management approach.

Table 2-1. Measured and Modelled Water Treatment Removal Efficiencies for Parameters Treated by the Water Treatment Plant

Parameter	Units	% Removal Measured	% Removal Modelled
Ag	mg/L	0%	0%
Al	mg/L	98%	90%
As	mg/L	93%	90%
Cd	mg/L	32%	25%
Cu	mg/L	62%	50%
Mo	mg/L	27%	25%
Pb	mg/L	83%	75%
P	mg/L	82%	75%
Sb	mg/L	54%	50%
Se	mg/L	30%	25%
U	mg/L	65%	50%
V	mg/L	83%	75%
Zn	mg/L	32%	25%

Note: the %removal measured and %removal modelled are based on values presented in the 2020 Water Quality Model Review and Update (Lorax 2020a)

The options for management of the mine pool water quality during Closure include the following:

- Acceleration of the flooding rate by pumping WRTSF water into the underground mine. This would serve to both (i) dilute mine water concentrations, and (ii) reduce the exposure time of PAG rock, thereby limiting the time period over which oxidation products can be generated.

- Treatment of mine pool water with recirculation of the effluent to the underground mine at depth. This strategy would reduce the concentrations of treated parameters (Table 2-1).

- Treatment of mine pool water with discharge of WTP effluent to the WRTSF. This strategy would (i) minimize the potential for concentrations of untreated parameters to build up in the mine pool, (ii) afford additional dilution and buffering of loads within the WRTSF, and (iii) reduce the flooding rate, thereby reducing the monthly loads directed to the WTP.

A conceptual illustration of these potential management strategies is presented in Figure 2-1. The following section describes the proposed Base Case adaptive management strategy for managing water quality at Closure, along with adaptive management strategies that could be implemented should they be required.

Figure 2-1. Conceptual illustration of options for underground mine flooding and treatment at Closure.

2.2 BASE CASE MANAGEMENT STRATEGY

The Base Case Closure plan for managing water quality at Closure employs both accelerated flooding and water treatment strategies as described in Pretivm 2020c. The plan includes accelerated flooding of the underground mine by pumping or siphoning water from the WRTSF at the BJ 3.10 weir to the underground mine for a total of 7 months, at which point the mine pool reaches its final flooding elevation of approximately 1400 masl. The water would be pumped at a rate of 70 m^3/hr for a 4 month period, from January 2033 through to the end of April 2033. This rate represents the withdrawal rate specified in the mine's current water license. Starting in May 2033, water would be pumped to the underground mine at a higher rate, equivalent to 20% of the MMD (mean monthly discharge) at BJ 3.10 for an additional 3 months. This withdrawal rate is sufficiently low to minimize alteration to the flow regime of Brucejack Creek. No adverse effects on aquatic biota are anticipated due to the flows being within the normal high range of the creek.

In order to mitigate water quality through this accelerated flooding scenario, the water would be treated through the WTP at a rate of 10,000 m^3/day and recirculated to the underground mine. Water would be withdrawn using submersible pumps and returned to the mine pool at various locations. Water would be treated for a total of 15 months, covering the entire flooding period and an additional 8 months. This duration of treatment amounts to treatment of 4.5 Mm^3 of water, the equivalent of a volume 2.4 times the mine void.

The water quality results presented in the 2020 Water Quality Model Review and Update (Lorax 2020b) indicate that under this Base Case management scenario, water quality will be mitigated with no significant impacts to the receiving environment anticipated. Through the course of mining, as additional monitoring data is acquired (details are outlined in Section 2.4.1), the water quality

predictions and water management plans will be refined. This Base Case management strategy will be reviewed and updated, as necessary.

2.3 CONTINGENCY MANAGEMENT STRATEGIES

As flooding commences, various monitoring programs will be initiated (as described in Section 2.4.2), the results of which will inform decisions regarding whether contingency adaptive management strategies will need to be employed. Potential contingency management strategies in the event that water quality is substantively worse than expected include:

- deceleration of flooding rate;
- directing treated water to the WRTSF rather than recirculating to the underground; and
- extending the duration of active water treatment.

The following sections outline the potential contingency management strategies and conditions that would lead to their implementation.

2.3.1 Deceleration of Flooding rate

A contingency option to slow the filling rate would be implemented if the flushing loads released to the mine pool resulted in higher than anticipated concentrations of POPCs which could not be managed through the Base Case treatment and recirculation strategy described above. The water quality predictions for the mine pool chemistry at closure indicate that water treatment will be required in all cases; however, the duration of treatment will depend on the efficiency of treatment and recirculation. A reduced flooding rate would allow for a greater number of mine void volumes to be treated through the WTP (in the case of recirculation) before the mine pool water reached the threshold elevation of 1360 masl at which point contact water is anticipated to start flowing towards Brucejack Creek. Deceleration of the flooding rate could be achieved through various means including:

- Reducing the rate at which BJ 3.10 weir flows are pumped into the underground mine;
- Shutting down the BJ 3.10 weir pumps and allowing the mine to passively flood; and
- Directing the treated underground mine water to the WRTSF.

Decelerating the rate of flooding would allow for more intensive treatment of mine pool water and additional time for monitoring, but would also extend the exposure time of backfilled waste rock and mine walls, thereby exacerbating the effects of ML/ARD. Under this scenario, the treated water could be recycled to the underground mine or discharged to the WRTSF. The situation favouring discharge to the WRTSF is outlined in Section 2.3.2.

2.3.2 *Directing Treated Water to the WRTSF*

Another contingency option if the flushing loads released to the mine pool resulted in higher than anticipated concentrations of POPCs which could not be managed through the Base Case treatment and recirculation strategy described above would be directing treated mine water (or a portion thereof) to the WRTSF rather than recirculating it to the underground. This measure would result in several potential benefits to overall water quality including:

- Reducing the potential for concentrations of untreated parameters to build up in the mine pool as a consequence of recirculation.
- Afford additional dilution for mine pool loads and buffering of loads within the WRTSF. Predicted peak concentrations occur during the low flow months when groundwater discharge in Brucejack Creek experiences less dilution from surface runoff. These peaks could potentially be mitigated by directing the discharge into a larger reservoir (i.e., the WRTSF).
- Reduce the flooding rate, thereby reducing the monthly loads directed to the WTP (as described in Section 2.3.1).

The decision to direct WTP discharge to the WRTSF will be dictated by water quality of the mine pool and an assessment of the potential for parameter concentrations to go above specified water quality guidelines or discharge limits. The seasonal implications and the untreated parameter concentrations will determine whether WTP discharge (or a portion thereof) is directed to the WRTSF.

2.3.3 *Extending the Duration of Treatment*

Currently, based on modeling predictions, the Base Case Closure underground water quality management strategy entails a total treatment duration of 15 months to achieve mine pool water quality suitable for discharge either via subsurface pathways to Brucejack Creek or to the WRTSF. This treatment duration could be extended if necessary, to achieve suitable mine pool water quality. It is likely that treatment would be required throughout reflooding, or at least until the threshold elevation of 1360 masl when subsurface seepage would begin to follow towards Brucejack Creek. The benefit of treating water above this level for an extended time frame will be assessed through the monitoring programs developed for Closure (Section 2.4.2).

There is uncertainty in how long elevated concentrations could persist in the mine pool; current water quality modelling (Lorax 2020b) indicates that metal concentrations in Brucejack Creek will reach long term Post-closure levels within 3 to 5 years. Extending the duration of mine pool water treatment will minimize the time over which these levels are reached by reducing the flushing loads. The decision to extend active water treatment beyond 15 months will be based on water quality trends in the underground mine pool and Brucejack Creek during the Closure period.

2.4 MONITORING

2.4.1 Operations Monitoring

Monitoring data collected over the course of mine operations will be used to update the water quality predictions for closure and refine water quality management strategies. These data will be also be used to develop appropriate management triggers in due course. The sections below highlight the relevant monitoring programs that have been developed for Operations.

2.4.1.1 Underground Mine Water

Underground mine water data are routinely monitored and will continue to be monitored throughout Operations. These data are reviewed on a regular basis to verify water quality model predictions and ensure that water quality is being managed appropriately. Underground mine water data are critical for gaining insight into the anticipated mine pool water quality at Closure. Underground mine water sampling programs include the following:

- In-situ pH and conductivity measurements of underground seeps on a quarterly basis, with low pH samples analysed for the full suite of water quality parameters (pH, TSS, nutrients, anions and metals), as outlined in the ML/ARD Management Plan (Pretivm 2020b).
- Quarterly sampling of water from underground mine sumps, as outlined in Appendix 7 of the ML/ARD Management Plan.
- Sampling of drainage from backfilled stopes on a minimum of 2 stopes per year to assess soluble Cr loads released to mine water, as described in the Chromium Management Plan (Pretivm 2019).
- Monitoring of bulk underground water twice a month, as outlined in the ML/ARD Management Plan. These samples are used to verify the water quality model source terms and assumptions regarding the rate of onset of ML/ARD.
- Mine wall washing water quality samples carried out at lithology-specific stations on an annual basis. These data are used to evaluate flushing loads, as outlined in the ML/ARD Management Plan.

2.4.1.2 Underground Mine Rock, Paste Backfill and Precipitates

Ongoing characterization of rocks, paste backfill and mineral precipitates in the underground mine will provide critical information for refining Closure water quality predictions. These data will be used to determine estimates of flushing loads released upon submergence of backfilled paste, waste rock and wall rock during the Closure phase (*i.e.*, dissolution of soluble oxidation products). The relevant monitoring programs are described below:

- Confirmatory sampling of waste rock material will continue to be carried out throughout the Operations phase as described in the ML/ARD Management Plan; at least one composite sample for every 25,000 m^3.

- Confirmatory sampling of paste backfill samples will continue to be carried out on a quarterly basis to assess Cr concentrations, as outlined in the Chromium Management Plan.
- Kinetic test Programs have been developed and are being implemented for waste rock and paste backfill under both saturated and unsaturated conditions, as described in the 2020 ML/ARD Review and Update (Pretivm 2020b).
- Characterization of mineral precipitates in the underground workings will continue to be conducted, as part of the wall washing program described in the ML/ARD Management Plan.

2.4.1.3 Water Treatment Plant

The WTP influent and effluent data through the Operations phase will provide a good indication of how effective treatment will be in reducing loadings associated with underground mine water at Closure. The observed treatment efficiencies (Table 2-1) and overall WTP performance will be reviewed on a regular basis to ensure that the proposed management strategies are appropriate. WTP performance is currently assessed on an annual basis and presented in the annual reports. Ongoing WTP monitoring includes:

- WTP influent and WTP effluent samples collected twice a month and analyzed for the full suite of water quality parameters.
- WTP influent and effluent flows monitored continuously. As mine development proceeds, dewatering rates will increase. It will be critical to evaluate whether the WTP performance changes when treating at higher flow rates.

2.4.1.4 Groundwater

Groundwater monitoring comprises both groundwater quantity and groundwater quality monitoring. Both aspects of groundwater monitoring are ongoing and will continue through Operations. Groundwater quantity and groundwater quality monitoring are described in the Groundwater Monitoring and Sampling Protocol (Pretivm 2020a).

Continuous groundwater level measurements, in addition to underground flow rates, will be used to validate and/or update the groundwater model, which is used to predict the following:

- Inflows to the underground mine during future Operations;
- Flooding rates into the underground mine void at Closure;
- Time to flood the mine and the ultimate flooded elevation in the mine at Closure;
- The timing, volumetric flux and spatial distribution of contact water draining from the underground towards surface water receptors at Closure; and,
- Changes in baseflow at surface water receptors during Operations and Closure.

Continuous water level monitoring is achieved through dedicated water level loggers programmed to record water level pressure and temperature at 6 hour intervals. The datalogger records are cross-

referenced to manual water level elevations recorded at the time of sampling, typically two to four times per annum.

Groundwater quality sampling is specified on a quarterly or biannual basis as specified in PE-107835. The scope of groundwater quality monitoring may be modified on account of wells becoming dry through Operations. Groundwater quality monitoring is comprised of the following:

- In-line measurements of field parameters including temperature, pH, electrical conductivity, dissolved oxygen, oxidation-reduction potential and turbidity;
- Laboratory analysis of total and dissolved metals, physical parameters, anions, nutrients and sulphide.

The monitoring program will be used to determine changes in groundwater quality arising from the depression of water levels through operations. This may result in changes to the groundwater redox environment and concentrations of redox-sensitive parameters. This information will be used to confirm conceptualization of mine pool evolution at closure.

2.4.2 Closure Monitoring

Once flooding of the underground mine is initiated, it will be critical to ensure that the mine pool is responding as anticipated both in terms of flooding rate and water quality. Management triggers will be identified through the monitoring plans described above as additional data is collected. These triggers will identify water quality threshold limits and be evaluated on an ongoing basis. The sections below outline monitoring programs that will be carried out during Closure. It is likely that many of these programs will continue for some time into Post-closure.

2.4.2.1 Underground Mine Water

Monitoring of the underground mine water will continue during the Closure phase once flooding has commenced. Monitoring plans will include the following:

- Collection of monthly sump water quality samples from the accessible sump network.
- Installation of water level and conductivity loggers at different depths in the underground workings at closure via one or more air raises to measure water level rebound and electrical conductivity as a surrogate for mine pool water quality.
- Collection of monthly water quality samples from different depths in the mine pool via discrete sampling from one or more air raises.

2.4.2.2 Water Treatment Plant

The WTP influent and effluent data will continue to be monitored through the Closure phase to assess treatment efficacy and response to maximized WTP treatment flow rates (10,000 m^3/day). The WTP performance will assessed on an ongoing basis to determine whether adaptive management strategies will be required. The WTP monitoring will include:

- WTP influent and WTP effluent samples will continue to be collected twice a month and analyzed for the full suite of water quality parameters.
- WTP influent and effluent flows will continue to be monitored continuously.

2.4.2.3 Groundwater

Groundwater quantity and quality monitoring will continue into Closure. The monitoring program will include five additional monitoring wells slated for installation before or during Closure per PE-107835. Data collection from all monitoring wells slated for Closure monitoring includes the following:

- Continuous water level measurements via dedicated water level loggers programmed to record groundwater temperature and pressure;
- In-line measurements of field parameters including temperature, pH, electrical conductivity, dissolved oxygen, oxidation-reduction potential and turbidity;
- Laboratory analysis of total and dissolved metals, physical parameters, anions, nutrients and sulphide.

Continued water level monitoring through closure will be used to validate and/or update the groundwater model, facilitating prediction of the location and volumetric flux of contact water migrating from the underground to Brucejack Creek. The database of groundwater quality amassed though baseline, Operations and Closure will serve as an important benchmark for evaluating whether Closure groundwater quality is influenced by the flooded mine workings, thereby confirming contact water flow paths. Characterization of evolving groundwater redox conditions as the mine refloods will inform conceptualization of geochemical loadings to Brucejack Creek.

3 CONTINUOUS IMPROVEMENT, FOLLOW UP AND ADAPTIVE MANAGEMENT

The monitoring programs developed to evaluate closure water quality of the underground mine are currently part of existing management plans including:

- ML/ARD Management Plan (Pretivm 2020a)
- Chromium Management Plan (Pretivm 2019)
- Groundwater Monitoring and Sampling Protocol (Pretivm 2020a)
- Nitrogen Management Plan (Pretivm 2020d)

Field results collected through these existing plans are and will continue to be recorded when taken with external lab test results transferred electronically into a database.

Triggers and other performance indicators, corrective actions, and mine plans will be reviewed to identify potential operational improvements. Management strategies will be assessed and updated using evidence-based approaches, as necessary.

Mine pool information will be reviewed and incorporated into reports, as needed. These include at minimum:

1. Annual Reclamation Report required under Mines Act Permit M-243 for Construction and Operations; and
2. The updated Mine Plan and Reclamation Program for the mine, which must be submitted every five years to the Chief Inspector of Mines pursuant to *Mines Act* permit M-243. The Mine Plan and Reclamation Program update summarizes environmental data collected over the previous five years and documents validation of and any updates to the groundwater, water balance and water quality models.
3. The Closure Plan which must be submitted 12 months prior to final Closure pursuant to *Mines Act* permit M-243.

GLOSSARY

Term	Definition
Geohazard	Landslide, fluvial, glacial, or snow avalanche process with the potential to result in some type of undesirable outcome. For example, this could include a debris flow hazard area intersecting the footprint of a facility. The term geohazard refers to the specific nature of the process (type, frequency, magnitude), but not the consequences of a geohazard event. In this document, the term “geohazard” is used exclusively to describe naturally-occurring landslide, fluvial, and glacial hazards at the minesite. Snow avalanche hazards are not discussed in this plan.
Geohazard Event	Actual or potential occurrence of a geohazard resulting in an undesirable outcome. For example, this could include debris flow damage to a facility resulting in a one day loss of function. The term geohazard event refers to the specific nature of the consequences, but not their severity in terms of economic, environmental, safety, or reputation loss, or the likelihood this will occur.
Geohazard Risk	Likelihood of a geohazard event occurring and resulting in a particular severity of consequence, defined in terms of economic, environmental, safety, or reputation loss. For example, this could include the likelihood of debris flow damage to a facility resulting in $1M of economic loss.
Unsafe Situation	Situation of elevated geohazard risk. This would include site conditions indicating elevated likelihood of a geohazard event with the potential for consequences to workers or facilities (e.g., high rainfall while working in a stream susceptible to debris flows). Potentially unsafe situations not related to geohazards are not discussed in this report.

1.0 INTRODUCTION

The objective of the Geohazards Management Plan (GMP) is to make a safer workplace by providing workers with the tools to identify geohazards with the potential to cause damage and/or create unsafe working conditions. The GMP includes protocols designed to mitigate the potential adverse effects of geohazards.

Newcrest Mining Ltd. (Newcrest) retained BGC Engineering Inc. (BGC) to review and update the existing Geohazard Management Plan for the Brucejack Mine in northwest British Columbia, Canada. The Brucejack Gold Mine Project Geohazards Management Plan was finalized for Pretium Resources Inc. in 2014 and updated in 2016 following an annual geohazard inspection review (Pretium Resources Inc., November 26, 2014; Pretium Resources Inc., December 2016). The Pretium Resources Inc. GMP (December 2016) outlines the plan that was in place when Newcrest acquired the mine in March 2022.

This document provides an updated GMP for the geohazards identified by the terrain stability mapping completed for this updated plan (Drawings 01 to 05). Appendix A introduces landslide hazards in the context of the Brucejack project and provide on-site personnel with tools to:

1. Understand the factors affecting slope stability and triggering mechanisms leading to slope failure; and,
2. Recognize the main types of landslides, their characteristics, early warning signs and potential consequences.

Appendix B provides a summary of the updates made to the Pretium Resources Inc. (December 2016) version of the GMP. Appendix C provides a review of the use and performance of the existing GMP (Pretium Resources Inc., December 2016) as well as a review of geohazard events reported on site and weather data trends observed since 2014.

Based on previous work (BGC, July 31, 2015) and updated terrain mapping completed for this GMP update, the main geohazards at the Brucejack Minesite are landslides and snow avalanches. Considerations for ice fall and flooding are also discussed in the GMP update as they have been identified in the terrain mapping. The language and examples in the GMP update focus on landslides but the geohazard management strategies outlined in Section 5.0 (day to day actions, response protocol and periodic inspection) are applicable to landslides, ice fall, and flooding hazards. A management plan for snow avalanche hazards was provided by Alpine Avalanche Solutions (November 2014) and is not updated by this report.

2.0 PERFORMANCE OBJECTIVES AND SCOPE

The study area covered by this GMP is outlined in Drawings 01 to 05. This includes the existing road and building infrastructure present in the CAD drawing file, provided by Newcrest, “PVG 3300-DD30-SKT-0002.dwg” dated September 2, 2020. Drawings 01 to 05 show locations of geohazards in relation to these facilities, based on terrain mapping completed by BGC for this GMP update (Appendix B).

This GMP scope pertains to geohazards management for day-to-day operations. The performance objectives of this GMP and corresponding protocols provided by this GMP are for:

- Recognizing geohazard occurrence and unsafe situations
- Responding to geohazard event occurrence
- Minimizing worker exposure to geohazards
- Reporting and recording geohazard event occurrence.

The following is not considered by this GMP:

- Geohazards other than naturally-occurring landslide, glacial, and hydrotechnical processes
- Stability of anthropogenically modified terrain
- Infrastructure outside of the study area, including Bowser airstrip, Knipple Camp, Wildfire Camp, the transmission line, and the glacier access road
- Engineering design of any structural measures associated with facility design.

3.0 COMPLIANCE OBLIGATIONS, GUIDANCE, AND BEST MANAGEMENT PRACTICES

3.1 Relevant Legislation, Regulations, Permits and Environmental Assessment Conditions

- BC Mines Act (RSBC, 1996) regulates all mines during the exploration, construction, production, closure, reclamation, and abandonment phases.
- Health, Safety and Reclamation Code for Mines in British Columbia (the Code; BC Ministry of Energy, Mines, and Low Carbon Innovation [EMLI], 2022a), which is empowered under the Mines Act (RSBC, 1996). The purpose of the code is to:
    - Protect employees and all other persons from undue risks to their health and safety arising out of or in connection with activities at mines.
    - Safeguard the public from risks arising out of or in connection with activities at mines.
    - Protect and reclaim the land and watercourses affected by mining.
    - Monitor the extraction of mineral and coal resources and ensure maximum extraction with a minimum of environmental disturbance, taking into account sound engineering practice and prevailing economic conditions.
- British Columbia Guidelines for Reportable Incidents for Mines (EMLI, 2022b) is a supplement to the Code to assist with compliance of reportable incidents
- Permit M-243 is the Mines Act Permit for the Brucejack Gold Mine. Conditions specific geohazards assessment are contained in Section C.10 of the permit. The Geohazards Management Plan is also one of the management plans required and approved under M-243.

3.2 Guidance and Best Management Practices

Guidance and best management practice relevant to the GMP include:

- Guidelines for Legislated Landslide Assessments. Engineers and Geoscientists BC (EGBC, 2022)
- Mapping and Assessing Terrain Stability Guidebook (Ministry of Forests [MOF] and Ministry of Environment [MOE],1999)
- Terrain Classification System for British Columbia, Version 2 (Howes, & Kenk, 1997)
- Specifications and Guidelines for Terrain Mapping in British Columbia. (Resources Inventory Committee, 1996)
- Risk Management – Canadian Technical Guidelines and Best Practices Related to Landslides (VanDine, 2012).

4.0 DESCRIPTION OF GEOHAZARDS

This section provides overview description of geohazards within the project area. Appendix A introduces landslide hazards in the context of the Brucejack Mine to provide on-site personnel with tools to:

1. Understand the factors affecting slope stability and triggering mechanisms leading to slope failure; and,
2. Recognize the main types of landslides, their characteristics, early warning signs and potential consequences.

Protocols for date to-day actions and response to geohazard occurrences are provided in Section 5.0.

4.1 Summary of Geohazards

BGC identified landslide, glacial, and hydrotechnical geohazards in the mine site area of this GMP based on 2022 data sources provided by Newcrest (Appendix B). These geohazards are identified in terrain stability maps (Drawings 01 to 05) and include rockfall, debris flood, debris flow, debris avalanche, ice fall and flood hazards. These terrain maps form the basis for identifying potential naturally occurring hazards in relation to works sites. Risk posed to work sites by identified geohazards has not been assessed for this GMP update. Nonetheless, BGC considers all geohazards identified in Drawings 01 to 05 to be credible hazards.

The geohazards identified in the terrain stability maps include both geohazards that directly impact mine infrastructure (i.e., terrain polygons showing existing geohazard landforms that intersect mine infrastructure) and those distal to infrastructure with potential to reach mine infrastructure (i.e., where mine infrastructure is in the impact/runout zone of geohazards but away from the source). The potential impact areas of large scale distal geohazards are generally difficult to confine. Large scale hazards, such as ice falls, are generally less likely to occur in comparison to small scale hazards, such as rockfalls, however their potential effects are more severe.

5.0 GEOHAZARD PROTOCOLS

The GMP protocols are divided into three components:

1. Day to day actions.
2. Geohazard event responses.
3. Periodic inspections.

Day to day actions include:

- Watching for and communicating changes in the landscape and seeking expert review if unsure of the geohazard type observed, or its potential consequence
- Monitoring and forecasting weather conditions to define work and travel protocols with respect to weather conditions
- Recording precipitation and weather conditions for later correlation with geohazard events.

Geohazard events are defined as geohazard occurrences with the potential to result in an unsafe situation. Response includes:

- Actions when first recognizing and entering the area of a geohazard event
- Safe work procedures for working around geohazards
- Reporting, escalation levels and protocols: who to inform, and when.

Periodic review includes:

- Civil-geotechnical inspection of Newcrest facilities
- Procedures for geohazard risk review
- Adjustment of site protocols as appropriate.

5.1 Day to Day Actions

Day to day actions that Newcrest Operations Personnel (personnel) can undertake to minimize their exposure to geohazards include:

- Identifying landscape changes indicating geohazard occurrence or unsafe situations (Section 5.1.1)
- Determining the weather advisory level (Section 5.1.2)
- Following weather advisory work protocols (Section 5.1.3)
- Following appropriate geohazard event communication and response protocols (Section 5.2).

5.1.1 Identifying Landscape Changes

Visually identifying landscape changes that could indicate an increase in hazard is an important part of anticipating events that could result in injury (fatality) and/or damage to equipment. It forms part of the general site safety culture and encouraging site operations and construction teams to report landscape changes is important as they repeatedly see the same areas and can note subtle changes. An example of recognizing and reporting landscape changes can be notifying the shift supervisors of changing conditions, such as high water levels or the presence

of rocks on a road. Other example of landscape or facility condition changes that could be indicators of increased landslide hazard risk to facilities or workers include:

- Any changes in surface water drainage paths (e.g., stream avulsion) or landscape changes with the potential to lead to drainage path changes (e.g., landslides entering streams). Facilities are constructed to manage the surface drainage where it was encountered during construction and geohazard management approaches included avoidance (e.g., placing transmission poles away from creeks), and protection (e.g., construction of rip rap channels for cross drainage). If drainage paths crossing roads or transmission line change their path (avulse), facilities could be vulnerable to damage.
- Increasing frequency of small landslides may indicate an increased likelihood for larger and potentially more damaging events.
- Cut or natural slope failures, fill slope failures, or soil/gully erosion that could lead to undermining of facilities or increased vulnerability of facilities to up slope landslide hazards (e.g., structure foundations: pole, guys, and anchors).
- Slack or over-tensioned guy wires or conductors, or tilting or rotation or translation of transmission poles which could be associated with slope movement or soil creep or snow creep.
- New access road developments up slope of facilities as these can alter surface and groundwater flow patterns, potentially increasing the landslide susceptibility. Road fills on steep slopes may also create increased debris avalanche and debris flow potential.
- Changes in the landscape could alter surface and groundwater flow patterns, potentially increasing the susceptibility of terrain to landslides. In coordination with contractors, personnel will document changes to the landscape upslope and downslope of Newcrest facilities.

5.1.2 Weather Advisory Level

Weather conditions are an important trigger for many geohazards. To account for this, Newcrest has implemented protocols based on weather forecasts. Newcrest operates a climate station adjacent to the BJL-H1 hydrometric station (Lat 56 deg 28’ N, 130 deg 12’ W; elevation 1,360 m above sea level), near Brucejack Lake. Site avalanche technicians use meteorological data from site weather stations, contracted weather services, and Environment Canada to provide daily weather forecasts. These forecasts along with field observations are used to evaluate geohazard potential. The forecasts are disseminated by email each morning and discussed with crews during pre-shift safety meetings.

Based on experience estimating rainfall thresholds for other locations in British Columbia (Jakob & Weatherly 2003; Jakob et al., 2006; Jakob & Lambert, 2009), BGC currently recommends the use of 24-hour and 4-week antecedent rainfall values to derive a rainfall-initiated landslide hazard value. This process accounts for storm event rainfall (24-hour timeframe) and the accumulated rainfall of the previous several weeks (4-week antecedent accumulated rainfall). Table 5-1 provides a weather advisory matrix based on forecasted storm precipitation and 4-week antecedent precipitation. Additional factors exist that also influence

geohazard occurrence (freeze thaw cycles, temperature behaviour, freezing level, wind speed and short-term rainfall intensities). However, a more sophisticated advisory system may not be warranted for day-to-day operations given the limited data available for actual geohazard events and their timing in the local area. The weather advisory matrix should be read as follows:

1. Obtain the recorded rainfall in millimetres over the previous 4 weeks (4-week antecedent rainfall), and assign the appropriate category on the vertical axis.
2. Obtain the forecasted storm rainfall for the next storm cycle for rainfall events exceeding at least 6 hours of continuous rain above 1 mm/hr, and assign the appropriate category on the horizontal axis.
3. Follow the horizontal and vertical results into the middle of the matrix to obtain the advisory level.
4. During changing weather (precipitation) conditions, the advisory level should be frequently updated (e.g., several times per day).

The threshold values in the advisory should be reviewed and updated as more data on actual site precipitation versus geohazard site conditions or landslide events accumulate. Day to day operations will continue to maintain digital climate records so that they are available for correlation to geohazard events. Correlation of climate data and geohazard events can be used to refine hydro-climatic thresholds for Weather Advisory Levels.

Table 5-1 Weather advisory matrix.

4-wk Antecedent Rainfall (mm)	Storm Precipitation (mm) <25	25-50	50-75	75-100	>100
<150	L	M	M	H	VH
150-200	M	M	H	VH	VH
>200	M	H	VH	VH	VH

Notes:

1. If temperature at work site < 0°C lower rating by two categories unless already Low.
2. If temperature at work site >5°C and snow is on the ground (e.g., it is raining on the snowpack) raise rating by one category unless already Very High.

5.1.3 Weather Advisory Protocols

Table 5-2 presents weather advisory work protocols for areas subject to geohazards. On site identification of unsafe situations with respect to geohazards (see Section 5.1.1) should override the work protocols listed in this matrix.

Table 5-2 Weather advisory work protocols for areas subject to geohazards.

Weather Advisory Level	Hazard Zone Protocols			
	Road Traffic	**Vehicle Stoppage**	**Operational Works**	**Return to Work Guidance**
Low	No restrictions	No restrictions	Monitor for geohazards during repair or construction	N/A
Moderate	No restrictions	No non-essential vehicle stoppage	Consider delaying non-essential repair or construction work until weather conditions improve. Be prepared to suspend work if local weather conditions worsen.	Once the weather advisory returns to “low”
High	Advise road traffic of increased road hazard condition	No non-essential vehicle stoppage	Delay non-essential repair or construction work until weather conditions improve. Be prepared to suspend essential repairs if local weather conditions worsen. Evacuate workers from remote sites (e.g., sites inaccessible by road).	When safe, following the storm event, have Newcrest operations personnel complete a site inspection to identify any geohazard events. If a geohazard event is identified refer to Section 5.2 for geohazard response protocols.
Very High	Restrict road traffic to essential vehicle traffic only	No vehicle stoppage	Essential repairs only. Follow access and hazard/review monitoring protocols for sites with active geohazards.	When safe, following the storm event, have a qualified professional(s) supported by Newcrest operations personnel complete a geohazard review of Newcrest facilities. If a geohazard event is identified refer to Section 5.2 for geohazard response protocols.

5.2 Geohazard Response Protocol

Geohazard response refers to the sequence of actions following the occurrence of a geohazard event, or identification by workers of an unsafe situation with respect to geohazards. These actions include assessing the effect of the event on safety and operations, and determining how to safely access the area to restore normal operation, while not exposing personnel to intolerable risk.

5.2.1 Training

Response to a geohazard event or identified unsafe situation will be completed by personnel trained in:

- The non-geohazard related hazards of the facilities (e.g., power lines)
- Recognition of geohazard types with an understanding of their characteristics
- Risk evaluation protocols.

5.2.2 General Response Protocol

Evaluation of risk to personnel is required before investigating a geohazard event or situation, and/or repairing damage caused by a geohazard event.

Every geohazard event or situation response will be unique and requires its own evaluation and action plan. When personnel are in doubt about the appropriate response to a geohazard event or situation, the affected site area will first be closed off to all traffic and personnel. The Shift Supervisor will be contacted immediately (ideally with overview photos in an email and information to fill a Natural Hazard Incident Report form provided in Appendix D), any affected facilities will be prepared for shut-down, and a qualified registered engineer or geoscientist will be called in to support the hazard evaluation and response.

The general response protocol is:

1. Confirm no personnel were affected by the event. Account for all personnel.
2. Restrict entry within the affected area until the likelihood of further events is assessed. For events having an immediate effect on operations, inform the Mine Manager.
3. Assess the type, severity, and effects of the event. Assess the likelihood of further events that could affect safety at the site, with consideration of forecast weather and indicators of instability for the geohazard type. Limit access to essential personnel. Follow the best practices approach and assessment procedures summarized below when making assessments. If uncertain, obtain specialist advice.
4. Maintain communications and provide status updates to the Shift Supervisor and Mine Manager. If the situation warrants, inform any affected neighbouring operators or government officials with the potential to be affected by the event.
5. Describe site access and evacuation plan for any repair work. Consider elements such as a spotter, escape route, and weather monitoring.

6. When the site conditions are such that the risk to personnel is considered tolerable with the implementation of the proposed site access and evacuation plan, carry out clean up and repair work.
7. Collect photographs and document site observations within a natural hazard event report as soon as safely possible and practical. Use the Natural Hazard Incident Report form provided in Appendix D. In addition, the EMLI “Advice of Geotechnical Incident” form (Appendix D) will be completed by the Mine Manager and submitted to EMLI if applicable.

5.2.3 Geohazard Approach and Assessment Procedures

A geohazard event is more likely during or shortly after peak trigger conditions such as heavy rainfall, snowmelt, or a combination of both, and will generally occur in steeper terrain. It is often not clear if another event is possible, necessitating a high level of caution when approaching and assessing an event. The guidelines below will help minimize the exposure to personnel making an initial event assessment.

When responding to a geohazard event the following objectives should be met before close approach to the event:

1. Review the weather conditions and Weather Advisory Level and determine if precipitation intensity is increasing or decreasing. Avoid approaching the site until the rainfall threshold (Table 5-1) is moderate or lower.
2. Identify the type of geohazard (e.g., debris flow, rockfall, etc.) and its characteristics. When in doubt, workers should request the support of a qualified registered geoscientist or engineer.
3. Assess the limits of the area affected by the geohazard as much as possible without entering the affected area, so a safe zone can be established.
4. Establish a spotter well outside of the affected area with the ability to communicate with all personnel approaching the hazard area. The spotter must be able to visually appraise the event initiation area, and warn others if another event occurs. The spotter will be equipped with communication devices such as a very high frequency (VHF) radio or air horn, and warning system protocols established, in order to contact personnel in the hazard area. The spotter will sound a warning on the radio or sound one long blast of the air horn to notify personnel to evacuate the area immediately.
5. Assess the current activity of the geohazard. This should be done in stages, first visually and audibly (by sound) over a period of about 2 hours before entering the hazard area. Do not enter the area if there are any signs of ongoing activity (e.g., active landsliding or flooding).

Once steps one through five are complete, closer approach can be made for further assessment of the likelihood of additional events or movement. Most geohazards move down slope from an initiation point, so personnel should avoid the travel or runout zone of the geohazard when making further assessments. Head scarp areas should be approached from the side or above, not by climbing up the geohazard travel path. At all times ensure that a designated safe zone can be reached in two steps (i.e., two steps to safety). This stage of assessment should attempt

to identify additional imminent geohazards at or near the head scarp or source area, and establish more quantitative measurement of potential further movement (i.e., monitoring).

No individual will be permitted within the limits of the geohazard area until (at a minimum):

- A safety watch (spotter) has been established
- The trigger conditions for the event are no longer present (e.g., the rain has stopped and sufficient time has passed for the slope to drain)
- The limits of the geohazard (e.g., landslide) have been defined
- Ground movement within the affected area has stopped.

Under good light and working conditions this assessment may take a minimum of two hours to complete. If in any doubt about the adequacy of any of the requirements above, keep the area closed to personnel, and obtain specialist assistance.

5.2.4 Assessment Escalation

The Mine or Road Manager will determine escalation requirements for the response to and management of geohazard events. This could vary from no immediate action, to immediate specialist review. This decision will require judgment, based on factors such as:

- Weather conditions and Weather Advisory Level
- Type, size, and activity of the geohazard
- Potential for unsafe situations
- Potential or existing facility damage.

If in doubt, the Mine or Road Manager should retain a specialist to review the situation and support decision making.

5.3 Periodic Civil-Geotechnical Inspection of Facilities

On an annual basis, or following an exceptional weather event (e.g., 75% percent of a design weather event or following “Very High” weather advisory issuance), have a qualified professional(s) supported by Newcrest operations personnel complete a geohazard review of Newcrest facilities. Annual lidar change detection and/or satellite interferometric synthetic aperture radar (InSAR) are technologies that may be included as part of periodic civil-geotechnical inspections as they can record changes that took place over large areas, away from the main infrastructure, or that are too subtle to be observed visually.

Inspection Program Goals:

- Inspect for changes in site conditions that may increase the risk to facilities from geohazards and note areas of vulnerability for repair planning
- Increase understanding of local geohazard types and how they behave and could affect facilities
- Review and update geohazard areas described in Drawings 01 to 05
- Over time and based on site experience with weather events and geohazard initiation, review and update weather advisory level criterion described above.

Recommended Inspection Scope:

- Review of previous annual civil-geotechnical inspection reports.
- Office review of any specific areas of concern identified by operations and maintenance staff including, but not necessarily restricted to reported geohazard events. Reviews can include geohazard event documentation including photos or videos to assist in the evaluation of changing site conditions.
- Review of recorded mitigation measures applied to prevent or in response to geohazard events (i.e., scaling, ditch clearing, related construction activities, etc.). This includes follow up actions completed in response to prior geohazard review inspections, even if no follow up action was performed.
- Office review of on-site weather data, and evaluation of climatic events with respect to reported geohazard events and the effectiveness of established Weather Advisory Level criterion.
- Identify locations of changes in the landscape including: new developments such as access roads, borrow pits, forest cover changes, rights-of-way clearing and modifications or repairs to road networks, bridges, or culverts.
- Review and update baseline hazard mapping presented in Drawings 01 to 05 of the GMP.
- Low-level and high-level overflight inspections (helicopter or drone as appropriate) of the Newcrest facilities.
- Ground inspection of any specific areas of concerns noted by personnel or from helicopter flight inspections.
- Documentation of review with recommendations.

6.0 REPORTING AND RECORDING

6.1 Event and Mitigation Reporting

Operations personnel are encouraged to document geohazard events within the project corridor as soon as possible after they are observed. Areas of increased frequency of small landslides or rockfalls may indicate an increased likelihood for larger and potentially more damaging events. To standardize reporting, a Natural Hazard Incident Report Form is included in this document (Appendix D). The completed forms will be e-mailed to the Mine and Road Manager. Response to a geohazard event could vary from no immediate action recommended to immediate specialist review. When appropriate, the EMLI “Advice of Geotechnical Incident” form (Appendix D) will be completed by the Mine Manager and submitted to EMLI if applicable.

Mitigative measures taken (i.e., scaling, ditch clearing, related construction activities, etc.) in response to or in prevention of geohazard events should be documented and considered during annual geohazard inspections.

6.2 Record Keeping

Digital files of the event reports and photographs will be maintained on site and at Newcrest’s head office. Digital files will have a specific directory (e.g., Geohazard Events), and each event will have a separate sub-folder clearly labeled with the date, facility, location, and type of event. All associated event documentation will be stored in this folder with appropriate sub folders as necessary (e.g., Event Report, Photographs, Follow up Reports, etc.).

Digital files of event reports will have a consistent file name that allows them to be sorted chronologically, and that clearly identifies the event date, facility, location, and event type (e.g., 20230131 - Brucejack Access Road Km X – Debris Flood).

7.0 ADAPTIVE MANAGEMENT

The GMP is a “living” document that will evolve over time in response to monitoring results and changing site conditions and regulatory requirements. The GMP will be reviewed periodically to assess the effectiveness of mitigation and management measures (examples provided in Section 5.3) and whether plan objectives are being met.

8.0 CLOSURE

We trust the above satisfies your requirements. Should you have any questions or comments, please do not hesitate to contact us.

Yours sincerely,

THIS DRAWING MAY HAVE BEEN REDUCED OR ENLARGED. ALL FRACTIONAL SCALE NOTATIONS INDICATED ARE BASED ON ORIGINAL FORMAT DRAWINGS.

LEGEND

- MINE STUDY AREA
- EXISTING INFRASTRUCTURE
- WATERCOURSE
- TERRAIN POLYGON
- DEBRIS AVALANCHE OR SLUMP IN SURFICIAL MATERIAL (Rs, Rbs)
- ROCKFALL (Rb, R"b)
- ROCKFALL + DEBRIS FLOW, DEBRIS AVALANCHE, OR DEBRIS FALL (Rbd, Rds)
- FLOODING, FLUVIAL EROSION (U)

Simple Terrain Symbols: Used when one surficial material is present within a polygon

Example: Cb Rb

Surficial material — Geomorphological process sub-type
Surface expression — Geomorphological process (up to 3 may be assigned)

Composite Terrain Symbols: Used when 2 or 3 terrain types are present within a polygon

Cv.Mv	indicates that 'C' and 'M' are roughly equal in extent
Cv/Mv	indicates that 'C' is greater in extent than 'M' (about 60:40)
Cv//Mv	indicates that 'C' is much greater in extent than 'M' (about 80:20)

Stratigraphic Terrain Symbols

Cv|Mj	indicates that 'Cv' overlies 'Mj'
/Cv|Mj	indicates that 'Cv' partially overlies 'Mj'

Surficial Material Types

C	Colluvium	R	Bedrock	LG	Glaciolacustrine
L	Lacustrine	M	Glacial Till	FG	Glaciofluvial
F	Fluvial	O	Organic	I	Ice

Surface Expressions

p	Plain (0-3°)	v	Veneer (0-2 m thick deposit)
j	Gentle Slope (4-14°)	b	Blanket (>2 m thick deposit)
a	Moderate Slope (15-26°)	w	Variable Thickness deposit
k	Moderately Steep Slope (27-35°)	m	Rolling
s	Steep Slope (> 35°)	h	Hummocky
c	Cone (> 15°)	f	Fan (<15°)
r	Ridge	u	Undulating
t	Terrace		

Activity Level

FAp	'A' Indicates active floodplain (subject to channel changes)
Clf	'I' Indicates inactive fan

Geomorphological Processes

R	Rapid landslide (runout zone)	F"	Slow landslide (initiation zone)
R"	Rapid landslide (initiation zone)	F	Slow landslide (runout zone)
U	Flooding	L	Seepage
V	Gully erosion		

Geomorphological Process Subtypes (May be Combined)

b	Rockfall	u	Surficial material slump	a	Channel Avulson
d	Debris flows	r	Rock slides (Rr, R"r)	i	Ice fall
Ud	Debris floods	s	Debris avalanches	g	Rock creep

Examples

/Cv|Mb	Partial cover of a Colluvial Veneer over a till blanket
Rs//Cv - VR"bd	Steep bedrock with <20% cover of a colluvial veneer; gullied with initiation zones for rockfall and debris flows.

Drainage Classes

r	Rapid	w	Well	m	Moderate
i	Imperfect	p	Poor	vp	Very Poor

Surface Erosion Potential

VL	Very low potential - Flat or gently sloping terrain, organic soils, floodplain
L	Low potential - Gentle slopes, short slopes
M	Moderate Potential - Moderate steep slopes and long slopes, erodible (fine-textured) soils
H	High potential - Moderate steep slopes and highly erodible soil textures
VH	Very high potential - Steep slopes with erodible soil textures, active surface/gully erosion

Terrain Stability Class (Assigned to polygons intersecting proposed roads and fixed facilities)

I	No significant stability problems exist.
II	There is a very low likelihood of landslides following road construction. Minor slumping is expected along road cuts especially for 1 or 2 years following construction.
III	There is a low likelihood of landslides following road construction. Minor slumping is expected along road cuts especially for 1 or 2 years following construction.
IV	Expected to contain areas with a moderate likelihood of landslide initiation following road construction.
V	Expected to contain areas with a high likelihood of landslide initiation following road construction.

PROJECT: BRUCEJACK MINE GEOHAZARD MANAGEMENT PLAN – UPDATE

TITLE: TERRAIN MAPPING SOUTH

PROJECT No.: 1696001

DWG No: 05

X:\Projects\1696\001\Production\Report\20220110_Brucejack_Mine_Geohazard_Management_Plan_Update\DDP_Terrain_Mapping_10k.mxd Date: Saturday, October 21, 2023 Time: 5:37 PM

APPENDIX A
LANDSLIDE HAZARD CHARACTERISTICS

A-1 INTRODUCTION

This appendix introduces landslide hazards in the context of the Brucejack Minesite. The objective is to provide on-site personnel with tools to: 1) understand the factors affecting slope stability and triggering mechanisms leading to slope failure; and, 2) recognize the main types of landslides, their characteristics, early warning signs and potential consequences.

A-2 LANDSLIDE TERMINOLOGY

Landslides are defined as “the movement of a mass of rock, debris or earth down a slope” (Cruden 1991) and as “a physical system that develops in time through several stages” (Hungr et al., 2014). There are a number of other phrases/terms that are used interchangeably with the term “landslide” including mass movement, slope failure, and slope instability.

Landslide names are generated by determining an initiating material type for the landslide and a type of landslide movement. Common descriptors of landslide types are outlined below and summarized in Table A-1, with landslides relevant to the Brucejack Minesite in bold font. Landslides are further described by their rate of movement summarized in Table A-2.

Material type terms:

- Rock – pre-failure intact bedrock
- Soil – including clay, mud, silt, sand, gravel, boulders, debris and peat.

Movement type terms:

- Fall
- Topple
- Slide
- Spread
- Flow
- Slope deformation.

Table A-1 Landslide type classification (after Hungr et al., 2014).

Type of Movement	Rock	Soil
Fall	**1. Rock fall***	*2. Boulder/debris/silt* fall*
Topple	3. Rock block topple*	*5. Gravel/sand/silt* topple*
	4. Rock flexural topple	
Slide	6. Rock rotational slide	***11. Clay/silt* rotational slide (surficial material slump)**
	7. Rock planar slide*	*12. Clay/silt* planar slide
	8. Rock wedge slide*	*13. Gravel/sand/debris* slide*
	9. Rock compound slide	*14. Clay/silt* compound slide
	10. Rock irregular slide*	
Spread	15. Rock slope spread	*16. Sand/silt* liquefaction spread*
		17. Sensitive clay spread*
Flow	18. Rock avalanche*	*19. Sand/silt/debris* dry flow
		20. Sand/silt/debris flowslide*
		21. Sensitive clay flow slide*
		22. Debris flow*
		23. Mud flow*
		24. Debris flood*
		25. Debris avalanche*
		26. Earthflow*
		27. Peat flow
Slope Deformation	28. Mountain slope deformation	30. Soil slope deformation
	29. Rock slope deformation	31. Soil creep
		32. Solifluction

Notes:

1. For material types in italics, use one only.
2. *Denotes movement types that usually reach extremely rapid velocities as defined by Hungr et al. (2014). The other landslide types are most often (but not always) extremely slow to very rapid.

Table A-2 Landslide velocity classification (after Hungr et al., 2014).

Description	Velocity (mm/s)	Typical Velocity
Extremely Rapid	$5X10^{3}$	5 m/s
Very Rapid	$5X10^{1}$	3 m/min
Rapid	$5X10^{-1}$	1.8 m/hr
Moderate	$5X10^{-3}$	13 m/month
Slow	$5X10^{-5}$	1.6 m/year
Very Slow	$5X10^{-7}$	16 mm/year
Extremely Slow	-	-

A-3 FACTORS AFFECTING SLOPE STABILITY

Slope failures are the result of gravitational forces acting on a mass which result in slow creep, free fall, sliding along a failure surface, or flow as a slurry, with stability and behavior of the failure dependent on different variables, including:

- Site topography and downslope materials
- Bedrock stratigraphy
- Material properties (including material structure and strength)
- Groundwater conditions
- Vegetation type and cover
- Anthropogenic modifications
- Seismic activity.

Two forces affecting the stability of slopes include: 1) Gravitational forces (shear stress) that causes the slope to move (force pulling it down); 2) Resisting forces (shear strength) that stabilize the slope and prevent movement (force holding it up). When gravitational forces exceed the resisting forces, a slope instability occurs. A simplified diagram of the forces affecting slope stability is shown in Figure A-1.

Figure A-1 Diagram of simplified forces acting on a slope (modified from BCMOF, 1994).

Slopes can be sensitive to modifying factors which change the shear stress and or shear strength over time and therefore affect the likelihood that slope instability can be triggered. Some changes in material and mass properties are gradual effects occurring over time whereas some changes are almost immediate such as those from climatic events.

Decrease in Shear Strength

Several different processes can lead to reduction in the shear strength of slope materials. The processes most relevant to the Brucejack Minesite include:

1. *Development of a high or perched water table* (increased soil pore water pressure). Increased soil pore water pressure reduces shear strength in soil, between soil or rock surfaces, and in joints (cracks) in rock. If subsurface groundwater flows are less than infiltrating rates for extended periods of time, a perched or high groundwater table will form within overburden soils. Rising groundwater levels and the effects of adverse seepage can commonly develop during periods of intense rainfall, rapid snowmelt, or prolonged high precipitation. Increases in groundwater levels can also be caused by leaking pipes or penstocks, and drainage redirection associated with road networks that concentrate surface water flows. All types of soils can be affected by the development of high water tables, with the length of time required for pore pressures to change dependent upon the permeability of soil.
2. *Removal of vegetation cover.* Tree cover influences the amount and intensity of rainfall reaching the ground surface as well as the amount of water stored in the ground. Root systems of trees and other vegetation also increase the strength of overburden soil by roots providing long-fiber binders within the overburden soil. When tree cover is removed (as a result of timber harvesting, forest fires, or wind throw) there can be a corresponding change in the soil water retention and runoff, and a decrease in soil shear strength as roots decay.

3. *Weathering.* Weathering is a common process that alters rock to soil over time and affects particles in soil as well as bedrock. Weathering involves various physical, chemical, and biological processes.
4. *Cyclic loading.* Under the influence of cyclic loads, such as those caused by earthquake shaking, bonds between soil particles may be broken and pore pressures may increase. Loose sands can liquefy under cyclic loading, lose virtually all strength, and flow like a liquid.

Increase in Shear Stress

Even if the strength of the soil /rock mass does not change, slopes can fail if the loads on them change, resulting in increased shear stresses within the soil. Mechanisms through which shear stresses can increase include:

1. *Overloading of slope.* If the ground at the top of the slope is loaded, the shear stress will increase. Common occurrences that provide surcharge loading of the ground are the placement of fill and construction of buildings supported on shallow foundations.
2. *Water pressure in cracks at the top of the slope.* If tension cracks at the top of a slope are filled with water (or partially filled), the water pressure in the cracks loads the soil within the slope.
3. *Water freezing in cracks.* The expansion of water as it freezes within cracks imposes an outward lateral stress within the slope. Freeze-thaw actions can act to jack apart existing fractures in rock.
4. *Increase in soil weight due to increased water content.* Infiltration and seepage into the soil within a slope can increase the soil water content thereby increasing its weight.
5. *Removal of support.* Excavations or erosion that make a slope steeper or higher will increase the shear stresses in the slope and reduce stability.
6. *Earthquake shaking.* Earthquakes subject slopes to horizontal and vertical accelerations that result in cyclic variations in stresses within the slope increasing stress beyond the static condition for brief periods.

A-4 TRIGGERING MECHANISMS

Landslides can have several causes (factors) that may reduce the stability of a slope and lead to failure in a progressive fashion (progressive failure). These include geological, morphological, physical, and human causes as outlined in Table A-3. However, the final impetus leading to slope failure may not be a gradual degradation of the landslide failure surface (progressive failure) but instead some external stimuli ‘triggering’ a slope failure. Examples of external stimuli, or triggering mechanisms, include intense rainfall, earthquake shaking, or human slope modification that results in failure by rapidly changing either shear stresses, or shear strength. Note that some triggering mechanisms can also be considered as causative factors in some cases. For example, an earthquake may not trigger a landslide, but weaken slope material, making the slope more susceptible to failure over time.

Table A-3 Factors that may reduce the stability of a slope (after Cruden and Varnes, 1996).

1. Geological causes	a. Weak materials b. Weathered materials c. Jointed or fissured materials d. Adversely orientated discontinuity (bedding, rock joints, etc.) e. Contrast in permeability
2. Morphological causes	a. Glacial debuttressing b. Fluvial erosion of slope toe c. Subterranean erosion (solution, piping) d. Landslide deposition loading of slope or its crest e. Vegetation removal (forest fire, disease, wind storm, drought)
3. Physical causes	a. Intense rainfall* b. Rapid snowmelt* c. Prolonged exceptional precipitation* d. Earthquake* e. Freeze–and-thaw actions / weathering* f. Change in groundwater level*
4. Human causes	a. Excavation of slope or its toe* b. Loading of slope or its crest c. Deforestation d. Irrigation or water leakage from utilities* e. Surface water re-direction* f. Artificial vibration*

In many cases landslides occur as progressive failures absent of a triggering mechanism. For this reason, an awareness of geohazard processes is essential if causative factors that may lead to landslide events exist. In several other cases however, a triggering mechanism can be attributed to the landslide event. Therefore, common triggering mechanisms are described below.

Intense or Prolonged Rainfall

Storms that produce intense rainfall for periods as short as several hours or have a moderate intensity lasting several days are known to act as triggers for landslides. The rapid infiltration of rainfall causing soil saturation and a temporary rise in pore-water pressures reduces available shear strength, triggering failure. Alternatively, prolonged precipitation with moderate intensity can also result in soil saturation and temporary rise in pore-water pressures.

Intense rainfall or prolonged moderate precipitation can occur at any time in northeastern BC, however, the most consistent period of intense or prolonged rainfall events occurs over the fall season.

Rapid Snowmelt

Rapid melting of a snowpack caused by a sudden warming spells or by rain falling on snow can have the same effect as intense precipitation. Snowmelt, leading to high surface and subsurface water flows, generally occurs during the spring and early summer seasons. Rain on snow events occur when a warm Pacific frontal storm system dramatically raises the freezing level combined with high precipitation. This causes rapid snowmelt to add to already high precipitation. These events usually occur between late fall and early spring.

Freezing-Thawing

The expansion of water as it freezes in rock joints or fissures can promote rock wedging and reduce rock joint strength. Freezing of surface water on slopes can also block drainage paths (seepage outlets) resulting in a build-up of water pressure in the slope which can result in reduced shear strengths. The active freeze-thaw cycle is most prevalent in the spring season and the fall season when daily temperatures rise above and fall below 0°C allowing hydrostatic pore pressures to develop within a rock fractures and then similarly allowing ice to form and expand within fractures.

Earlier Landslide Events

For some situations a smaller landslide event can act to change ground conditions and make a second landslide event more likely. For example, landsliding could result in the removal of slope support, such as in the case of an over steepened head scarp following a rock fall event. The accumulation of landslide debris along a slope or within a confined channel can also act as a surcharge load or disrupt slope drainage contributing to continued slope instability.

Earthquake Shaking

Strong ground shaking during earthquakes has triggered landslides in many different topographic and geologic settings. Rock falls, debris avalanches, and rock avalanches from steep slopes involving relative thin or shallow disaggregated soils or rock are the most common failure types. Earth and debris slides on gentler slopes are also very abundant during earthquakes.

A-5 LANDSLIDE TYPES

A-5.1 Rock Falls, Rock Slides and Rock Avalanches

Rock fall is a fragment of rock or boulder that detaches from a steep slope by sliding or toppling (Figure A-2). The rock or boulder may free-fall and break upon impact, or may begin rolling or bouncing down steeper slopes before arresting on flatter terrain. Rock falls are usually of limited volume (i.e., less than 10,000 m3).

Rock avalanches are extremely rapid, flow-like motion of disintegration of the rock mass that initiated as large rock slides or rock falls.

Characteristics of rock falls, rock slides and rock avalanches include:

- Abrupt and extremely rapid landslide events (velocities of rock avalanches have been noted to be in excess of 200 km/hour)
- Their runout path is influenced by topography, which can deflect their trajectory
- With increasing rock mass involved in a failure, movement changes from falling and bounding to a more flowing movement; this transition from rock fall to rockslide to rock avalanche is fluid and it is sometime difficult to distinguish
- Failures can run out past the toe of steep slopes. The run out distance depends on the fall height and the volume involved. Rock avalanches greater than about 1 Mm3 in volume can have a high mobility and long run-out distances.

Figure A-2 Rock fall, rock slide, and rock avalanche schematic (from Louisiana State University website).

Rock Fall, Rock Slide and Rock Avalanche Event Causes

Causal factors:

- Steep and sub-vertical rock slopes as source zones
- Bedrock discontinuities such as fractures, joints, fault and bedding planes that intersect with the slope configuration to form block geometries that can slide down and out of the slope or topple out of the slope
- Erosion at the base of slopes from rising rivers and streams or from human related disturbances such as undercutting
- Likelihood is strongly influenced by mechanical weathering (tree roots or ice formation prying rock).

Trigger conditions:

- Rainfall or snowmelt events increasing water pressure in fissures

- Freeze-thaw cycles causing mechanical weathering of the rock mass
- Seismic events.

Early Warning Signs

Indicators of imminent rock fall can include terrain with overhanging rock or rock with open joints (fissures) or blocks that are separating from the surrounding rock. Fresh rock fall evidence includes recent rock fall impact marks, rock fragments in ditches, fresh rock faces at the source area, and torn soil layers at the slope crest.

Larger rock avalanches often show signs of instability before failure including:

- Slope deformation and slope cracks
- Vegetation disturbance
- Slow measurable movements
- Repeated small rockslides and rock falls.

Consequences

Structures and access roads within the run-out path of a rock fall or rock slide can also be severely impacted by the momentum of the blocks or debris. Structures and access roads within the run out path of a rock avalanche will be destroyed and buried by the mass of debris.

Possible safety concerns include direct impact from rock fall, rock slide or rock avalanche, or running into blocks and debris while travelling on an access road affected by an event.

Secondary effects may generate consequences away from location of large rock slide and rock avalanche events. For example, the debris of large rock slides and rock avalanches may temporarily dam a stream, which may cause flooding upstream of the dam, or outbreak floods downstream if the dam breaches. Large rock slides and rock avalanches impacting a lake may generate displacement waves.

A-5.2 Debris Avalanches

Debris avalanche is an open-slope slide formed when an unstable slope collapses and the resulting fragmented debris rapidly moves down the slope (Figure A-3). Debris avalanches initiate as debris slides and occur on open slopes without confinement of an established channel.

Characteristics of debris avalanches include:

- Very rapid to extremely rapid shallow landslides with event velocities that range from 3 m/min to in excess of 80 km/hour
- Generally, originate from steep hillslopes or from within shallow hillslope depressions (hollow) where groundwater is concentrated
- Fragmented debris travels downslope, in some instances extending over 1 km downslope from the source zone
- Landslide dimensions range from head scarps spanning only a few meters in width to head scarps with widths greater than hundreds of meters.

Figure A-3 Debris avalanche schematic (Highland and Bobrowsky, 2008).

Debris Avalanche Event Causes

Causal factors:

- Steep slopes
- Weak surficial material (overburden) over higher strength lower permeability material such as bedrock or glacial till
- The occurrence of debris avalanches can be intensified on slopes or in gullies that have been denuded of vegetation due to forest fires or timber harvesting.

Trigger conditions:

- Intense rainfall, prolonged intense rainfall, rapid snowmelt, or rain on snow events
- Surface water concentration associated with poorly constructed or poorly maintained access roads
- Seismic events.

Early Warning Signs

If a debris avalanche event is triggered, the resulting slide could form rapidly with little warning. Early warning for the event can be any signs of land movement such as tension cracks, smaller landslides or progressively tilting trees. Small changes can indicate an increased immediate threat of a slide. Sounds that might indicate moving debris include trees cracking or boulders knocking together; a trickle of flowing or falling mud or debris may precede a larger landslide.

Consequences

Structures and access roads on the slide can be severely damaged or destroyed. Structures within the run-out path can also be severely impacted by the momentum of the mass of material. If a debris avalanche or debris slide deposits material within a confined creek channel, a debris flow or sediment laden creek flood can be initiated.

Possible safety concerns include direct impact from landslide debris or running into debris while travelling on an access road affected by an event.

A-5.3 Debris Flows

Debris flow is a very rapid to extremely rapid surging flow of saturated debris in a steep channel (Figure A-4). Debris flows exhibit strong entrainment of material and water from the flow path (Hungr et. al., 2014). Debris flows are sometimes informally called “mudslides”. Debris flows are part of a spectrum of channel processes that range in order of increasing sediment concentrations from clear water floods to debris floods to debris flows (Figure A-5). Debris flows are typically triggered by side slope landslides or progressive bulking with erodible sediment. Dilution of a debris flow through partial sediment deposition on lower gradients channels and tributary injection of water can lead to a transition towards debris floods and eventually floods.

Characteristics of debris flows include:

- Very rapid to extremely rapid flow movements with event velocities ranging from 3 m/min up to 80 km/hour. The velocity of flows depends upon channel gradient, water content, material mobility, and evolution of the movement.
- Initiation within steep confined channels during high runoff periods (rainfall or snowmelt) being triggered by high stream flow mobilizing in-stream material and eroding and entraining additional channel material as the debris mass flows down the channel.
- Coarser material collecting at the front and sides of the flow. It is common to see boulders “floating” and tumbling at the front of the debris flow.
- Super-elevation of the flow around bends causing debris to deposit at a higher elevation on the outside of the bend.
- Creation of debris levees (raised ridges) at the margins of the flow.
- Deposition of material where the slope gradient flattens. This commonly occurs where channels transition to a colluvial fan or cone.
- Transport and deposition in “surges” or “lobes”. It is common for subsequent surges to divert out of the channel (avulse) when they come up against channel blockage caused by deposition of the preceding surge.
- More fluid discharge with finer sediment in later surges of a flow. This later stage often cuts down through previous deposited lobes, further re-mobilizing sediment.

Figure A-4 Debris flow schematic (https://domino.dei.unipd.it/features/debris-flows/).

Debris Flow Event Causes

Causal factors:

- Steep channel gradients (typically greater than 10° to 15°)
- Source of sediment – either in channel bedload or channel sidewalls or from other landslides that deposit in the channel
- Changes to the hillside surface and groundwater flow patterns caused by loss of tree cover from forest fires or timber harvesting, or from roads and trails that collect and direct surface water drainage.

Trigger conditions:

- Intense surface-water flow due to heavy or prolonged precipitation or rapid snowmelt that saturates, erodes, and mobilizes loose soil or rock on steep slopes
- During high stream flow, the initiation of smaller debris slides from gully channel side walls that then imped creek flow leading to a super-saturated plug of debris mobilizing into a debris flow in the channel.

Early Warning Signs

At a stream level observation point, an early warning sign of the potential for an imminent debris flow event is the rapid increase of sediment content and sediment pulses through the stream channel; the sediment content increase and sediment pulses may be the remnants of smaller debris flows upstream of the observation point indicating that triggering conditions for larger debris flows are imminent.

Consequences

Debris flows may be life-threatening as they can be extremely rapid and may occur without any warning. The erosive potential of the debris laden sediment flows is such that it can entrain

large boulder and rapidly transport them downstream. Debris flows can move objects as large as houses or can fill structures with a rapid accumulation of sediment and organic matter. Structures, including bridges and culverts, may be overwhelmed and destroyed by the momentum of the mass of material. Subsequent erosion from creek flow that has changed its path after the event can erode and undermine structures.

At the break of slopes, where channels become unconfined, flows can easily avulse and deposit silt and debris on a fan feature with high impact forces. In some instances, where a flow enters another river or stream, debris floods can be generated that further impact bridge structures located downstream. Debris flows can affect the quality of water by depositing large amounts of silt and debris.

Safety concerns include direct impact from landslide debris, running into debris while travelling on an access road affected by an event, or road washout limiting road passage.

Figure A-5 Hydrogeomorphic process classification by sediment concentration, slope velocity, and planform appearance.

APPENDIX B
SUMMARY OF GEOHAZARD MANAGEMENT PLAN UPDATES

B-1 INTRODUCTION

For convenience and record keeping, this appendix provides a summary of the updates to the GMP from the 2016 version (Pretium Resources Inc., 2016). It also includes details on the terrain mapping methodology. Terrain mapping over the minesite area was updated using 2022 lidar digital elevation model and orthophotos as part of the current scope.

B-2 SUMMARY OF GEOHAZARD MANAGEMENT PLAN UPDATES

In general, the 2016 GMP was updated by removing references to infrastructure supporting construction activities that are no longer in use (e.g., Bowser Camp).

Section 3.1 pertaining to the relevant legislation, regulations, permits and EA conditions was updated to reference the up-to-date versions of the relevant documents. It includes the recently published guidance by the BC Ministry of Mines, Energy and Low Carbon Initiatives on reportable incidents.

Section 3.2 on landslide guidance documents and best management practices was added to provide additional framework for the GMP.

Section 4.0 was updated to address the geohazards identified in the update terrain stability maps.

Section 5.3 was updated to acknowledge the increased use of drones to do inspections. It also identifies that lidar change detection and satellite InSAR can contribute to periodic civil-geotechnical inspections.

Section 6.1 was expanded to also include mitigation reporting. This is to better capture the efforts to manage geohazards at the Brucejack Minesite.

Section 7.0 Adaptive Management was added to further emphasize that the GMP should be updated as needed to incorporate up-to-date information regarding geohazard rating, activity and infrastructure layout.

Appendix A – Landslide Hazard Characteristics was included in the GMP to provide on site personnel with reference material to allow them to understand the contributing and triggering factors of slope instabilities and to recognize the main types of landslides, characteristics, and potential consequences.

Appendix C – Preceding Geohazard Management Plan Performance and Recommendations was included in the GMP synthesize past annual reviews and meteorological data which was then used to support recommendations in the implementation of this updated GMP.

Appendix D – Geohazard Reporting Forms Updated and was included in the GMP to present the new simplified event geohazard reporting form for internal purposes and it also includes a copy of the latest “Reportable Incident” form for the BC Ministry of Mines, Energy and Low Carbon Initiatives.

B-3 ADDITIONAL DETAILS ON TERRAIN MAPPING METHODOLOGY

BGC previously completed terrain stability mapping for the Brucejack Mine project area in 2014 with revisions made in 2015 (BGC, June 5, 2014; BGC, July 31, 2015). Updates to this terrain stability mapping were made in 2023 for the study area outlined in the main body of this report based on updated data provided to BGC by Newcrest. A summary of the data sources used to complete these updates and a summary of the methods used are presented in this Appendix.

B-3.1 Data Sources

The data sources used to update terrain mapping and identify credible geohazards in study area include:

- A mine site layout (.dwg file) dated September 2, 2022 and provided by Newcrest on November 8, 2022
- Lidar-based digital elevation data and ortho imagery (August 8, 2022) covering the mine facilities and area surrounding Brucejack Lake was provided by Newcrest on November 8, 2022
- Terrain stability mapping generated by BGC in 2014 and updated in 2015 (BGC, July 31, 2015).

B-3.2 Terrain Stability Mapping Methods

Criteria that were used to map these characteristics are described below. Mapping methods were based on guidelines described by the Resource Inventory Committee (1996), using the terrain classification of Howes & Kenk (1997).

Symbols describing material types and drainage classes were added to all terrain polygons. All polygons intersecting the proposed general arrangement of roads and fixed facilities were also assigned terrain stability classes. Material types and stability classes are shown on Drawings 01 to 05.

B-3.3 Mapping Reliability

The minimum size of terrain polygons that can be mapped at 1:20,000 scale terrain mapping is about 2 ha. Thus, local variations in terrain conditions over areas of 2-3 ha, or over distances of less than about 150 m, may not be identified. As a result, within any polygon, variations in slope steepness, material characteristics and soil moisture should be expected. Consequently, small features may not be reflected in the assessment. Terrain stability ratings reflect average conditions in the polygon. Facilities that intersect only a small part of a terrain polygon may have slope stability conditions that are different from the average rating.

B-3.4 Surficial Materials

In general, surficial materials can be considered to be of relatively young geological age. Other terms that are often used for surficial material are Quaternary sediments, unconsolidated materials, earth, and soil. Surficial materials are classified according to their mode of formation.

Specific processes of erosion, transportation, deposition, mass wasting and weathering produce materials that have specific sets of physical characteristics (Howes & Kenk, 1997). Typical descriptions of each material mapped within the Brucejack Minesite area, with their mapping codes, are given in the following sections.

Glaciofluvial (FG)

Glaciofluvial material is typically composed of coarse sands and gravels, deposited during the immediate post-glacial and earlier interglacial periods. It is commonly located in terraces above present river level.

Fluvial (F, FAp)

Fluvial material is deposited by the current river either in floodplains or low terraces and is typically composed of sand and gravel. Areas mapped as active floodplains (FAp) have little vegetation and are regularly flooded.

Colluvium (C)

Colluvium is material that has weathered and eroded from bedrock or other deposits and has been moved downslope by gravity. It is common as a thin veneer (< 1 m thick) on rocky slopes and as thicker deposits at the base of slopes which have experienced slumping or land sliding. The texture of colluvium reflects its source - where derived from bedrock, colluvium will typically be silt to gravel sized with some boulders and highly disturbed bedrock.

Till (M)

Till is material that has been deposited by glacial ice. Typically, it is a highly consolidated deposit consisting of poorly sorted, usually matrix-supported subangular or subrounded clasts in a clayey sandy-silt matrix. It is common as thick blankets or thin veneers throughout the study area.

Organic (O)

Organic material is sediment that is composed largely of partially decomposed vegetative matter. It is common on floodplains of along major streams.

Bedrock (R)

Bedrock material is solid consolidated rock. Applies to bedrock outcrops and rock covered by up to 10 cm of unconsolidated organic materials.

Ice (I)

Ice material is considered ice and snow involved in active glacier movement. Applies to all glaciers and associated permanent snowfields.

B-3.5 Drainage Classes

Drainage classes rate the potential for water to drain from a given polygon in relation to water supply (Table B-1). These drainage classes provide information that can influence road construction and design of drainage and erosion control structures. Drainage classes were assigned to all polygons but are not shown on the drawings.

Table B-1 Example materials and locations for each drainage class (RIC 1996).

Drainage Class	Description	Example Materials and Locations
Rapid (r)	Water is removed rapidly in relation to supply	Exposed rock
Well (w)	Water is removed from the soil readily but not rapidly	Sand and coarser grained sediments, typically on upper slopes
Moderate (m)	Water is removed from the soil somewhat slowly in relation to supply	Sand and coarser grained sediments, typically on mid-lower slopes
Imperfect (i)	Water is removed from the soil sufficiently slowly in relation to supply to keep the soil wet for a significant part of the growing season	Coarser to finer grained sediments on lowermost slopes, gully bottoms, and in moist areas of floodplains
Poor (p) Very Poor (vp)	Water is removed so slowly in relation to supply that the soil remains wet for a comparatively large part of the time the soil is not frozen	Bogs in bedrock depressions, marshy or wet areas of floodplains

B-3.6 Terrain Stability Interpretations

Terrain stability refers to the potential for landslide initiation within the polygon following disturbance by road construction or removal of forest cover. Terrain stability ratings range from Class I (stable) to Class V (unstable), as shown in Table B-2 and were added to all terrain polygons intersecting proposed facilities. The classes are based primarily on slope steepness, surficial material type, and geomorphological processes occurring within the polygon (e.g., gully erosion or existing landslides) as shown in Table B-3. For example, a slope morphology that includes irregular, near-surface bedrock would typically be rated as more stable than a similar slope with a smooth profile, because bedrock irregularities tend to stabilize soil against failure. Polygons with existing landslides in bedrock or surficial material are automatically assigned Class V ratings. Existing landslides are included in the assessment of terrain stability.

As terrain stability ratings consider terrain disturbance in the stability class, they are not directly equivalent to estimates of hazard likelihood. They are primarily used to identify areas requiring more detailed stability assessment prior to logging, road construction, or other construction. Terrain Stability Field Assessments (TSFA's) are usually carried out prior to forest clearing or road construction on terrain mapped as terrain stability classes IV and V and should also be referenced where existing.

Table B-2 Terrain stability rating for road construction.

Terrain Stability Class	Interpretation
I	No significant stability problems exist.
II	There is a very low likelihood of landslides following road construction. Minor slumping is expected along road cuts, especially for 1 or 2 years following construction.
III	There is a low likelihood of landslide initiation following road construction. Minor slumping is expected along road cuts, especially for 1 or 2 years following construction.
IV	Expected to contain areas with a moderate likelihood of landslide initiation following road construction.
V	Expected to contain areas with a high likelihood of landslide initiation following road construction.

Table B-3 Criteria used to assign terrain stability classes (modified from Ryder, 2002).

		SLOPE CLASS					
		Plain (p) 0-5% (0-3°)	Gentle Slope (j) 6-27% (3-15°)	Moderate (a) 28-49% (15-26°)	Moderately Steep (k) 50-60% (26-30°)	Moderately Steep (k) 61-70% (31-35°)	Steep (s) >70% (>35°)
TERRAIN STABILITY CLASS	I	Any material, plain or gently undulating topography					
	II		Moderately steep rock slopes				
			Fans and gentle slopes of any material				
	III		Irregular rock slopes with till or colluvial veneers				
				Moderate glaciofluvial slopes			
				Till or colluvial veneers or blankets, glaciofluvial scarps			
					Course textured talus, competent rock		
				Glaciolacustrine or Glaciomarine blankets or slopes			
	IV				Glaciolacustrine or glaciomarine blankets or slopes		
					Gullied till or colluvial blankets		
						Fine textured till or colluvial veneers or blankets. Till, colluvial, glaciolacustrine, glaciomarine slopes	

APPENDIX C
REVIEW OF PRECEDING GEOHAZARD MANAGEMENT PLAN PERFORMANCE AND RECOMMENDATIONS

C-1 INTRODUCTION

BGC reviewed the performance of the existing Brucejack GMP (Pretium Resources Inc., December 2016) which included a review of reported geohazard events at the site, the weather advisory levels and overall performance of the existing GMP. This Appendix summarizes this review and provides recommendations.

C-2 REVIEW OF GEOHAZARD REPORTING

C-2.1 Summary of Past Events

BGC understands Pretium Resources Inc. performed annual inspections and reports of geohazard events that occurred each year from 2016 through 2020 inclusive as required by the existing GMP. These inspections involved field observations and monitoring data (where applicable) across several geohazard areas on the mine site. BGC is aware of the following recorded geohazard events:

- Ten locations of access road flooding identified on Oct 10, 2015 (BGC, March 8, 2017). Occurred during/on day with weather advisory levels of “high or very high”
- One rock fall in 2016 along transmission line (BGC, March 8, 2017)
- One rock fall on access road (km 43, “Slasher”) March 5, 2015 (BGC, March 8, 2017), impacted vehicle.

Pretium Resources Inc.’s annual inspection reports for 2017, 2018, 2019 and 2020 did not report any geohazards events and BGC has no record of a 2021 inspection report or reports of events identified outside of annual inspections (Pretium Resources Inc., January 29, 2018; Pretium Resources Inc., November 12, 2018; SRK Consulting (Canada) Inc., March 20, 2020; SRK Consulting (Canada) Inc., March 12, 2021). BGC notes that no geohazard events have been reported in the mine study area covered by this updated GMP. BGC assumes based on experience in similar and nearby terrain that smaller scale geohazard events or events of small consequence likely occurred but have not all been recorded for the mine site and related infrastructure.

Approximately 8 kilometres from Brucejack Mine in July 2021 a rock avalanche occurred on Canoe Glacier. This event is thought to have been triggered by an extreme heat event (Menounos et al., 2021) and demonstrates the potential magnitude of geohazard events possible in the Brucejack Area. Geohazard event reporting will be of critical importance to the continued operations of Brucejack Mine going forward. Event records improves preparedness for future events and allows safety protocols to be updated to evolving site conditions.

C-2.2 Geohazard Reporting Recommendations

BGC has modified the existing reporting guidance and associated forms to increase ease of use and reporting. BGC recommends Newcrest consider the implementation of a mobile geohazard reporting application in the future for mine operation personnel. A mobile application would make geohazard reporting more accessible in the field, where and when geohazards are first

identified. BGC also anticipates the use of a mobile application would increase geohazard data collection across the mine site. A mobile reporting application could be integrated with BGC's Cambio online data management solution used by other Newcrest operations.

C-3 REVIEW OF SUGGESTED WEATHER ADVISORTY LEVELS

The following section is a review of the weather advisory levels implemented by the existing Brucejack GMP and corresponding meteorological data collected near Brucejack since it's issuance.

C-3.1 Meteorological Data

Rainfall events can be an important trigger for geohazard processes. The existing GMP characterizes base case mine weather advisory levels per the matrix outlined in Table C-1. Four-week antecedent rainfall and "storm" precipitation values define the weather advisory levels. A "storm" precipitation is defined as events where more than 1 mm of precipitation falls per hour for at least six consecutive hours, per the existing GMP. A summary of four-week antecedent precipitation data and base case weather advisory levels issued by the storm events recorded at the weather station BJ VOK near the mine site is presented in Figure C-1 for the timeframe spanning December 2, 2014 to November 17, 2022. A summary of the noted storm events, their duration and corresponding weather advisory levels is presented in Table C-2.

Table C-1 Weather advisory level matrix based on the observed 4-week antecedent precipitation and the forecasted storm precipitation.

		Storm Precipitation (mm)				
		< 25	**25-50**	**50-75**	**75-100**	**>100**
4-week Antecedent (mm)	<150	**L**	**M**	**M**	**H**	**VH**
	150-200	**M**	**M**	**H**	**VH**	**VH**
	>200	**M**	**H**	**VH**	**VH**	**VH**

Figure C-1 Precipitation time-series and storm events near Brucejack Mine with associated base case weather advisory level.

Table C-2 Summary of storm events near Brucejack Mine and their base case weather advisory level.

	Weather Advisory Level				Total
	Low	Moderate	High	Very High	
Number of Storm Events	18	55	6	8	87
Avg. Duration (hours)	7.1	8.8	12.0	20.0	9.7

Precipitation has a complex relationship with geohazard processes, with other meteorological factors such as snow level and temperature affecting the likelihood that rainfall storms will trigger geohazard events. These factors are applied to adjust the base case weather advisory level associated with the storm events outlined in Table 5-1. The following conditions are outlined in the Geohazard Management Plan (Pretium Resources Inc., December 2016) to account for the influence of these additional meteorological factors:

1. If temperatures are ≤ 0°C, lower the risk level by two unless already Low.

2. If temperatures are greater than 5°C and there is snow on the ground, raise the risk level by one unless already Very High.

A summary of the noted storm events, their duration and corresponding adjusted weather advisory levels is presented in Table 5-1 for the timeframe spanning December 2, 2014 to November 17, 2022.

Table C-3 Adjusted weather advisory level summary for storm events between 2014 and 2022 near Brucejack Mine.

	Weather Advisory Level				Total
	Low	Moderate	High	Very High	
Adjusted Number of Storm Events	38	28	13	8	87

Contrasted in Table C-2 and Table C-3, the storm hazard modifying conditions outlined have significant impact on the ranking of rainfall events. There was a storm event on October 10, 2015 ranked Very High (base case) and High (adjusted) resulted in ten areas of flooding along the access road (BGC, March 8, 2017). No other annual monitoring reports consulted by BGC (Pretium Resources Inc., January 29, 2018; November 12, 2018; SRK Consulting (Canada) Inc., March 20, 2020; March 12, 2021) mentioned records of geohazard events in areas outside the mine site. Improved record-keeping and reporting of geohazard events along access roads will improve the connection between rainfall thresholds and geohazard events.

C-3.2 Weather Advisory Level Recommendations

Based on the guidance provided by the 2016 GMP, storm event “Very High” weather level advisories have been issued eight times over approximately seven years, from the timeframe spanning December 2, 2014 to November 17, 2022. Limited record of geohazard events in the mentioned timeframe prevents further calibration or assessment of the advisory levels accuracy and performance. Given this limited availability of calibration events and the reasonable distribution of weather advisory levels summarized in Table C-1 for the storms identified in the studied timeframe, BGC recommends maintaining the current GMP weather level advisory guidelines in the updated 2023 GMP prepared for Newcrest.

C-4 RECOMMENDATIONS

BGC recommends the following based on review of the existing GMP and its performance:

- Newcrest facilities inspections should be performed by Newcrest personnel following “High” weather advisory level storm events to assess potential geohazard occurrences
- Newcrest facilities inspections should be performed by qualified professional(s) following “Very High” weather advisory level storm events to assess potential geohazard occurrences or increased geohazard level

- Mitigative measures taken (e.g., scaling, ditch clearing, bolting) in response to or in prevention of geohazard events should be documented and made available for review during annual geohazard inspections. This includes follow up actions completed in response to prior geohazard review inspections, even if no follow up action was performed.

These recommendations have been applied to the updated GMP (main body of this report).

BGC recommends the following for future works at the Newcrest Brucejack facilities:

- Expand the area covered by the GMP to encompass all Brucejack facilities including but not limited to access roads and transmission lines
- Reconciling Stantec (October 31, 2014) and BGC (July 31, 2015) terrain mapping and geohazard assessment information generated for the site transmission lines
- Further study to quantify the geohazard risk posed to existing infrastructure, mine operations and workers safety within the study area by the identified hazards.

APPENDIX D
GEOHAZARD EVENT REPORTING FORMS

Ministry of Energy and Mines

ADVICE OF GEOTECHNICAL INCIDENT

PART A: To be completed by mine management to document geotechnical incidents.

APPLICABILITY OF THIS FORM

This form applies to any geotechnical incident classified as a dangerous occurrence or to any geotechnical incident that requires changes to an existing standard operating procedure or the creation of a site-specific safe work plan. In addition, any multi-bench pit slope failure, spoil failure resulting in full loss of the crest berm, or dam embankment instability (regardless of size) is to be documented on this form. This form is not intended for single bench failures fully captured by catchment berms or for "sliver" failures on spoils not resulting in a dangerous occurrence.

PREVIOUS EDITIONS

The first three editions of the Brucejack Mine Ground Control Management Plan (GCMP) (i.e. through 2016) were prepared by BGC Engineering Inc. The 2018 edition of the GCMP reflects updates and other revisions by Brucejack Gold Mine Senior Geotechnical Engineers (Dr. Woo Shin, P.Eng. and Allan Chan, P.Eng.). The 2019 edition of the GCMP was prepared by BGC Engineering Inc. The 2020 edition of the GCMP reflects updates and other revisions by Brucejack Gold Mine Senior Geotechnical Engineers (Dr. Woo Shin, P.Eng. and Dr. Baoyao Tang, P.Eng.) and was reviewed by SRK Consultants Inc. The 2021 edition of the GCMP reflects updates and other revisions by Brucejack Gold Mine Senior Geotechnical Engineers (Dr. Woo Shin, P.Eng. and Dr. Baoyao Tang, P.Eng.). The 2022 edition of the GCMP reflects updates and other revisions by Brucejack Mine Senior Geotechnical Engineer (Dr. Woo Shin, P.Eng.).

1 INTRODUCTION

The Brucejack Ground Control Management Plan (GCMP) is the authoritative record of data, information, and systems used to manage ground control matters at the Brucejack Mine.

Key objectives of the GCMP are as follows:

- Reduce and / or mitigate the risks of uncontrolled ground failure; and
- Contribute to the development and maintenance of a safe and productive mining environment.

These objectives are achieved through:

- Clear definitions of Ground Control roles and responsibilities for key individuals;
- On-going assessment of the mine's geotechnical conditions, and evaluation of ground control risks;
- Design and implementation of ground control management systems;
- Development of Standard Work Procedures (SWP) that address ground control issues;
- Communication of ground control matters and potential hazards within the workforce;
- Ground monitoring systems;
- Ground support testing;
- Internal and external auditing; and
- GCMP review, and scheduled updating.

The Brucejack GCMP consists of four sections:

- Section 1. Roles and Accountabilities;
- Section 2. Ground Control Management at Brucejack;
- Section 3. Implementation of the GCMP; and
- Section 4. Verification of the GCMP.

An archive of drawings, data, and information relating to the GCMP is attached to this document, including the following:

- **Drawings:**
  - Drawing 01. Location Map;
  - Drawing 02. Developed Prospects and Past Producers Near Brucejack Project, Plan Map;

- Drawing 03. Interpreted Groundwater Elevation Map;
- Drawing 04. Laboratory Intact Rock Strength Testing Results;
- Drawing 05. Hoek-Brown Strength Curves for Geotechnical Units; and
- Drawing 06. Structural Geology Plan Map.

- **Appendices**
  - Appendix A. Drill Hole Summary Logs;
  - Appendix B. Drill Hole and Underground Mapping Stereonets;
  - Appendix C. Laboratory Testing Results;
  - Appendix D. Point Load Testing;
  - Appendix E. Rock Mass Characterization;
  - Appendix F. Brucejack Fault Zone Summary;
  - Appendix G. Mine Domain Stereonets;
  - Appendix H. 2019 Geotechnical Data Review
  - Appendix I. Stope Stability and Support Assessment & Stope Design Review;
  - Appendix J. Stope Dilution Assessment;
  - Appendix K. Site Inspection Reports;
  - Appendix L. Minimum Ground Support Standards; and
  - Appendix M. Full-Width Undercut Support.
  - Appendix N. Geotechnical Assessment of Secondary Stopes
  - Appendix O. Ground Support System- Development into/beside Paste Backfill
- **Supporting Information**
  - I. Brucejack Ground Support Product Specifications and Installation Guidelines;
  - II. Current Mining Contractor Safety and Ground Control Documentation; and
  - III. Pretium Resources Inc. (Pretium) Safety and Ground Control Documentation.

The Brucejack Mine GCMP has been updated in 2020 by Brucejack Mine Technical Services Department Senior Geotechnical Engineers (Dr. Woo Shin and Dr. Baoyao Tang), in 2019 by BGC Engineering Inc. (BGC), and in 2017 and 2018 by Brucejack Mine Technical Services Department Senior Geotechnical Engineers (Dr. Woo Shin and Allan Chan). BGC authored previous editions. The GCMP is reviewed annually and updated as appropriate by Professional Engineer(s) in accordance with Mines Act Permit M-243 Conditions C.2(d).

2 GROUND CONTROL ROLES AND RESPONSIBILITIES

Roles and Responsibilities for ground control at the Brucejack Mine are outlined in Table 2-1.

Table 2-1 Ground Control Roles and Responsibilities at Brucejack

Title	Responsibility
Mine Manager	• Fulfill regulatory, Code, and mine permit requirements for ground control matters; • Confirm ground control is adequately considered in design and operation of the mine; • Appoint task-trained / qualified persons with ground control knowledge and experience; • Support implementation and on-going review of the GCMP; • Provide adequate resources to fulfill the requirements of the GCMP; • Support subordinates and review progress on ground control responsibilities; and • Support development and implementation of Safe Work Procedures (SOPs).
Mine Operations Superintendent	• Support subordinates in ground control responsibilities; • Confirm development and implementation of SOPs; • Provide support to shift supervisors and technical services in resolving ground control issues; and • Investigate and address GCMP and SOP deficiencies.
Mining Contractor Mine Superintendent	• Appoint task-trained / qualified persons with ground control knowledge and experience; • Provide and document adequate task and ground control training to mine personnel; • Support subordinates in ground control responsibilities; • Confirm suitable equipment, tools, and materials are supplied and maintained; • Confirm development and implementation of SOPs; • Provide support to shift supervisors and technical services in resolving ground control issues; and
Mining Contractor Shift Supervisor	• Confirm that work sites and travel ways are maintained to safe and acceptable standards; • Confirm suitable equipment, tools, and materials are supplied and maintained; • Inspect, monitor, and communicate on ground conditions in work areas; • Confirm SOPs and ground control procedures are understood and followed by mine personnel; and • Ensure mine contractor personnel are task trained and competent in their duties.
Pretium Chief Mine Engineer	• Confirm implementation of the GCMP; • Provide resources to support and update the GCMP; • Confirm geotechnical and ground control aspects are considered in design, planning, execution; and • Investigate and address GCMP and SOP deficiencies.
Pretium Senior	• Collect and analyze data to determine geotechnical inputs for mine planning and

Title	Responsibility
Geotechnical Engineer **Pretim Senior Geotechnical Engineer**	design. Interpret and communicate findings and recommendations; • Develop and maintain a ground condition model, based on the geological and geotechnical setting and the underground mining environment; • Determine ground control design criteria to support mine planning; • Provide ground support / reinforcement designs based on the ground condition model; • Conduct, record, and archive regular ground assessments of work areas; • Monitor, record, interpret, and communicate on excavation surveillance data; • Inspect and document ground falls, zones of potential geotechnical concern; • Conduct ground control training; • Conduct, document, and archive ground control audits, reviews, and quality assurance programs; and • Regularly review and update the GCMP.
Mine Geologist	• Collect geology and geotechnical data to determine inputs for mine planning and design. Analyze, interpret, and communicate findings and recommendations; • Provide geology support and input to the Underground Manager, Mining Engineers, and Mine planners; • Complete field investigation tasks (mapping, drilling, logging) to support ground control management; and • Develop, maintain, and update the mine geology model.
Pretium / Mining Contractor Safety Coordinators	• Conduct regular safety inspections of work places; • Develop, approve, and review SOPs and conduct compliance audits; • Investigate and report on safety incidents; and • Help supervision ensure mine personnel are appropriately trained and competent to safely carry out proscribed tasks.
Miners, Operators, Underground Personnel	• Comply with SOPs; • Inspect and monitor ground conditions. If unsafe, withdraw and barricade area, and notify the Shift Supervisor; • Undertake 'Ground Awareness' training; • Undertake task specific training; • Understand and implement ground support standards; and • Communicate on ground control issues.

3 GROUND CONTROL MANAGEMENT FOR MINE DESIGN AND PLANNING

Ground Control Management is integral to mining at Brucejack and will be considered over the life of the mine, during the design, planning, development, and operational stages. Ground control management will be approached in a systematic manner, and take into account the following factors:

- **Geological and Geotechnical Factors:**
  - Distribution of rock types;
  - Distribution, orientation, and condition of regional and local geologic structures;
  - Ore zone location and grade;
  - Geotechnical conditions of the rock mass;
  - Rock strength parameters (uniaxial compressive strength, cohesion and friction angle, etc.);
  - In-situ stress conditions and anticipated changes arising from mining;
  - Groundwater conditions; and
  - Ground response to mining determined from monitoring and surveillance.
- **Mining Factors:**
  - Excavation dimensions;
  - Mining method and sequencing;
  - Backfill type and strength;
  - Required use of excavation;
  - Required service life of zone or excavation; and
  - Ground support requirements, equipment, and constraints.

This section presents a summary of the existing project geology and geotechnical datasets, and provides a description of ground control analysis and design tasks and systems used to support mine design and planning activities. An objective of the discussion presented in this section is to provide a template for incorporating geology, geotechnical, and ground control data and information into the mine plan on an ongoing basis.

Current mine plans and designs at Brucejack are based in part on results of site investigations and geotechnical assessments completed by BGC and Brucejack Technical Services (BTS) personnel. The assessments included rock mass characterization tasks, structural geology interpretations, excavation and pillar stability analyses, and ground support designs and audits.

Geotechnical site investigations completed to support the current designs included: geological and geotechnical drilling and logging, oriented drill core measurements, borehole televiewer surveys,

laboratory testing of rock core and discontinuity samples, and installation of borehole instrumentation to measure groundwater pressures. Geotechnical mapping of the underground workings was also completed to provide structural geology and rock mechanics information. Additionally, the geotechnical performance of excavations within the mine are regularly inspected and verified by Pretim, the mining contractor, and BGC.

A comprehensive presentation of the data and information summarized in this section is presented in BGC's May 2013 "Underground Rock Mechanics Assessment" (BGC, 2013a), completed in support of the Brucejack Project's Feasibility Study. For reference purposes, select Appendices and Drawings from that document are attached to this GCMP (Appendices A, C to K, Drawings 1 - 6). Since BGC's 2013 study, a number of location specific assessments and inspections have been completed (BGC, 2013b; BGC, 2014a; BGC, 2015a; BGC, 2016b, 2016c; BGC, 2017b, 2017c; BGC, 2018b). Summary reports for those inspections and assessments, including the geotechnical data, are provided in the Appendices.

3.1 GEOLOGY AND GEOTECHNICAL DATABASE

This section summarizes geology and geotechnical data sources and information used to support the development of the GCMP.

3.1.1 Drill Holes

Data from approximately 6,000 drill holes advanced between 2010 and 2022 are included in the mine database. In total, the dataset includes over 890,000 m of geological and geotechnical core logging information from NQ, HQ, and PQ diameter core, collected throughout the Brucejack Mine area by Pretium and their predecessors.

Fourteen holes (~6,000 m) were drilled specifically for geotechnical purposes and logged by or under the direct supervision of BGC.

3.1.2 Geotechnical Core Logging

Geotechnical core logging completed for the Brucejack Mine can be divided into seven phases:

1. Data collected by Silver Standard during the 2010 exploration drilling programs;
2. Data collected by Pretium during the 2011 exploration drilling program;
3. Data collected by Pretium during the 2012 exploration drilling program with training from BGC to facilitate the collection of additional geotechnical data during logging; and
4. Data collected by or under the direct supervision of BGC during the 2010 and 2012 geotechnical drilling programs.
5. Data collected by or under the direct supervision of BGC during the 2014 and 2015 geotechnical drilling programs.
6. Data collected by Pretium between the 2016 and 2022 exploration drilling program.

7. Data collected by Newcrest between the March 2022 and August 2022 exploration drilling program

Data from the 2012 thru 2015 drilling programs collected by BGC and data from the 2016 to 2022 drilling program collected by Pretium, and data from the March 2022 to August 2022 drilling program collected by Newcrest represent the most complete geotechnical drill hole dataset available for the Mine. Parameters and observations logged by BGC per core interval include:

- Total grade (ISRM, 1978);
- Average core recovery;
- Rock quality designation (RQD) (Deere and Deere, 1988);
- Longest stick;
- Number of discontinuities;
- Number of discontinuity sets;
- Strength grade (ISRM, 1978);
- Weathering joint condition (Bieniawski, 1976); and
- Point load testing.

These data, combined with detailed discontinuity logs, and underground mapping data and observations, provide the basis for the rock mass characterizations completed by BGC and BTS. Summary geotechnical drill hole logs are provided in Appendix A. Data from the 2014/2015 underground inspections are provided in Appendices K.

3.1.3 Televiewer Surveys and Oriented Core

Data collected from acoustic and optical borehole televiewer surveys are the main source of sub-surface discontinuity orientation information for the Brucejack Mine. Eight of the ten geotechnical drill holes completed in 2010 and 2012 were surveyed and interpreted. During the 2012 drilling program, six holes were also oriented using the ACT II core orientation system to provide an independent check on the televiewer survey results. In 2014 and 2015, an additional four holes were drilled, geotechnically logged, and oriented (ACT II), for the purpose of assessing ground conditions near the Underground Crusher Chamber. The results of the ACT II orientation method were consistent with the televiewer results. The discontinuities measured during the televiewer surveys and oriented core drilling were compiled into structural domain stereonets, and are provided in Appendix G. An update of the VOK structural domains was completed in 2018 (BGC, 2018b) and 2019 (BGC, 2019a), and the updated stereonets are provided in Appendix I-1 and Appendix H.

Since 2020, 66 drill holes have been oriented using the ACT III core orientation system. The oriented core data is generally not used to model fault structure because orienting core in zones of broken core is problematic. The fault are modelled in a number of steps as follows. The initial step involves modelling zones of low RQD as volumes that represent damage zones associated with the faults.

Midplanes surfaces are then extracted from the damage zone volumes to represent the fault surfaces that offset lithologies and mineralization domains. The fault surfaces are then extruded from 0.25 to 0.75m for use in the RMR model. Updated 2022 RMR model can be found,

J:\Geo Engineer Share\RMR Model\RMR_Dec2022\rmr_simulation_Dec2022_sub_block_tri.bmf

3.1.4 Laboratory Testing

Laboratory testing of rock core samples and discontinuity surfaces from geotechnical drill holes was conducted in during all drilling programs. Tests completed include uniaxial compressive strength (UCS), Brazilian tensile strength (BTS), triaxial compressive strength, and small scale direct shear (DS).

Testing of fault gouge and soil-like materials recovered from the geotechnical drill holes included grain size analysis, hydrometer tests and Atterberg limits. In addition to samples collected from geotechnical drill holes, tests were completed on PQ-sized exploration drill holes stored at Pretium's core warehouse in Stewart, BC, to increase the number of test results for each lithology. Laboratory reports are provided in Appendix C.

3.1.5 Structural Geology Review

BGC referenced work completed by Earth Resource Surveys Inc. (ERSi) at the adjacent KSM property for regional structural geology interpretations. Lineations were mapped from color and black and white aerial photographs, LiDAR digital elevation model (DEM) data, and color orthophotographs. Ground-truthing of the lineament mapping study was completed by ERSi in September 2009 and August 2010. The results of this mapping have been used to develop an understanding of the regional structural fabric and to assist in the selection of design discontinuity sets.

3.1.6 Structural Mapping

The underground geotechnical designs at Brucejack are in part based on geotechnical mapping completed in 2012 by BGC in the de-watered underground workings previously mined by Newhawk Gold Mines Ltd. Where accessible, geological structures were mapped and their influence on excavation stability was evaluated. Over 1,000 structural measurements were collected from the portal, ramp, exploration drift and 1350 level. Information on the orientation, infilling, roughness, and persistence of the discontinuities was collected. Additional surface outcrop mapping and structural interpretations by Pretium were made available to BGC and were incorporated into the geotechnical database.

Since Brucejack commenced development in 2015, additional geologic and geotechnical data has been collected during mapping by the geologists and geotechnical engineers during the development cycle (Figure 3.1). The new data is used to regularly update the existing geotechnical database. A review of the geotechnical data (rock mass and geologic structure) collected since 2012 was completed by BGC in early 2019, and the results are summarized in Appendix H.

Table 3-1 Example of Geological and Geotechnical Mappings

3.1.7 Geotechnical Inspections

In January 2013, April 2014, April 2015, and May 2016, BGC completed annual geotechnical inspections of the Brucejack underground workings, with BTS completing regular underground inspections throughout mine development work since 2017. Geotechnical conditions throughout the mine were assessed on these occasions and ground control procedures and support practices were reviewed. The summary report for 2019 has been attached to the GCMP in Appendix K.

3.1.8 Other Relevant Data

Three dimensional (3D) geological models of the main lithologies and geological units have been interpreted by Pretium within the West Zone (WZ) and Valley of the Kings Zone (VOK). These interpretations have been used a basis for mine planning and design tasks. The 3D models are subject to ongoing review and updating from Pretium's geology department.

The Brucejack Fault Zone surface had been interpreted by previous owner Silver Standard for a 2010 PEA. BGC reviewed the drill hole intercepts from all drilling (geotechnical and exploration) to refine the interpretation of the Brucejack Fault Zone with respect to orientation, rock mass characteristics, and true thickness of the fault zone. Additional underground mapping and drilling by BTS during development work has further defined the location and character of the Brucejack Fault. Interpretations of this fault are discussed below. Geological maps and reports for the area were sourced from the B.C. Geological Survey (BCGS), Geological Survey of Canada (GSC), MinFile, and historic reports from previous owners (Newhawk, Silver Standard).

3.2 GEOLOGY AND GEOTECHNICAL MODELS

A full discussion of the Brucejack Property geology is presented in several regulatory submissions (43-101 Technical Reports) and company reports on file with Pretium. For context, a summary is provided below.

3.2.1 Geological Setting

The Brucejack Property is underlain by Upper Triassic volcaniclastic and epiclastic sedimentary rocks of the Stuhini Group and Lower to Middle Jurassic volcanic, volcaniclastic, and sedimentary rocks of the Hazelton Group. Unuk River Member andesites of the Hazelton Group are the most important host rocks to the gold and silver bearing quartz veins.

Multiple zones of alteration have been noted in the Mine area. Alteration assemblages vary with proximity to deformation events, but sericitic alteration is pervasive throughout. Carbonate, chlorite, and silica alteration are also common.

The Brucejack Mine area has been divided into structural domains separated by location and major faults and folds, as shown in Drawing 06. Within each domain, design discontinuity sets have been interpreted for both the ore zone and wall rock, from borehole televiewer surveys, oriented core measurements, underground mapping, outcrop mapping, and regional structural interpretations. Sources of data are indicated in Drawing 06. Summary stereonets for each domain are provided in Appendix G, H, and I.

Observations from outcrop and underground mapping demonstrate that localized variations in joint set orientations and intensity occur due to folding and faulting. These local variations may not be observed in statistically significant quantities in downhole data due to infrequency of measurements. In each structural domain, the design sets constitute approximately 40% to 45% of the total poles measured. The remaining "random" discontinuities do not cluster into dip or dip direction patterns and are unlikely to represent site scale structural fabric; however they demonstrate wide structural variability across the site. Since discreet discontinuities are present in practically all orientations it can be reasonably assumed that adversely oriented structures may be present around all excavations.

3.2.2 Major Faults and Regional Structure

The Brucejack Mine area includes major faults mapped by various sources. Reports available through MINFILE were reviewed and associated maps were digitized to compile site and regional scale fault traces around the Mine site. Data from those sources were supplemented by a review of

the structural geology of the region completed by ESRi (2010) for the adjacent KSM property, and with ongoing mapping by Pretium's geology department. Major faults and lineaments identified to date are summarized in Table 3.2.

Table 3-2 Major Geologic Structure in the Brucejack Mine Area

Scale	Structure	Strike (*)	Dip (*)	Orientation Source
Regional	Treaty Creek Lineament	291 or 111	-	ERSi, 2010
	Upper Treaty Glacier Lineament	310 or 130	-	ERSi, 2010
	Brucejack Fault Lineament	355	-	ERSi, 2010
		176	60-90	Newhawk, 1990
		356	60	Margolis, 1993
Site	Lancaster Fault	330	74	BGC Mapping, 2012
		023	80-85	Newhawk, 1990
	Sutcliffe Fault	036	86	Newhawk, 1990
		038	73	BGC Mapping, 2012
	Jaz Fault	204	40	BGC Mapping, 2012
		191	-	Newhawk, 1990
	Zorzi Fault	212	74	BGC Mapping, 2012
		200	-	Newhawk, 1990
	Babics Fault	141	83	BGC Mapping, 2012
		125	-	Newhawk, 1990
		122	75	Roach, 1991
	Rainy Fault	220-240	30-10	Pretium
	Ryne Fault	246	71	BGC Mapping, 2012
		213	-	Newhawk, 1990
	Maddux Fault	059	69	BGC Mapping, 2012 – 1350 Level Ore Drive
		048	73	BGC Mapping, 2012 – Ramp-Exploration Drift Intersection
		020	72	Roach, 1991
		020	-	Newhawk, 1990
	Not My Fault	312	-	Newhawk, 1990

	SW Fault	151	-	Newhawk, 1990
	Brucejack Fault	340	60-90	Newhawk, 1990, SSR NI 43-101
	Wobbegone Fault	237	-	Newhawk, 1990
	Grace Shear Zone	321	-	Newhawk, 1990

	Upper Thrust Fault	136	28	Pretium, 2015
	VOK Main Thrust Fault	100	33	Pretium, 2015

3.2.3 In-situ Stress

In-situ stress conditions, and related mining-induced changes to these conditions, may have a significant influence on excavation stability. However, due to the lack of consistency in the available data, it is not possible to estimate the orientation of the major horizontal principal stress direction at Brucejack. With regards to magnitude of principal stresses, it is considered appropriate to assume that horizontal stresses are higher than vertical in the near-surface region, particularly in mountainous regions such as the Brucejack Mine (McKinnon et al., 2002).

The following additional assumptions, which follow common practice in defining in-situ stresses (McKinnon et al., 2002), have been made:

- The principal axes of the in-situ stress field are horizontal and vertical.
- The orientations of the principal stresses in the horizontal plane do not vary with depth.
- The magnitude of the principal stresses vary linearly with depth below surface.

BGC and Pretium are cognisant of the importance of evolving ground stress conditions and their impact on the safety and productivity of mining activities at Brucejack.

A ground stress surveillance program is included as a component of the GCMP to better predict, monitor, and document in-situ and induced ground stress. Although significant stress-induced rockmass instability is not anticipated at current mining depths, the mountainous topography and large faults at Brucejack result in lower confidence estimates of in-situ stress and the potential for variation in in-situ stresses throughout the mine plan.

As mining proceeds and the extraction ratio increases, there is the potential for stress-induced rockmass instability to occur as the result of lower confidence in the in-situ stresses and convergence of stress in pillars due to mining. The early development of a ground stress surveillance program will facilitate the documentation of baseline data to support back-analysis and expeditious modification of the mine plan should stress-induced rockmass instability occur during the mine life. Potential risks arising from unknown or incorrectly quantified in-situ stress conditions include:

- under-estimating stress magnitudes, resulting in potentially hazardous mining conditions;
- poor stope performance and productivity;
- damage to permanent infrastructure;
- errors predicting and responding to 'over-stressed' and 'de-stressed' zones, ground deformation;
- errors determining causes and effective responses to ground failures;

- errors estimating stope and pillar dimensions; and
- errors determining the optimal mining sequence.

To mitigate these risks for the Brucejack Mine a number of elements have been incorporated into the mine designs and GCMP to account for the uncertainty. For example, conservative stress estimates and industry-tested empirical and analytical geotechnical techniques that inherently account for the uncertainty were used to determine 'allowable' stoping geometries and related mining layouts. These were supplemented by knowledgeable engineering judgement guided by significant operational experience with similar mining methods in similar ground conditions. In addition, a preliminary 3D Boundary Element Model was developed to broadly conceptualize the evolution of ground stress conditions throughout the mining cycle and identify potential locations of concern.

Most importantly, an observational 'mine and monitor' risk management system will be employed at Brucejack, as part of the GCMP. Details of this are presented in Section 4.4. If field observations and performance data indicate the development of un-anticipated / anomalous / elevated stress conditions, or growing uncertainties with respect to Pretium's understanding of evolving stress conditions, an in-situ stress measurement program should be re-considered at that time. Combined with an observational approach based on rock mass and ground support reactions, stress measurement data could be used to help refine and calibrate 2D and / or 3D numerical models to help guide mine planning decisions.

Brucejack mine on-site geotechnical team installed stress-meters for collecting stress measurement data in 2021 and 2022, and 3-dimwnsional stress back analysis was conducted in 2022 to evaluate the effect of stress distribution following the stope development procedure. Total 6 stress-meters were installed to three different stopes, VK_1050_14N-ELAT7_15L, VK_1200_30-WLAT12_28L, and VK_1140_24_16T. The instruments installed near the center point planned stope walls get the maximum stress release and concentration caused by developing underground openings. Stress monitoring data from two stopes in 1050 level and 1200 level were successfully collected but the monitoring data from 1140 level was not collected because of delayed stope development and changed actual stope location.

Map3D 3-dimensional boundary element stress analysis tool was used for the back analysis on the stress changes near VK_1050_14N-ELAT7_15L stope following stope development sequences. Figure 2 shows the stress distribution of major stress contour around stope. There are small stress concentration zones (red contour) at the back and bottom corner, but possible stress induced failure zone could not be observed from most of the stope wall areas.

Stress changes monitoring following stope development were shown in Figure 3.1 and stress analysis results were compared with stress-meter readings in Table 3.3. Stress measurement data and technical summary of the back analysis can be found,

Stress-meter reading:

J:\Engineering\Geotechnical\Instrumentation\Stressmeters\Instrument_Readings.xlsx

Technical summary of stress distribution back analysis:

J:\Engineering\Geotechnical\Instrumentation\Stressmeters\Summary of Stressmeter Monitoring.docx

(a) Stress monitoring from the wall of VK_1050_14N-ELAT7_15L Stope (Elev. 1065m)

(b) Stress monitoring from the wall of VK_1200_30-WLAT12_28L Stope (Elev. 1215m)

Figure 3.1 Stress change monitoring before/after stope developments

Table 3-3 Summary of stress distributions from monitoring and analysis

Stope Name		VK_1050_N14-ELAT7_15L		VK_1200_30-WLAT12_28L	
Direction of Stress to Stope Wall		Perpendicular	Parallel	Perpendicular	Parallel
Estimated in-situ Stress (MPa)		13.5		9.5	
Stress-	Initial Reading (MPa)	12.2	11.7	10.2	8.8

Meter	Stress after Stope (MPa)	10.5	9.5	8.3	6.2
Stress	Initial Reading (MPa)	13.0	10.0	-	-
Analysis	Stress after Stope (MPa)	1.1	7.0	-	-

3.2.4 Rock Mass Characterization and Geotechnical Units

The rock mass classification presented in this section is a summary of work completed as part of the Feasibility Study for Brucejack (2015), and forms the basis for the geotechnical underground designs.

Since Brucejack commenced development in 2015, additional geologic and geotechnical data has been collected during underground resource drilling, and from regular mapping by BTS geologists and geotechnical engineers. This new data is used to regularly update the existing geotechnical database. A review of the geotechnical data (rock mass and geologic structure) collected since 2012 was completed by BGC in early 2019, and the results are summarized in Appendix H, and shows that the new data are generally consistent with the historical rock mass classification data at Brucejack.

The rock mass at Brucejack has been divided into several "geotechnical units" based on the properties of the rock and the character of the discontinuities. The properties of each geotechnical unit are estimated with consideration of:

- Lithology and alteration grade;
- Intact rock properties, including intact strength, specific gravity, Hoek-Brown material constant (mi), Young's Modulus (Ei), and Poisson's ratio (v);
- Block size versus discontinuity density, or "blockiness";
- Condition of the discontinuities separating blocks of intact rock; and
- Fault-disturbed zones.

Geotechnical units identified in the West Zone (WZ) of the mine, in order of increasing competence, are as follows:

- The Fault Zone ("WZ FZ") unit comprises fault-disturbed rock identified by Pretium ("FZ" lithology), and less competent rock and faulting identified on BGC geotechnical drill hole logs (Appendix A). This unit is strong with fair rock quality designation (RQD) values and close to moderate discontinuity spacing.
- The Weathered Rock Zone ("WZ WRZ") unit comprises weathered near-surface rock as indicated on geotechnical and exploration drill hole logs (Appendix A). It is medium strong with good RQD values and moderate discontinuity spacing. It extends to a depth of between 10 to 50 m below surface.

- The Fresh Rock ("WZ FR") unit comprises all remaining rock mass, which is very strong with excellent RQD values and wide discontinuity spacing.

Geotechnical units identified in the Valley of the Kings (VOK) zone, in order of increasing competence, are as follows:

- The Fault Zone ("VOK FZ") unit comprises rock identified as fault-disturbed rock by Pretium ("FZ" lithology), and less competent rock and faulting identified on BGC geotechnical drill hole logs (Appendix A). This unit includes the Brucejack Fault Zone. It is strong with good RQD values and close discontinuity spacing.
- The Weathered Rock Zone ("VOK WRZ") unit comprises overburden material identified by Pretium and weathered near-surface rock indicated on geotechnical and exploration drill hole logs (Appendix A). This unit is medium strong with good RQD values and close discontinuity spacing. It extends to a depth of between 10 to 50 m below surface.
- Rock mass Domain 1 ("VOK D1") includes the Volcanosedimentary facies (argillite portion) ("ARG") geologic unit and is very strong with good RQD values and moderate discontinuity spacing.
- Rock mass Domain 2 ("VOK D2") includes the Bridge Zone Porphyry ("BZP1"), the Office Porphyry ("OFP1"), and Silicified Rock ("Silcap") geologic units, which are strong with excellent RQD values, and moderate discontinuity spacing.
- Rock mass Domain 3 ("VOK D3") includes the Volcaniclastics ("CONG"), Volcanosedimentary facies (sandstone-conglomerate portion) ("VSF"), S3-Trans ("Trans"), and ANDX ("V12") units, which are strong with excellent RQD values and wide discontinuity spacing.

A summary of intact rock properties for each geotechnical unit is presented in Table 3.3. A summary of rock mass classification data for each geotechnical unit is presented in Table 3.4. Supporting rock mass characterization data and information is contained in Appendix E.

The rock mass strength of each geotechnical unit has been estimated from the intact rock strength, blockiness, and discontinuity conditions.

Following industry practice, a rock mass rating (RMR) has been estimated for each unit. The RMR (Bieniawski, 1976) applies a score to each basic rock mass parameter and sums the scores for a total rating. This rating may be used with the design UCS, estimated *mi*, and assumed rock mass disturbance value to define the empirical Hoek-Brown failure envelope for each unit. These failure envelopes define the rock mass strength. The results for each geotechnical unit are shown in Table 3.5.

A RMR Vulcan block model is under development for the future ground stability assessment.

Table 3-4 Intact Rock Properties

Unit	UCS – Lab (MPa)	Average Is50 (MPa)	K	UCS - Design1 (MPa)	Brazilian Tensile Strength (MPa)	Hoek-Brown Material Constant, mi	Unit Weight (kN/m³)	Young's Modulus (GPa)	Poisson's Ratio
VOK FZ	N/A	N/A	N/A	89	N/A	12	26.3	30.0	0.20
VOK WRZ	N/A	N/A	11	50	N/A	17	28.6	3.8	0.18
VOK D1	N/A	N/A	N/A	116	N/A	17	27.2	30.5	0.20
VOK D2	107	7.3	15	95	9.4	19	27.1	30.8	0.11
VOK D3	77	6.0	13	73	5.0	26	27.3	30.0	0.14
WZ FZ	N/A	N/A	20	77	N/A	12	26.3	30.0	0.20
WZ WRZ	14	1.3	11	37	0.7	17	28.6	3.8	0.18
WZ FR	126	7.0	18	116	5.7	21	27.3	35.0	0.17

Notes:
1. Design UCS values have been estimated from the median Is50 values using laboratory-derived K values if available.
2. Unit weights are based on average results of specific gravity testing if available.
3. Hoek-Brown material constants have been derived based on a review of laboratory testing results.
4. Young's Modulus and Poisson's ratio have been estimated based on laboratory testing results if available.

Based on the data available, the WZ FR unit is estimated to have the highest rock mass strength while the WRZ and FZ units in both the VOK and WZ are estimated to have the lowest.

Table 3-5 Rock Mass Classification Summary

Geotechnical Unit	Length Observed (m)	Case[1]	RQD (%)	Fracture Intercept (m)	Blockiness Index Rating	Intact Strength: Logged Strength Grade	Intact Strength: Is_{50} (MPa)	Intact Strength: No. PLTs	Intact Strength: UCS[2] (MPa)	Intact Strength: Description	Intact Strength: Rating[2]	Joint Condition ('76)	RMR'76: Rating[3]	RMR'76: Description	Rock Mass Quality Q'

		Median	**87**	**0.430**	**34**	**4**	**4.7**		**50**	**Medium Strong**	**7**	**12**	**63**	**Good**	**13**
		Upper Range	96	1.010	41	4	5.8		61	Strong	7	20	78	Good	37
VOK D1 (ARG)	191	Lower Range	63	0.169	25	4	N/A	0	75	Strong	7	12	54	Fair	3
		Median	**87**	**0.339**	**34**	**5**	**N/A**		**116**	**Very Strong**	**12**	**16**	**72**	**Good**	**9**
		Upper Range	96	1.017	43	5	N/A		116	Very Strong	12	16	81	Very Good	53
VOK D2 (P1, RHY)	15817	Lower Range	72	0.289	28	4	5.3	206	77	Strong	7	16	61	Good	7
		Median	**91**	**0.533**	**37**	**4**	**6.5**		**95**	**Strong**	**7**	**16**	**70**	**Good**	**23**
		Upper Range	98	1.470	43	5	8.2		120	Very Strong	12	20	85	Very Good	74
VOK D3 (JR, TRS, ANDX)	47264	Lower Range	89	0.507	37	4	4.1	546	52	Strong	7	16	70	Good	18
		Median	**96**	**1.017**	**43**	**5**	**5.7**		**73**	**Strong**	**12**	**20**	**85**	**Very Good**	**52**
		Upper Range	99	2.990	49	5	7.3		93	Strong	12	25	96	Very Good	146

Notes:

1. Lower, median and upper values correspond to 25%, 50%, 75% cumulative fraction, respectively (Appendix E).

2. UCS has been estimated from point load index tests where available. VOK D1 strength is estimated from logged strength grade.

3. Groundwater rating of 10 has been assumed for the calculation of RMR'76.

Table 3-6 Rock Mass Strength and Deformation Modules

Unit	UCS (MPa)	GSI[2]	Unit Weight[3] (kN/m³)	m_i	m_b	S	E_{rm} (GPa)
VOK FZ	89	60	26.3	12	1.110	0.0023	5.13
VOK WRZ	50	63	28.6	17	1.879	0.0037	0.77
VOK D1	116	72	27.2	17	3.211	0.0144	9.76
VOK D2	95	70	27.1	19	3.186	0.0106	9.02
VOK D3	73	85	27.3	26	10.647	0.103	14.37
WZ FZ	77	57	26.3	12	0.928	0.0015	4.27
WZ WRZ	37	62	28.6	17	1.771	0.0032	0.73
WZ FR	116	85	27.3	21	8.599	0.103	16.77

Notes:
1. The Hoek-Brown failure criteria have been estimated assuming a disturbance factor ('D') of 0.8 for all units.
2. GSI is calculated from median rock mass parameters for each unit, where GSI = RMR '76.
3. Unit weights are based on average results of specific gravity testing when possible.
4. The Hoek-Brown curves have been derived using a sigma3 max. for a tunnel depth of 650 m.

The rock mass deformation modulus for each geotechnical unit has been estimated from the Young's modulus laboratory testing results of the intact rock, rock mass characterization, and assumed disturbance value (0.8) using the empirical methods of Hoek and Diederichs (2006). Higher deformation moduli result in less deformation of the rock mass when stress is applied.

3.2.5 Brucejack Fault

The Brucejack Fault lineament is currently one of three known major / regional structure that intersects the mining footprint (Drawing 06). By the end of 2019 and early 2020, the mine developments intersected the fault on two levels: 1080 L West side access drift and the 1320L Fault zone development heading. The Brucejack Fault is a northerly striking anastomosing fault zone located along the western margin of the study area and extends north to the Iskut River Fault. In places the lineament appears to be several sub-vertical to moderately (greater than 60°) dipping fault strands braided together. The zone has normal faulting with variable displacement estimated at 500 to 800 m (ERSi, 2010).

Pretium are currently developing an authoritative structural geology model for the Mine area. Prior to this, BGC reviewed drill hole data and core photographs in relation to the Brucejack Fault to characterize the properties of the Fault and review its proximity to the mine workings. BGC's work focused on identifying the orientation, thickness, and rock mass characteristics of the Fault.

The Brucejack Fault is comprised of a core of highly fractured rock with a zone of less fractured, fault-disturbed rock mass on either side. The width of the fault zone varies with depth and along strike from approximately 5 to 40 m. It is considered to be continuous along strike, and appears to dip slightly to the east above the 1,325 m elevation, and dip slightly west below the 1,325 m

elevation. For design purposes, the median RQD, Joint Condition, and point load index Is50 value (ISRM 1981) are 62%, 16, and 3.5 MPa, respectively, compared to the "excellent" median RQD value (91%) and median Is50 value of 6.5 MPa in the surrounding undisturbed VOK D2 rock mass.

The Fault zone rock mass also has a slightly higher degree of weathering / alteration intensity than undisturbed rock; however, both the Brucejack Fault Zone and undisturbed D2 rock mass have comparable median strength grades (R4) and median joint condition values (16).

The Brucejack Fault truncates several local-scale faults at the western extent of the Brucejack deposit, and thus has been interpreted as post-dating site-scale deformation events. Orientations parallel to the inferred Brucejack Fault lineament were commonly observed in downhole structural measurements across the property. All interpreted structural domains include sets oriented along the Brucejack Fault Zone with dips ranging from 56˚ to vertical.

Detailed descriptions and photographs of the Brucejack Fault can be found in Appendix F.

Based on the current mine plan, stopes and related development in the WZ are unlikely to intercept the Brucejack Fault. A pillar of greater than 100 m is inferred to exist between the WZ resource and the Brucejack Fault. This pillar thickness is considered sufficient to isolate the Brucejack Fault from significant mining related effects.

However, based on the current VOK zone mine plan the Brucejack Fault passes through the VOK footprint. At all planned working elevations, the resource blocks are continuous across the fault with the inference that stopes will be required proximal to, and likely within, the fault zone. Section 3.4.11 below discusses options for mining through the fault.

3.2.6 Rainy Fault

The Rainy Fault is a shallowly dipping structure that intersects the mine working in the main access drive between the WZ and VOK zones. The fault has a true thickness varying from 0.5 to 15 m, but generally between 0.5 m and 2 m thick.

Within 30 m of the crusher location, its orientation is approximately 35° dipping towards 230° based on the structural geology model provided by Pretium. Drilling and underground mapping work done as part of a recent study generally supports this interpretation, although the local orientation of the structure varies. Drilling and mapping intercepts suggest that splays are present.

The rock mass within the fault zone is generally very blocky with very poor to poor RQD (< 50%) and discontinuity spacing less than 0.20 m, but varies from relatively unbroken rock to compact silty/clayey gouge zones up to 1.5 m thick. Often the fault zone is comprised of multiple gouge zones separated by more competent zones of very blocky rock mass. Seepage conditions within the zone vary significantly, from dry to dripping.

3.2.7 *Hydrogeology*

Conceptualization of the groundwater flow system at the Brucejack site was required to provide estimates of groundwater inflow to the existing and future underground mine workings. These inflow estimates were used to size dewatering equipment and as input to the process water balance. The results of site investigations and hydrogeologic testing, ongoing groundwater level measurements, adit water treatment plant outflow measurements (approximately equal to adit inflow rates), and numerical modelling were used to better understand the groundwater flow system.

Site investigations were completed between 2010 and 2012 to evaluate the hydrogeologic conditions (e.g., hydraulic parameters of the bedrock, hydrostratigraphic units, and hydraulic gradients) in the vicinity of the underground workings, and included hydraulic response testing (e.g., packer testing, slug testing) and the installation of groundwater monitoring wells and vibrating wire piezometers. Data collected during site investigations are supplemented by ongoing monitoring of groundwater elevations and collection of water quality samples, and by data collected during adit dewatering activities at the site. The available data have been synthesized in a conceptual hydrogeologic model and represented in numerical groundwater flow models for quantitative analyses. The parameters and results of the calibrated numerical model are well constrained by the measured adit inflows which reflect the bulk hydraulic properties of the rock mass in the vicinity of the underground workings.

Details regarding the investigations and data used to develop the conceptual and numerical hydrogeologic models are summarized in BGC (2014b). Details of the numerical modelling approach and results are summarized in BGC (2015b, 2015c). Annual groundwater monitoring (BGC, 2016a; 2017a; 2018a) supports the assumption that the rockmass is dewatered by ongoing mine dewatering activities.

The hydrostratigraphy of the site is composed of a thin, discontinuous layer of glacial till or colluvium underlain by bedrock. Thicker overburden deposits are confined to local sections of the valley bottom and are not present in the vicinity of the underground mine.

The geometric mean of bedrock hydraulic conductivity estimates for test zones not interpreted to intersect faulted rock is 1.3×10^{-7} m/s, while the geometric mean of hydraulic conductivity estimates for test zones interpreted to intersect faulted rock is 3.8×10^{-7} m/s. Based on these data sets, it appears that the increased fracture frequency and rock mass alteration associated with fault zones may increase hydraulic conductivities by up to a factor of three in comparison to hydraulic conductivities of unfaulted rock. Site-wide, a general trend of decreasing bedrock hydraulic conductivity with depth is observed, although "point" scale hydraulic conductivity estimates from packer testing and single well response (slug) testing varies by 2 to 3 orders of magnitude at any given depth.

Surface topography has a pervasive influence on the groundwater flow system at the site. The elevation within the immediate Mine area ranges from approximately 1,350 m at the outlet of Brucejack Lake to over 2,000 m at the highest peaks. Measured groundwater elevations suggest that the water table is a subdued replica of topography, with depths to groundwater typically greater in

the uplands relative to the valley bottoms. Groundwater enters the flow system from an infiltration of precipitation and snowmelt, with lesser components supplied by surface water infiltration in lakes. Groundwater discharge zones are generally restricted to lakes, creeks, gullies, and breaks in slope.

3.3 BRUCEJACK MINE PLAN

The Brucejack Mine Plan supports the extraction of 3,800 t/d of ore through a combination of transverse Long Hole Open Stoping (LHOS) and longitudinal LHOS. Paste backfill is integral to the mine plan to maximize both orebody recovery and mining productivity. Modern trackless mobile equipment will be employed in the majority of mining activities.

The mine has two decline accesses – a decline from the VOK portal in close proximity to the concentrator is dedicated to conveying crushed ore directly to the concentrator via a ~650 m long conveyor. The West Zone portal is used to access a second decline, which is used for main access and egress. Figure 3.1 illustrates the decline configurations. The VOK ramp can be used as a waste haulage ramp when the West Zone ramp is shutdown or there are a large number of trucks hauling waste from the underground.

Figure 3-2 Perspective 3D view of Mine Plan (as of April 2020).

A fleet of LHDs and trucks is used for material loading and transport from the various underground working areas, through an internal ramp system that connects all levels to the centrally located crusher.

Permanent fans provide ventilation by forcing air down the declines, through the internal ramps, and exhausting to surface via dedicated raises that connect the various working levels to surface in each zone. The primary fans will be located at each of the main surface portals. Auxiliary fans are used for ventilating each level. An electric mine air heating system is used to take advantage of low electricity prices, with a propane system used to augment the electric system.

Ongoing development, to sustain ore production, will average approximately 850 m/mo. in the next five years, and then decrease to approximately 155 m/mo. in later years of the mine life.

Major underground infrastructure includes the underground crusher, conveyor system, ventilation raises, fans, heating system, pumping stations, electrical substations, a fuelling facility, explosives magazines, refuges, mine communications and other ancillary installations.

3.3.1 Access and Ramp Infrastructure

The VOK Portal decline join the main surface portal to the crusher tip and workshop area on the 1,330 Level. A main cross-over drive on the 1,330 Level joins the main decline to the two independent ramps servicing the VOK Zone and West Zone. Figure 3.1 illustrates the general development arrangement.

The internal ramps will connect all levels of the mine. The existing West Zone portal is used for underground access, and a second West Zone portal has been developed as a ventilation portal. The VOK ramp serves as the conveyor ramp and secondary access/egress point.

The southern ramp (VOK ramp) services the VOK and Galena Hill zones, and the northern ramp (West Zone ramp) services the West Zone, were both designed in a race-track configuration for safety, haulage efficiency, and to minimize wear on mobile equipment.

The use of an independent ramp for each zone–as opposed to a single ramp servicing both zones–was selected in the interest of access and capital efficiency, given that the West Zone ramp will not be required until mid-way through the mine life. For ease of entry and exit, ramps were designed with a 30 m turning radius and a 15% gradient, levelling out in proximity to a level access intersection. Passing bays were incorporated where required.

3.3.2 Level Development

Sublevels are accessed from the ramps on a 30 m vertical interval that is defined by the planned stoping heights. Footwall and hanging wall drives are set back a minimum of 22.5 m pillar thickness (i.e., 25 m from the centreline of the drift to the stope wall), whereas ramp development will be set back a minimum 50 m from the centreline of the ramp to the stope wall. This arrangement promotes long-term geotechnical stability and provides adequate space for the placement of a fresh air raise and other ancillary services between the ramp and level development, as required.

Sublevels generally terminate at a ventilation raise at one or both ends, permitting the exhaust of contaminated air from activity on the level. Figure 3.2 illustrates the VOK Zone sublevel arrangement in long section.

Figure 3-3 VOK Zone Sublevel Arrangement – Long Section

Level development follows the general strike of the various lenses, providing access to the mineralized zones in a manner that promotes transverse mining wherever possible and also add flexibility to mine longitudinally. Level development is generally in the hanging wall, with hanging wall drives typically including excavations for sumps, refuges, transformers, remucks, paste fill line, and raise accesses.

Stope access crosscuts will be on 15 m spacings, with the exception of those levels where sill extraction or near-surface weathered ore will be recovered in smaller units that are designed on 10 m spacings. Figure 3.3 illustrates typical level development requirements.

3.3.3 Excavation Dimensions

Table 3.6 provides excavation dimensions for standard development at Brucejack. All of these excavations are considered permanent mine excavations. A permanent excavation is any excavation with a life span greater than 6 months.

Table 3-7 Standard Excavation Dimensions

Parameter	Lateral							Vertical	
	Main Ramp	Access Drive	Cross Cut	Re-muck	Sump	Convyr. Ramp	VND	Esc. Raise	Vent. Raise
Width (m)	5.5	5.5	5.0	5.5	5.5	6.0	5.5	3.0	3.0
Height (m)	6.0	5.5	4.5	6.0	5.5	6.0	5.5	3.0	3.0

Arch (m)	1.0	1.0	0.0	1.0	1.0	1.0	1.0	0.0	0.0
Max. Grad. (%)	15	5	15	15	15	15	2	-	-

Figure 3-4 Typical Level Plan – 1,200 Level in the VOK Zone

3.3.4 Stope Cycle

The primary mining method will be transverse Long Hole Open Stope (LHOS) based on a standard primary/secondary sequence. No permanent pillars are currently planned, and maximum ore extraction will be targeted. Mining of the sills will expose the cemented backfill of the stopes in the block immediately above. They will be relatively more problematic to mine due to the effects of increasing ground stress and the overhead fill, with lower recovery, higher dilution, and higher costs anticipated.

The hanging wall drives will be completed, and a through ventilation circuit will be established before mining begins between any two levels.

A cross-cut will be driven from the hanging wall drive, through the centre of the stope, to the far ore contact on the undercut and overcut levels. The undercut level will have already been developed if stoping has progressed beyond the block starting level.

Cross-cuts on both levels will be cable-bolted (or equivalent) from the central access to pre-support the roof prior to full-width slashing of the entire stope footprint. Slashing to the adjacent stope boundaries will expose paste fill walls in the case of secondary stope extraction.

Full width slashing in primary stopes will permit parallel production hole drilling across the entire width of the stope, and will reduce the potential for ore in stope corners to fail to break to design due to inadequate free face or poor explosives distribution. Ore recovery will be higher than a fan drilling alternative (in the absence of full-width slashing). Given the significant value of Brucejack ore, high recovery was an overriding criterion in the design. Mining of secondary stopes with sidewalls of paste will be limited to 5 m wide overcuts with fan drilling or development of a cross-drift to allow for parallel drilling.

Once the stope footprint is slashed out, a 750 mm pilot hole will be drilled in the slot raise location. Production drilling will follow in the raise and slot area, followed by the production rings as drilling progresses towards the near ore contact.

The raise and slot are generally opened in five firings or less. Production blasting and mucking will proceed cyclically until the stope is depleted and all ore has been mucked out. Transverse LHOS is a non-entry method, with remote mucking of blasted ore required once the drawpoint brow is open to the extent where the operator may be exposed to uncontrolled sloughing from the stope cavity.

The empty stope will be remotely surveyed with cavity monitoring equipment. A barricade will be constructed in the drawpoint and the stope backfilled to just below the floor elevation of the top level. Crushed aggregate or ROM waste may be spread over the fill surface to reduce backfill dilution and increase trafficability of mucking equipment for the next lift of the stope.

The mining of sills and other areas, where top access is not available, will proceed in a similar manner; however, raise development and production drilling will be performed via up hole drilling from the bottom level.

Figure 3-5 Typical LHOS Design.

Note that mining of secondary stopes with sidewalls of paste will be limited to 5 m wide overcuts with fan drilling or development of a cross-drift to allow for parallel drilling.

Longitudinal LHOS will also be employed at the mine, although significantly less ore tonnage will be recovered by this method in comparison to transverse LHOS. The longitudinal method will be used in thinner areas of the orebody, where the thickness of mineralization is less than 15 m, to avoid excessive access development in waste. In contrast to transverse LHOS, mining will progress along the strike of the orebody to a common access point.

The overcut and undercut will be slashed to the footwall and hanging wall contacts. In all other respects, the stope cycle will be similar to transverse LHOS.

3.3.5 Stope Sequence

The mining sequence in any lens of a given mining block begins with the extraction of the primary stopes on the first (lowest) level. Wherever possible, the first primary stope will be located near the middle of the lens to develop a pattern of stope extraction that moves outwards to the extremities of the lens while progressing upwards towards the top. As confirmed by 3D numerical modeling, this generally promotes a favourable redistribution of ground stress, although many smaller lenses in the Brucejack orebody are either irregular in shape or of insufficient dimensions to properly develop this sequence.

When the adjacent primary stopes from the level above have been filled and cured, secondary stoping will commence. Figure 3.5 illustrates typical sequencing for the more massive lenses at Brucejack.

Figure 3-6 Example of Primary / Secondary LHOS Sequence

3.3.6 Backfilling

The primary means of backfilling will be paste fill, generated from unclassified mill tailings mixed with adequate cementitious binder to meet the strength requirements of re-exposure. Regular strength paste fill is commonly required where there will be re-exposure of vertical stope walls. The

design rationale and procedures for backfilling at Brucejack are documented in the Brucejack Backfill Management Plan.

Stopes that will not be re-exposed by adjacent mining may be backfilled with unconsolidated waste and/or by paste fill with sufficient binder to remove any risk of future liquefaction (low-strength paste fill).

High-strength paste fill will be required in the lower portion of all primary and secondary stopes that will be undercut by sill extraction from below. Table 3.7 tabulates the total projected paste fill volumes over the LOM by strength requirement and by binder dosage.

Table 3-8 LOM Paste fill Requirements

Paste Type	LOM Quantity (m^3)	28-day Strength (kPa)	Binder Dosage (%)	Density Dry Paste (t/m^3)	Mass Dry Paste (t)	Binder Required (t)
High-strength Paste	298,985	1,100	11/9.8	1.11	331,873	35,191
Regular Paste	1,408,585	350/250	6.4/5.5	1.11	1,563,529	96,460
Low-strength Paste	2,376,736	100	4.3	1.11	2,638,177	109,354
Total	**4,084,306**	**-**	**-**	**-**	**4,533,580**	**241,004**

The mine plan assumes that high-strength paste fill is a requirement in the lower portion of all primary and secondary stopes on the sill level, and regular strength paste fill will remain as a requirement for primary stopes where re-exposure of vertical stope walls will occur during secondary stope development. Only secondary stopes that will not be re-exposed by adjacent mining will be backfilled with unconsolidated waste rock (Figure 3.6). This requires around 15% of developed stope backfill with high strength paste with high percentage of cemented binder. Percentage of normal strength paste, and low strength paste backfill is 45% and 10% respectively. This plan can maximize total 30% of stopes to be filled with waste rock.

Figure 3-7 Schematic of Backfill Plan

3.4 UNDERGROUND ROCK MECHANICS ASSESSMENT

3.4.1 Methodology

BGC's underground rock mechanics assessment methodology is based on industry standard techniques. BGC has:

- Estimated achievable stope spans and associated ground support requirements based on empirical stope stability design charts;
- Analyzed potential kinematic failure modes resulting from major geological discontinuities or persistent rock mass fabrics, and developed associated ground support requirements; and
- Assessed pillar stability conditions using estimates of pillar strength and induced stresses, using analytical and numerical design tools.

3.4.2 Primary and Secondary Stope Designs

BGC has developed recommendations for unsupported and supported hydraulic radii and ground support to assist with the development of stoping design criteria. The empirical "Stability Graph" method (Hutchinson and Diederichs, 1996, and Nickson et al., 1992, after Potvin, 1988) was used to

estimate acceptable mining dimensions for the stope backs and hanging walls. Geotechnical and representative stope geometry parameters are combined to determine a "Stability Number" (N'), defined by:

$$N' = Q' \; x \; A \; x \; B \; x \; C$$

Where:

- Q' is a rock mass classification parameter;
- A is a measure of the ratio of intact rock strength to applied stress;
- B is a measure of the relative orientation of dominant structure with respect to the excavation surface; and
- C is a measure of the influence of gravity on the stability of the face being considered.

The Q classification system is frequently simplified to include only factors dependent on the rock mass, ignoring environmental considerations such as water and active stresses. The resulting rating will give the same assessment for the same rock conditions at different depths and hydro-geological states. Q' is the modified Q classification value with Jw and SRF set to 1. Modern design approaches account for the influence of stress in the design steps and it would be incorrect to assess these factors twice by including them in the rock mass classification.

$$Q' = \frac{RQD}{Jn} \times \frac{Jr}{Ja}$$

Parameter A is estimated for each face of the stope using the Stewart and Forsyth method, which estimates the maximum induced tangential stress acting at the centre of the stope face from an assumed stress regime (Stewart and Forsyth, 1995). As virgin stress has not been measured and World Stress Map data is unavailable in the region, stress conditions have been estimated empirically for the method using an assumed vertical stress given by the following equation, k = 2, and the ratio of opening dimensions being considered.

$$\sigma_v = unit\ weight\ x\ depth$$

Parameter B is dependent on the discontinuities most likely to cause instability. These discontinuities will intersect the stope face at shallow oblique angles. Due to structural variability in all structural domains it has been conservatively assumed that all excavations could have geologic structures that are sub-parallel to stope walls. Therefore, parameter B has been assumed to be 0.2 for all cases.

Parameter C is calculated using the orientation of the critical discontinuity set used to determine parameter B. However in cases where the discontinuity could contribute to both sliding and gravity fall, a conservative minimum value of C = 2 was used.

During the FS (BGC, 2013a) in an effort to simplify the results of the Stability Graph Method, so as to be useful to mine planners, conservative and base case Q' values of 10 and 40 respectively were

used to calculate the resultant hydraulic radii (Appendix I). Statistical observations of mapping data and the 110,000-plus m of core indicated that regardless of lithology, alteration, geological domain, or geotechnical unit, less than 20% of the data mapped or logged has Q' values less than 10. Similarly, over 50% of the rock has a Q' value of 40 or greater. These classes, and the resulting stope design recommendations, were intended to demonstrate the potential variability in rock mass quality and resultant achievable stope spans at Brucejack.

In 2019, BGC completed a review of geotechnical data collected at Brucejack since the FS (BGC, 2019a), and although the median values of the new data suggest the FS ranges are still valid (with 50% of the rock mass having Q' >10), the medians are close to the threshold value, and the upper range (i.e. higher quality rock) may be less common than initially assumed during previous assessments.

The resulting stability graph is used to match the calculated stability number (N') to maximum recommended unsupported and supported hydraulic radii. Stability charts have also been produced for stopes in weathered rock. Although stope dips of 78° were assumed for the stability analyses, most of the planned stopes at Brucejack are near vertical, and the hanging wall and foot walls are not clearly defined.

Based on the most recent work by BGC (2019a), for mine planning purposes, the conservative case hydraulic radii presented in Appendix I can be used as "base case" design values. BGC continues to recommend that Brucejack review stope designs on a case-by-case / package-by-package basis, particularly if optimized, larger, and less conservative stope dimensions (i.e. greater than "median" designs) are proposed to be implemented in the mine plan. Stope dilution estimates are provided in Appendix J.

Current designs are for nominal rock mass, absent of large-scale or controlling geologic structure. Wide 'Stable' spans intersected by geologic structure or poorer quality rock required enhanced / deep patterned support consisting of minimum 4.88 m long coupled Super Swellex or cement grouted cable bolts (0.7" diameter, bulbed, dual strand ~ 30-35 ton capacity/strand, nominally >50 t / hole installed capacity). If geologic structure is present (as observed in some of current secondary stopes) dead weight analysis of the rock wedge / block is required to confirm adequate bolt capacity.

3.4.3 Stope Ground Support

If mine planners elect to use "supported" case hydraulic radii, then the stopes must be supported with cable bolts or their equivalent. Empirical design charts (Hutchinson and Diederichs, 1996) were used to determine the minimum cable bolt lengths and spacings required for stability, and to minimize ravelling and dilution. Charts for stopes excavated in fresh rock are provided in Appendix I and I-1, respectively, and assume an equivalent square cable bolt pattern.

Given that no hanging wall development is planned, a modified cable bolt pattern will be required, whereby the cable bolts are installed from the footwall side of the topsill and bottomsill into the

hanging wall. This will result in a point anchor support approach to hanging wall support, and the cable bolts will be installed in a fan pattern to divide the hanging wall into smaller unsupported stable spans. As discussed by Nickson (1992), this type of support simulates a series of reinforced beams along the hanging wall.

Previous experience suggests that approximately 5 cable bolts per ring, with rings spaced every 1.5 - 2.5 m can be used for bolt density estimates. Cable bolt lengths will be designed and installed to exceed 25% of maximum unsupported span; for example, a hanging wall with an exposed face of 35 m between topsill and bottomsill would require a minimum cable bolt length of 9 m. The success of point anchor support is heavily dependent on block size, and designs will be calibrated with site specific data from observations of stope dilution when available.

For added versatility during mining operations, a study was conducted on the use of connectable Super Swellex (PM24C at 4.8m / 16' length) for stope span stability to achieve similar design objectives equivalent to cable bolts. Moreover, given the shorter-term nature of stopes, the Super Swellex was considered a good, practical option for this application. The details of this study, which was completed by BGC, are in Appendix M.

3.4.4 3D Stress Analysis

A number of preliminary 2D and 3D stress analyses models have been completed to date by BGC and the on-site geotechnical engineering team for the mine; these are considered suitable for studying the evolution of mining-induced stresses, but are not considered suitably calibrated to estimate precise magnitudes of stress, strain, or infer the relative degrees of rock mass damage resulting from failing / yielding rock (i.e., micro-cracking, spalling, on-going plastic deformation, and, in the extreme case, rock- bursting).

The model results can be reviewed with the goal of highlighting areas where stress is concentrating, where stress shadows (loss of confinement, or relaxation) are occurring, and where standoff distances or pillar thicknesses are not sufficient to isolate a critical openings from significant mining-induced stress changes.

The models limited capacity arises from the current level of knowledge (or lack thereof) regarding the 'final' mining sequence, in-situ stress conditions, local and intermediate-scale structural features and geotechnical 'zoning', etc. All of these can significantly constrain the extent to which the model can be used to accurately predict local and global rock mass behaviour during mine life.

3.4.5 Stand-off Distances

Minimum stand-off distances between excavations of 10 m, 25 m, and 50 m are recommended for the raises, ramps, and underground crusher, respectively. The recommended stope stand-off distance from all hanging wall drives is 25 m from the centreline of the drift to the stope wall.

3.4.6 Rib Pillars

The illustrations in Figure 3.7 are provided for context:

Figure 3-8 Pillar Schematics

The rib pillars between cross-cuts were designed to be in waste and therefore will not be recovered, but are considered temporary based on the short-term lifespan required for access to a given stope. The minimum recommended pillar width to height ratio for cross-cut rib pillars for the "base case" design is 1.1:1.0, and 3.3:1.0 for the "conservative case" design. If cross-cuts are developed within the weathered zone, the recommended rib pillar width to height ratios are 1.7:1. The rib pillars between the open stoping blocks are intended to give temporary support to the mining block until the primary stopes are backfilled and the pillar can be recovered in the form of a secondary stope. Using the pillar stability graph method developed by Hudyma (1988) and tributary loading theory, the minimum recommended secondary stope span (rib pillar thickness) to primary stope span for the "base case" stope design is 1:1 for sublevel intervals of 30 m.

Analysis of the "conservative / low strength case" indicates that higher pillar load to UCS ratios may develop in the pillar cores, resulting in an increased potential for progressive pillar damage, such as pillar cracking and or surface spalling, as Load to UCS ratios approach and exceed 0.5.

If such a case arises, a number of mitigation measures could be used to remedy potential rib pillar deterioration, including increased localized reinforcement of the pillars with bolts, screen, straps and / or shotcrete (where accessible), or alternatively, a change in the local excavation geometry and /or mining sequence.

3.4.7 Sill Pillars

The current design sill pillar thickness is 30 m. The numerical modelling analysis shows some relaxation in larger stope hanging walls, and stress concentrations in sill pillars within areas of the mine with denser stoping. The model shows that the bottom-up sequence concentrates stress in both

VOK Zone sill pillars. Yielding is likely to occur prior to recovering the entire sill pillar, and therefore achievable sill pillar recovery may be less than 100%. The West Zone sill pillar is interpreted to be stable except for stress concentration in the sill pillar abutments. Stress concentration in pillar abutments is common in mines using centre-out sequencing, and does not necessarily indicate stability problems prior to full extraction of the sill pillar.

3.4.8 Crown Pillar

To maximize crown pillar recovery, the minimum recommended crown pillar thickness for the West Zone and VOK Zone is 15 m, with a maximum recommended stope span of 10 m for all stopes immediately below the crown pillar. As the recommended maximum span is narrower than the transverse width of the mineralized zones, transverse stopes immediately below the crown must be tight-filled as much as practicable to reduce the potential for crown pillar collapse. The crown pillar will be supported with 6.0 m long single strand bulbed cable bolts on 2.5 m spacing.

3.4.9 Ground Support

Minimum ground support standards are shown in Appendix L. Ground support analyses for permanent "man-entry" and temporary "production" headings were conducted in each structural domain. Ground support designs were then refined based on operational considerations such as standardization of ground support. All mesh is assumed to be 100 mm x 100 mm x 4.0 mm (8 gauge) wire. The 0.7" cable bolts specified are assumed to have a minimum breaking strength of 339 kN, and the #7 resin-grouted rebar specified are assumed to have a minimum yield strength of 155KN and the breaking strength of 232KN. Double layers of mesh are used to strap pillars to avoid ground support installed by the jack leg. Example shotcrete designs are provided in the Supporting Information package.

Minimum ground support standards are summarised in Table 3.8. These support standards are provided for the average rock mass as Brucejack, with a RMR value ranging from 40 to 100. Ground support for other rock mass qualities in standard development headings are provided in the next section. All other openings (intersections, infrastructure, portals, raises, etc.) should be considered on a case-by-case basis.

Table 3-9 Brucejack Ground Support Recommendations for Average Rock Mass Quality (40<RMR <100)

Opening Type	Cross Section (w x h, m)		Ground Support Type	Length (m)	Spacing (m)	Mesh Estimate (%)	Additional Notes
Main access decline, ramps, and other haulage routes	5.5 x 6.0 (VOK ramp) 6 x 6 (conveyor ramp)	Back	Fully-grouted #7 Resin grouted rebar	2.4	1.8 x 1.8	100	Welded wire mesh will be installed in the back & extended to within 1.5m-3.0m of sill elevation down the walls, lagging min. 1 round behind only. All active faces to be screened 1.2m down from the back.
		Walls	Fully-grouted #7 Resin grouted rebar	2.4	1.8 x 1.8	70	
Level development	5.5 x 5.5	Back	Fully-grouted #7 Resin grouted rebar	2.4	1.8 x 1.8	100	Welded wire mesh will be installed in the back & extended to within 1.5m-3.0m of sill elevation down the walls, lagging min. 1 round behind only. All active faces to be screened 1.2m down from back.
		Walls	Fully-grouted #7 Resin grouted rebar	2.4	1.8 x 1.8	70	
Sumps	5.5 x 5.5 – 7.0	Back	Fully-grouted #7 Resin grouted rebar	2.4	1.8 x 1.8	100	Welded wire mesh will be installed in the back and 1.0 m down the walls
		Walls	Fully-grouted #7 Resin grouted rebar	2.4	1.8 x 1.8	20	
Historic development (if rehab. required)	3 x 3	Back	Fully-grouted #7 Resin grouted rebar	1.2	1.2 x 1.2	100	To be installed only if rehab. is required. Welded wire mesh will be installed in the back &extended w/in 1.5m of sill.
		Walls	Fully-grouted #7 Resin grouted rebar	1.2	1.2 x 1.2	20	
Intersections	Includes 6 x 5, 5 x 5, three-way, four-way, and herringbone layouts	Back	Pre-support: Fully-grouted #7 Resin grouted rebar	2.4	1.8 x 1.8	100	Welded wire mesh will be installed on the back and down to within 1.5m-3.0m of sill on each wall for all intersections with an effective span greater than 6 m. Double wrap each pillar with an additional screen.
		Back	Long support: Single strand 0.7" bulbed cable bolts, 1.0 m bulb spacing or 16′ connectable Swellex	6.0	2.5 x 2.5		
		Walls	Fully-grouted #7 Resin grouted rebar	2.1	1.8 x 1.8	70	
Cross-Cut Drives	5 x 4.5	Back	SS39 Split-Set	2.1	1.2 x 1.2	100	Welded wire mesh will be installed in the back & extend within 1.5m-3m of the sill elevation down the walls.
		Walls	SS39 Split-Set	2.1	1.2 x 1.2	70	
Full-width undercuts	5 x 5 pilot	Back	Pre-support: SS39 Split-Set	2.1	1.2 x 1.2	100	All support must be installed prior to slashing.
		Back	Long support: Single strand 0.7" bulbed cable bolts, 1.0 m bulb spacing or 16′ connectable Swellex	6.0	2.5 x 2.5		
	15 m wide full undercut (post-slash)	Back	SS39 Split-Set	2.1	1.2 x 1.2	100	
		Back	Long support: Single strand 0.7" bulbed cable bolts, 1.0 m bulb spacing or 16′ connectable Swellex as required	6.0	2.5 x 2.5		
		Walls	SS39 Split-Set	2.1	1.2 x 1.2	20	
Raises	3 x 3 m cross-section	All	Fully-grouted #7 Resin grouted rebar	1.2	0.8 x 0.8	50	Staggered spacing. Reduced support may be feasible if man-access is not permitted.[6]

Notes:

1. Wall bolts and screen must extend down to within 1.5 m of sill (floor), with wall screen lagging <u>no more than 3 round behind current face in all cases</u> during development.

2. Screen to be extended 1 screen width down from the back at all active headings for further loose retention at the face.

3. Surface support should be installed when excavation intersects relatively poorer ground, faults, more persistent joints or narrower joint spacing, soft joint walls, groundwater seepage points, or "dead" sounding difficult to scale material.

4. Use mesh estimate percentage for shotcrete cost estimating if shotcrete is preferred surface support.

5. Mesh and shotcrete will only be used in the exhaust raises if ground conditions require it, as there are no manways in these raises. The Fresh Air/Escapeway raises will be bolted and screened.

Table 3-10 Brucejack Ground Support Recommendations for Below Average Rock Mass Quality (RMR <40) [1, 2]

Rock Mass Class	Opening Type	Cross Section (w x h, m)		Ground Support Type	Length (m)	Spacing (m)	Mesh Estimate (%)	Additional Notes [3]
(RMR < 40) ("very poor" to "poor")	Main access decline, ramps, and other haulage routes	5.5 x 6 (VOK ramp) 6 x 6 (conveyor ramp)	Back	Fully-grouted #7 Resin grouted rebar Long support: Single strand 0.7" bulbed cable bolts, 1.0 m bulb spacing as required	2.4	1.2 x 1.2	100	Welded wire mesh with 50 mm of shotcrete across the back and walls to within 1.5 m of floor. All active faces to be screened 1.2m down face from back.
			Walls	Fully-grouted #7 Resin grouted rebar	2.4	1.2 x 1.2	100	
	Level development	5.5 x 5.5 5.0 x 4.5	Back	Fully-grouted #7 Resin grouted rebar Long support: Single strand 0.7" bulbed cable bolts, 1.0 m bulb spacing as required	2.4	1.2 x 1.2	100	Welded wire mesh with 50 mm of shotcrete across the back and walls to within 1.5 m of floor. All active faces to be screened 1.2m down face from back.
			Walls	Fully-grouted #7 Resin grouted rebar	2.4	1.2 x 1.2	100	

Notes:

1. *Ground support for excavations not reflected in the table should be reviewed on a case-by-case basis.*
2. *Alternative ground support materials might be required to deal with gouge and muddy ground where resin rebar is not suitable.*
3. *It may be advantageous to apply the shotcrete prior to mesh and rebar installation when exposed ground is to be soft, laminated, or highly fractured.*
4. *Extra ground support might be required based on the exposed ground conditions as per geotechnical engineer's judgement.*

Historic excavations will be recommissioned during the development of the mine. A historic excavation will be visually inspected by the Chief Mine Engineer or designate prior to first-entry by any personnel. The rock mass and existing ground support will be visually assessed for degradation, and, if it is determined that rehabilitation is required, rehabilitation will be carried out prior to recommissioning the excavation. If a historic excavation is rehabilitated, the ground support installed will meet the standards summarized in Table 3.8. Sample ground support installation procedures and specifications are included in Supporting Information Package I and II.

3.4.9.1 Ground Support for Variable Rock Mass Qualities in Standard Development Headings

As discussed above, the ground support summarized in Table 3.8 were designed for the average rock mass quality at Brucejack, which is RMR values 40 to 100. Ground support recommendations for standard development areas where RMR are less than 40 are provided in Table 3.9 and Trigger Action Response Plan (TARP) for standard drifts and intersection developments in different ground conditions are summarized in Table 3.10. All other excavations should be considered on a case-by-case basis.

3.4.10 Full-width Undercuts

The mine planners plan full-width undercutting of select primary stopes. Ground support recommendations are provided in Table 3.8 with recommendations for full-width undercuts provided in Appendix M. Primary stopes should be tight-filled as best as possible.

3.4.11 Intersection Pillar Noses

The pillar noses in intersection area need to be supported by proper bolting and screen depends on ground condition to minimize intersection zone. Minimum support with wire mesh screen pinned by 2.1m long split sets down to 1.5m from sill of pillar in fair to good condition of ground. The pillar nose in poor condition with sub-vertical discontinuities required coverage of double layers screen down to 1.5m with split sets from sill. Additional 50 mm of shotcrete are also required for the intersection pillars in possible progressive sloughing condition of ground.

3.4.12 Ground Support for Mining through Mine-Scale Fault Zones

All developments through large (mine-scale) fault zones will require support with fully grouted #7 resin grouted rebar bolts or swellex bolts on a 1.2 m square pattern. Full coverage (sill to sill) of welded wire mesh and 50 mm of shotcrete is also recommended. Stopes will be excavated in isolation and backfilled prior to any other production openings within the fault zone. The rock mass within the fault zone is not competent enough to form adequate rib or sill pillar strength between stopes. In each case, stopes will be constrained to either the host or fault disturbed rock. Excavations bridging the boundary will have unplanned dilution along the contact. The preliminary recommendation for maximum supported back hydraulic radii is 2.5 (10 m by 10 m), and maximum unsupported hanging wall hydraulic radii is 3.75 (10 m by 30 m), for stopes within the fault zone. Cable bolt support consisting of 6 m single or double strand bulbed cable bolts on a 2.5 m square spacing in the back is recommended.

3.4.13 Ground Support for Mining through/beside Paste Backfill

When drift develops through paste backfill, the drift should be excavated with arched back with straight wall height around 4m before the curve starts. Development will be advanced in 2.0m round length. 50 mm thick of shotcrete will be applied after mucking. Giving a 6-hour shotcrete curing time before bolting and screening is to start. 2.1 m long split sets are to be installed on a 1.0 m square pattern with screen coverage from sill to sill. Then advance for another round. When apply shotcrete to the newly exposed paste backfill, the previously installed bolt and screen for the last round should be covered with the 50 mm thick of shotcrete also. Details of the development sequence and support patterns are shown in the Appendix O.

When developing besides paste backfill, the development sequence and ground support requirements are shown in Appendix O. All drifts developing beside paste and have exposed paste wall will require additional support with 2.1 m long split sets on a 1.2 m square pattern and full coverage of welded wire mesh for the paste exposure as a primary support standard. 50 mm thick of shotcrete before or after primary support may also be required as per on-site geotechnical engineer's discretion. All developments also have paste exposure at the back more than 1.0 m wide, the drift need to be considered as a mining through paste and will require following support standard for mining through paste backfill.

3.4.14 Surface Raise Locations

The raise locations were chosen to avoid fault-disturbed rock and minimize intersection of weathered rock. The recommended pillar thickness between a raise and nearby development or production openings, including the decline access ramp.

Table 3-11 Brucejack Ground Support Trigger Action Response Plan (TARP)

Ground Condition		Risk	Opening Type	Dim (mxm)	Rock Bolt			Wire Mesh	Additional Support
					Type	L (m)	S (mxm)		
Fair to Good (40<RMR<100)		Low	Main Ramp	5.5 x 6.0	Rebar	2.4	1.8 x 1.8	Up to 3.0m From Sill	
		Low	Level Drift	5.5 x 5.5	Rebar	2.4	1.8 x 1.8	Up to 3.0m From Sill	
		Low	Waste Drift	5.0 x 5.0	Rebar	2.4	1.8 x 1.8	Up to 3.0m From Sill	
		Low	Ore Drift	5.0 x 5.0	Split Set	2.1	1.8 x 1.8	Up to 3.0m From Sill	
		Med	Int. A	7.0 – 10.0	Rebar	2.4	1.8 x 1.8	Up to 3.0m From Sill	6.0m Cable bolts
		High	Int. B	10.0 – 15.0	Rebar	2.4	1.8 x 1.8	Up to 3.0m From Sill	6.0m Cable bolts
Extremely Poor to Poor (RMR<40)		Med	Main Ramp	5.5 x 6.0	Rebar	2.4	1.2 x 1.2	Up to 1.5m From Sill	6.0m cable bolts as Req. Shotcrete as Req.
		Med	Level Drift	5.5 x 5.5	Rebar	2.4	1.2 x 1.2	Up to 1.5m From Sill	6.0m cable bolts as Req. Shotcrete as Req.
		Med	Waste Drift	5.0 x 5.0	Rebar	2.4	1.2 x 1.2	Up to 1.5m From Sill	6.0m cable bolts as Req. Shotcrete as Req.
		Med	Ore Drift	5.0 x 5.0	Split Set	2.1	1.2 x 1.2	Up to 1.5m From Sill	4.9m Connectables as Req. Shotcrete as Req.
		High	Int. A	7.0 – 10.0	Rebar	2.4	1.2 x 1.2	Up to 1.5m From Sill	12.0m Cable bolts Shotcrete
		Critical	Int. B	D > 10.0	***Possible intersection with D > 10m in poor ground need to be relocated or develop with separate ground support plan***				

3.4.15 Underground Infrastructure Bearing Capacity and Anchorage

Three (3) methods were used to evaluate preliminary ultimate and allowable bearing capacities for underground infrastructure at Brucejack. These include:

- US Army Corps of Engineers (USACE) / Peck Hanson Thornburn Method for Bearing Capacity in Jointed Rock Masses (1994);
- Widjojo and Kulhawy's (2004) Bearing Capacity Method for Strip Footings on Jointed Rock Masses; and
- Finite Element Modeling (RS3 Rocscience, 2016).

For all methods, a factor of safety of 3 has been applied to the 'Ultimate Bearing Capacity' (q_{ult}) to determine the "Allowable Bearing Capacity" (q_{allow}):

$$q_{allow} = q_{ult}/3$$

For the analyses the following assumptions were made:

- foundation footings are located on the surface of the bedrock (i.e., not buried); and
- foundations are not affected by groundwater conditions.

The results varied somewhat depending on the method used; they have been reviewed and evaluated to determine 'reasonable' values of q_{ult} and q_{allow}. These 'preliminary' values are presented in Table 3.10, and are considered valid for static, transient, and dynamic conditions. The values are to be confirmed upon final excavation of the rock mass at the specified infrastructure locations.

Table 3-12 Ultimate and Allowable Bearing Capacity (Preliminary)

Ultimate Bearing Capacity q_{ult}	Allowable Bearing Capacity q_{allow}
2.0 MPa / 290 psi	0.67 MPa / 97 psi

Table 3-13 Ground Support Recommendations for Mine Infrastructure

Area	Dimension (w x h x l) (m)	Design Factor of Safety	Lifespan	Support
Cap Magazine	5.5 x 5.5 x 10.0	2	LOM	#7 fully grouted resin rebar; 2.4 m length; 1.8 m square spacing. Welded wire mesh, 100% coverage on back and walls, coated with minimum 2" plain shotcrete.
Crusher Chamber – Lower level (Bin)	11.5 x 16.5 x 21.4	2	LOM	#7 fully grouted resin rebar; 2.4 m length; 1.8 m square spacing. Welded wire mesh, 100% coverage on back and walls, coated with minimum 2″ plain shotcrete. Double-strand 0.7″ bulbed cable bolts: Walls: 5.0 m length, 2.5 m square spacing, 1.0 m bulb spacing Back: 5.0 m length, 2.5 m square spacing, 1.0 m bulb spacing Confining surface support (e.g., steel or heavy gauge mesh straps) recommended for all noses and benches within the excavation.
Crusher Chamber – Coarse Ore Bin (between Grizzly and Bin)	7.5 x 21.5 x 6.0	2	LOM	#7 fully grouted resin rebar; 2.4 m length; 1.8 m square spacing. Welded wire mesh, 100% coverage on back and walls, coated with minimum 2″ plain shotcrete. Double-strand 0.7″ bulbed cable bolts: Walls: 5.0 m length, 2.5 m square spacing, 1.0 m bulb spacing Confining surface support (e.g., steel or heavy gauge mesh straps) recommended for all noses and benches within the excavation.
Crusher Chamber – Upper level (Grizzly station)	11.6 x 8.0 x 15.0	2	LOM	#7 fully grouted resin rebar; 2.4 m length; 1.8 m square spacing. Welded wire mesh, 100% coverage on back and walls, coated with minimum 2″ plain shotcrete Double-strand 0.7″ bulbed cable bolts: Walls: 5.0 m length, 2.5 m square spacing, 1.0 m bulb spacing Back: 5.0 m length, 2.5 m square spacing, 1.0 m bulb spacing Confining surface support (e.g., steel or heavy gauge mesh straps) recommended for all noses and benches within the excavation.
Fuel and Lube Station	6.0 x 5.5	2	LOM	#7 fully grouted resin rebar; 2.4 m length; 1.8 m square spacing. Welded wire mesh, 100% coverage on back and walls, coated with minimum 2" plain shotcrete.

(continued)

Area	Dimension (w x h x l) (m)	Design Factor of Safety	Lifespan	Support
Service Bay, Maintenance Bay, and Tire Bay	6.0 x 5.5	2	LOM	#7 fully grouted resin rebar: 2.4 m length; 1.8 m square spacing. Welded wire mesh, 100% coverage on back and walls, coated with minimum 2" plain shotcrete.
Powder Magazine	5.5 x 5.5 x 10	2	LOM	#7 fully grouted resin rebar; 2.4 m length; 1.8 m square spacing. Welded wire mesh, 100% coverage on back and walls, coated with minimum 2" plain shotcrete.
Refuge Station and Offices	5.5 x 5.5 x 25	2	LOM	#7 fully grouted resin rebar: 2.4 m length; 1.8 m square spacing. Welded wire mesh, 100% coverage on back and walls, coated with minimum 2" plain shotcrete.
Warehouse	6.0 x 5.5	2	LOM	#7 fully grouted resin rebar; 2.4 m length; 1.8 m square spacing. Welded wire mesh, 100% coverage on back and walls, coated with minimum 2" plain shotcrete.

Rock Anchors

Rock anchor loads are determined by evaluating safety factor requirements for specific structures and equipment, operating under a wide-range of potential operating conditions. Anchors may be designed for a variety of stability considerations including foundation uplift, overturning and / or sliding. The anchor concepts presented in the discussion below require further review once final designs are determined for Brucejack.

Anchor depth depends largely upon the condition and quality of the rock mass into which the anchors are to be installed, and the desired anchor pattern (i.e., a single anchor, a single row of anchors, or multiple rows of anchors) (refer to Figure 3.8). The 'anchor depth' is defined as the anchor length necessary to develop the anchor force required for stability.

Figure 3-9 Anchor Depth for Single Anchor vs. Row of Anchors

Per Littlejohn and Bruce (1977), in fractured rock the strength of the rock mass subjected to a tensile force (the anchor force) cannot typically be relied upon to provide the necessary pullout / uplift resistance. For this reason, only the weight of the affected rock is usually considered in design. Based on this assumption, the anchor depth is computed as follows:

$$D = \sqrt[3]{\frac{3 * F * P}{\gamma * \pi}}$$

Where:

- D = required depth of anchorage;
- F = appropriate factor of safety;

- P = anchor force required for stability;
- g = unit mass of rock.

Note that it is assumed that the in-situ stresses are zero.

Similarly, for a single row of anchors in fractured rock typically only the weight of the affected wedge of rock is relied upon to provide the necessary resistance. For a single row of anchors, spaced 's' units apart, in fractured rock, the anchorage depth is computed as follows:

$$D = \sqrt{\frac{F * P}{\gamma * s}}$$

For multiple rows of anchors, with rows spaced 'L' units apart, again, only the weight of the affected rock mass resists the anchor force. The following equation can be used to determine the anchorage depth:

$$D = \frac{F * P}{\gamma * L * s}$$

Bond Strength

The design of grouted anchorages must insure against failure between the anchor and the grout, as well as between the grout and the rock. Experience and numerous pull-out tests have shown that the bond developed between the anchor and the grout is typically twice that developed between the grout and the rock. Therefore, primary emphasis in design and analysis is placed upon the grout/rock interface.

Values of ultimate bond strength are normally determined from shear strength data, or field pull-out tests. In the absence of such tests, the ultimate bond stress is often taken as 1/10 of the uniaxial compressive strength of the rock or grout (whichever is less) (Littlejohn 1977) up to a maximum value of 4.2 MPa (i.e., 600 psi). This results in ultimate bond stresses of 4.0 MPa and 2.0 MPa respectively. The working bond stress is exactly half of the ultimate bond stress if a safety factor of 2 is applied. The anchor load P is related to the fixed anchor design by the following:

$$P = \pi d L \tau$$

Where:

- P = Anchor Load;
- d = Effective anchor diameter (including annulus);
- L = Fixed anchor length; and
- τ = Working bond stress.

Under most conditions adequate bond strength is developed within the first 1.0 m of embedded length such that the anchor capacity becomes the weakest element in the anchorage system.

Preliminary anchor depths for floor anchors were determined for Brucejack using the above noted industry standard techniques. Table 3.12 and Table 3.13 present a summary of anchor depths for a variety of uplift loads and anchor patterns, for Safety Factors of 1.5 and 2.0 respectively.

Table 3-14 Anchor Depths for a Variety of Loads, Anchor Patterns, and FOSs (1.5)

Uplift Load (t)	Single Anchor Depth (m)[1]	Single Row Anchor Spacing (m)	Single Row of Anchors Depth (m)[1]	Perpendicular Spacing (m)	Multiple Anchor Depth (m)[1,2]
5	1.38	0.75	1.92	0.75	-
5	1.38	1.75	1.26	1.75	0.91
10	1.74	0.75	2.72	0.75	-
10	1.74	1.75	1.78	1.75	1.81
20	2.20	0.75	3.85	0.75	-
20	2.20	1.75	2.52	1.75	3.63
30	2.52	0.75	4.71	0.75	-
30	2.52	1.75	3.09	1.75	5.44
40	2.77	0.75	5.44	0.75	-
40	2.77	1.75	3.56	1.75	7.26

Notes:
1. Anchor depth calculations assume a Safety Factor of 1.5.
2. Multiple anchors generally require > ~ 1 m spacing for reasonable anchor depths.

Table 3-15Anchor Depths for a Variety of Loads, Anchor Patterns, and FOSs (2.0)

Uplift Load (t)	Single Anchor Depth (m)[1]	Single Row Anchor Spacing (m)	Single Row of Anchors Depth (m)[1]	Perpendicular Spacing (m)	Multiple Anchor Depth (m)[1,2]
5	1.52	0.75	2.22	0.75	-
5	1.52	1.75	1.45	1.75	1.21
10	1.92	0.75	3.14	0.75	-
10	1.92	1.75	2.06	1.75	2.42
20	2.42	0.75	4.44	0.75	-
20	2.42	1.75	2.91	1.75	4.84
30	2.77	0.75	5.44	0.75	-
30	2.77	1.75	3.56	1.75	7.26
40	3.05	0.75	6.29	0.75	-
40	3.05	1.75	4.11	1.75	9.67

Notes:
1. Anchor depth calculations assume a Safety Factor of 2.0.
2. Multiple anchors generally require > ~ 1 m spacing for reasonable anchor depths.

Based on a review of preliminary designs and geotechnical data, the following anchor arrangement and capacities are recommended for 'Side Wall Platform Supports' at Brucejack:

- 2 x 1.8 m long #7 Dywidag rock bolts (galv.) per support 'point', with bolts spaced ~ 30 cm apart, resulting in ~ 2 x 200 KN min tensile yield, and, ~ 2 x 115 KN shearing resistance, per 'point'.

Similarly, the following anchor arrangement and capacities are recommended for 'Roof Crane Supports' at Brucejack:

- 2 x 1.8 m long #7 Dywidag rock bolts (galv.) per mount point, spaced on 3 m centres along the length of both the LHS and RHS crane rails (i.e., each mount point for the crane rails consists of a group of 2 x #7 Dywidag bolts, providing 2 x 200 KN min tensile yield per 'mount point'.

A high-strength micro-fine cement grout or equivalent anchor resin is recommended as a bonding agent. The BTS group will determine an appropriate product. Anchor installation guidelines including the manufacturer's recommended drill hole diameter are attached to this document.

The preliminary anchorage depths noted above should be confirmed pending final designs and once loading conditions are known.

Installation / Quality Control

Proper installation of the rock anchors is required to achieve adequate performance characteristics. Installation recommendations, and bolt (and resin) technical specifications from relevant product manufacturers have been attached to this document. In addition to these, a trigger-response table for installation specific to Brucejack is provided (Table 3.14). It is recommended that anchors and accessories used in 'permanent' installations be galvanized to protect against corrosion.

Table 3-16 Rock Anchor Support Installation - Trigger / Response

Trigger Condition	Response
Normal drilling conditions	Proceed with installation per recommended guidelines
Soft / weak ground encountered, hole completed to depth	Proceed with installation per recommended guidelines, confirm acceptable installation, record and report location to Shift Supervisor / Geotechnical Engineer
Soft / weak ground encountered, unable to advance hole to depth	If possible, relocate hole collar within available area. If not possible, record and report location to Shift Supervisor / Geotechnical Engineer
Excessive cracking / separation of shotcrete during drilling, installation	Contact shift supervisor
Change of ground condition in same location over time	Contact shift supervisor / Geotechnical Engineer
Excessive water inflows from hole	Contact shift supervisor / Geotechnical Engineer
Fines / Mud / Water in hole prevents resin from setting, bolts rotate but do not set	Contact shift supervisor / Geotechnical Engineer, expect to use a secondary grouting method

4 IMPLEMENTING THE GROUND CONTROL MANAGEMENT PLAN

This section describes the procedures and systems for training, communication, analysis, interpretation and records management regarding ground control matters at Brucejack.

4.1 GROUND CONTROL TRAINING

Relevant ground control training shall be provided to all mine personnel, commensurate with the work to be undertaken and the responsibilities associated with a particular role. Ground Control training is conducted through a number of forums including:

- Underground Induction. The underground induction is presented by the Mining Contractor's Training and Safety Department. The induction contains basic information on working in an underground environment.
- Ground Awareness Training. All underground employees will receive Ground Awareness Training. For current employees this training shall be retaken every year. This training aims to equip underground personnel with the ability to identify geotechnical hazards and the skills to react appropriately. Includes Rock Scaling Examinations and Sign-offs.
- Operator Training. The operators will be required to be skilled and competent in the use of underground equipment. The mining contractor's Training and Safety Department shall ensure that a comprehensive training and assessment program is implemented, with completion records maintained in an accessible format.
- Safe Work Procedures (SWP's). Safe Work Procedures are currently being developed jointly by Pretim and the mining contractor for regular / recurrent tasks underground. The Mine Manager will authorize all SWP's before implementation, and along with other Key Individuals, supervise their implementation and review / update.
- Geotechnical Hazard Information Sessions. When new or unique geotechnical hazards are encountered in the mine the Geotechnical Engineer will present information on the hazard to the workforce. This can be done at the same time as the Shift Change Meeting, or a suitable alternative. Content from the information sessions will be noted in a 'Geotechnical Hazards Register' to ensure a record exists for the specific Ground Control issue.

4.2 GROUND CONTROL COMMUNICATION

It is the responsibility of all mine workers to communicate ground control matters to the appropriate person. These communications take various forms, including meetings, ground control information sessions, job hazard assessments, notice boards, mine plans, and memorandums.

4.2.1 Meetings

4.2.1.1 Daily Site Safety Meeting

The purpose of the meeting is to inform all mine site personnel of safety related items specific to work activities planned for the day. If Ground Control Management issues are likely to impact any, or all, of these tasks, the Daily Safety Meeting is an appropriate venue for any worker to initiate discussions regarding concerns, risks, mitigation strategies, etc.

4.2.1.2 Daily Shift Change Meeting

The purpose of the meeting is to plan and schedule tasks for the upcoming shift. The daily task list is based on work scheduled in the weekly planning meeting, as well as other daily items. During the handover between shifts, the Shift Supervisor of the outgoing shift provides information on the current workplace ground conditions, including any geotechnical hazards. Allocation of ground control tasks to mine personnel and operators will be made by the oncoming Shift Supervisor at this meeting.

The Geologist/Geotechnical Engineer must attend the meeting if information on ground control needs to be communicated to miners and operators.

4.2.1.3 Daily Production Meeting

The purpose of this meeting is to review daily development targets and potential production delays. The Geologist/Geotechnical Engineer can use this meeting to highlight issues with ground control that may impact production activities. During this meeting any reported hazards shall be discussed and responsibility assigned to the appropriate departments.

4.2.1.4 Weekly Planning Meeting

The purpose of the weekly planning meeting is to plan and coordinate the work efforts of all departments for the upcoming week. The geologist/geotechnical engineer attends this meeting and provides information on the expected ground conditions, ground support requirements, diamond drilling, quality assurance and quality control, etc. From this meeting a weekly plan is formulated for Ground Control Management.

4.2.2 Ground Control Information Sessions

The geotechnical engineer will develop and direct information sessions discussing geotechnical hazards at Brucejack Mine, and arrange for such sessions to be given on a regular basis to all underground personnel. The talks will focus on specific Ground Control Management items and related geotechnical issues.

4.2.3 Job Hazard Assessments

Ground Control issues and risks will be considered and evaluated as part of all Job Hazard Assessments (JHAs). A JHA Template is included in the supporting information attached to the

GCMP. Specific plans and actions aimed at reducing and / or mitigating risks will be outlined in detail in the JHA. The geotechnical engineer shall contribute relevant guidance and facilitate ground control discussions during Job Hazard Assessment sessions for unique work tasks.

4.2.4 Ground Control Notice Board

A Ground Control Notice Board will be maintained in the Shift Change Room. This space will be used to present information on Ground Control issues such as changes to support standards and details of actions carried out to address and mitigate geotechnical hazards.

A copy of the Ground Control Management Plan and current IFC Mine Plans shall be kept in this area for any mine personnel to access and review.

4.2.5 Official Development Drawing (Mine Plans)

Official Development Drawings are issued by Pretium to the mining contractor for construction / execution. The plans are signed off by the Mine Planning Engineer, Senior/Chief Mine Geologist, the Geotechnical Engineer, the Senior /Chief Engineer /the mining contractor's Superintendent and the Mine Captain/Superintendent.

No development will occur without an IFC Mine Plan for a particular heading or stope, nor without an assessment of the ground conditions and anticipated support requirements. The plan will show any unique geotechnical conditions that may be encountered as well as any 'geotechnical holds' that have been identified. The 'geotechnical holds' will also be stored and maintained electronically in an accessible format by the Geotechnical Engineer.

Where a 'geotechnical hold' is issued, the Geotechnical Engineer will coordinate with Pretium technical services and operations groups, and the mining contractor, to determine how development is to proceed. A written instruction will be issued ('Variation of Ground Support' Form), and attached to the relevant IFC Mine Plan.

4.2.6 Variation of Ground Support Form

No development shall proceed with ground support different from the standards indicated in the current GCMP, unless a 'Variation to Ground Support' form has been completed by the Geotechnical Engineer and signed by the underground Mine Manager. The form will be attached to the relevant IFC mine plan. This applies to situations where less ground support is deemed appropriate, or when customized and / or enhanced ground support is required based on the triggers or conditions described above.

4.2.7 Rehabilitation Memorandums

Rehabilitation Memorandums shall be issued for areas where, upon inspection, ground support does not achieve the established standards, or where ground conditions dictate that additional

support is required. This may occur due to equipment damage, mining induced damage, poor mining practices, or exposure of unanticipated ground conditions during development.

An example of a typical rehabilitation memorandum and related information is Geotechnical Inspection Memo (GIM) issued based on daily inspection by on-site geotechnical engineers and examples of the GIM can be found,

> *J:\Engineering\Geotechnical\Geotechnical Log Book\2023\02 - Fev\11\GIM20230211-VK_1500 Sump Long Support Plan - Final Version.pptx*

4.2.8 Reporting Ground Control Hazards

4.2.8.1 Mine Personnel and Operators

Mine personnel and Operators immediately report any geotechnical hazards to their Supervisors. They also record geotechnical hazards on their 'Field level Hazard Assessment' cards that get filled in daily, prior to commencing any task. These cards prompt the worker to check the excavation and ground conditions prior to work. An example of the card is presented in Supporting Information Package II.

If geotechnical hazards are encountered that prevent the Operator from working safely the Shift Boss should be contacted. The Shift Boss must record the geotechnical hazard in his or her log book. The Shift Boss must report the hazard to the Superintendent and the Geotechnical Engineer. A description of all reported geotechnical hazards is kept in the Geotechnical Log Book in the Shift Boss' office, and digitally on the Geotechnical drive on the computer network. The Register will include information on the actions taken to rectify the hazard and the feedback given to the Shift Boss and Operator.

4.2.8.2 Other Underground Personnel

Other personnel underground are expected to report geotechnical hazards directly to their supervisors or to the Geotechnical Engineer. These shall also be entered into the ' Geology / Geotechnical Log Book.

4.3 STANDARD OPERATING PROCEDURES (SOPS)

Developing, implementing, and auditing ground control SOPs is a core responsibility of Key Individuals under the GCMP.

The Mining Contractor is primarily responsible for the development of SOP's. Pretium are also currently developing a number of supplemental SOP's to address tasks and conditions unique to the Brucejack Mine. Relevant SOP's are to be incorporated into the GCMP as they are developed.

4.4 OBSERVING AND ASSESSING GROUND BEHAVIOUR

4.4.1 Rock Mass Quality

The quality of the rock mass within the mine is expected to range from predominantly 'good to fair' quality rock. The locations of 'poor to very poor' rock are typically associated with fault disturbed zones. For the purpose of choosing appropriate support for the expected rock mass conditions, the

rock mass quality has therefore been divided into 'good to fair' and 'poor to very poor' quality rock. This classification is not related to the empirical schemes proposed in the previous sections, but is a simplified method that allows mine personnel to quickly assess the ground quality based on visual observations. In cases where drill hole data is available and the quality of the rock can be pre-determined, locations of 'fair to poor' ground will be indicated on IFC Mine Plans. Definitions of 'Fair to Poor' and 'Good to Fair' ground are given in Table 4.1.

Table 4-1 Definition of Poor and Good Ground

Poor to Very Poor Ground (has ANY of these characteristics)	Good to Fair Ground (has ALL of these characteristics)
Excessive barring / scaling down is or was required, or ground is drummy and cannot be scaled	Minimal scaling required
Significant blast damage to the rock mass	Minimal overbreak from blasting
Significant stress related damage (bagging of mesh in the back, buckling, corner crushing, wall slabbing, etc.) is evident	No stress fracturing (no bagging of mesh in the back or buckling or corner crushing or wall slabbing, etc.).
Fault zones, with weak infill minerals present	Absence of low friction minerals on joints
Potential exists for formation of unstable blocks in walls or backs	No recent history of rock falls in the same drive
Ground with a history of water ingress or bolt corrosion	No visible faults, joints or cracks with potential for forming wedges
Excessive unraveling	Unraveling behavior is not excessive
Ground support problems	No history of bolt corrosion

4.4.2 Investigating Rock or Support Failures

All rock and ground support failures are to be fully investigated by the Geotechnical Engineer. As a minimum, a Preliminary Incident Report shall be completed, and entered into the Geotechnical Hazard Register. For more significant failures the Geotechnical Engineer will complete a back-analysis to determine the causes. A register of all rock and support failures will be maintained by the Geotechnical Engineer. This data will be considered when changes to the Ground Support Standards are proposed.

4.4.3 Monitoring

Where fair to poor ground conditions are encountered the Geotechnical Engineer shall determine if convergence monitoring, or other monitoring, is required. This is particularly the case for life-of-mine excavations, mine egress excavations, and larger span excavations.

Convergence monitoring is to be carried out regularly in conjunction with visual inspections of the areas. Convergence monitoring will be carried out by the Survey Department under the direction of the Geotechnical Engineer. A guideline for the frequency of inspections is presented in Table 4.2 below.

Table 4-2 Guidelines for Frequency of Convergence Monitoring

Days between Readings	Description of Areas being Monitored
1	Convergence points for the first month after installation
	Critical areas (areas around failures or new areas near development headings)
2	Convergence points for the second month after installation
4	Convergence points for the third month after installation or until long term trends are determined
7	Convergence points up to 6 months after installation to confirm long term trends
30	Long term data collection/monitoring

Responses in ground support such as cracked shotcrete or deformed bolt plates will be noted. In conjunction with this inspection, the geological structures in the area shall be reviewed. Rehabilitation will be required if deemed necessary by the Geotechnical Engineer.

An observational 'mine and monitor' risk management system will be employed at Brucejack, as part of the GCMP. Similar to the current state of practice for monitoring in underground mines in North America, Brucejack's planned ground monitoring system includes, progressively:

- Visual geotechnical inspections of mine workings;
- Tape extensometer stations;
- Survey prisms tied into the mine coordinate system;
- Vibrating wire and / or manual crackmeters;
- Multi-point borehole extensometers (MPBX) in pillars and walls;
- Borehole stressmeters; and
- Microseismic systems, as appropriate.

The various hardware systems noted above shall be augmented with an appropriate suite of software to provide near real-time visualization, displacement calculations, monitoring, and warnings for the geotechnical and operations staff of the mine. Of particular significance will be the excavations near and within the Brucejack Fault Zone, the underground crusher chamber, and crown, rib, and sill pillars.

Initially, regular visual geotechnical inspections of all mine workings shall be completed by Pretium and their contractors, and deformation monitoring of critical stope walls, pillars, and infrastructure excavations such as shops, service bays, crusher chambers, primary developments, main access ramps, ventilation infrastructure etc., shall be initiated as mining progresses. This monitoring is required to:

- Maintain safe operational practices for personnel and equipment;
- Provide warning of rock mass instability; and
- Provide geotechnical information for designs to assist in making subsequent modifications, should they be required, to achieve the desired rock mass performance.

If field observations and performance data indicate the development of un-anticipated / anomalous / elevated stress conditions, or growing uncertainties with respect to Pretium's understanding of evolving stress conditions, monitoring programs and related instrumentation will be progressively upgraded until the necessary levels of surveillance are achieved and maintained.

4.4.4 Overbreak and Blast Damage

Overbreak is to be measured by the survey department and reported on regularly. To minimize overbreak or blast damage the Superintendent and Shift Supervisor will instruct Operators on changes to the type and amount of explosives depending on changes in ground conditions and observed excavation performance. Changes in ground conditions and excavation performance are recorded during geological and geotechnical mapping by the Geology Department.

4.4.5 Historical Experience

The observations and assessments of ground behaviour and ground support reactions are used to evaluate the adequacy of the ground control management program at Brucejack. The evaluations may result in site-specific modifications for a specific working area, or a broader update to the mine design or standard ground support designs.

4.5 RECORDS MANAGEMENT

4.5.1 Geotechnical Hazards

Geotechnical Hazards shall be recorded in the Shift Boss's Log on the day the hazard is identified. The Geotechnical Engineer will also maintain a 'Geotechnical Hazard Register' in the Geotechnical Office. This Register will include a description of the geotechnical hazard, actions taken to rectify the hazard, the reporting person and confirmation that feedback on the problem was given to the reporting person.

4.5.2 Geotechnical Log Book

The Geotechnical Log Book is kept in the Mine Operations. It is a record of any inspections made of excavations and headings in mine. Any significant geotechnical milestones in an excavation's development must also be recorded in this log.

4.5.3 Mapping Data

Digital copies of all geological and geotechnical mapping are to be stored and maintained in an accessible format by the Geologist and the Geotechnical Engineer.

4.5.4 Photographic Records

Photographic records of all geological and geotechnical content are to be stored and maintained in an accessible format by the Geologist and the Geotechnical Engineer.

4.5.5 Underground Geotechnical Monitoring Data

Geotechnical monitoring data will be collected from numerous systems underground at Brucejack. These systems are described in the next chapter. All geological and geotechnical monitoring data are to be stored and maintained in an accessible format by the Geologist and the Geotechnical Engineer.

5 VERIFICATION OF THE GROUND CONTROL MANAGEMENT PLAN

This section provides a discussion of procedures and actions used to verify implementation of the GCMP. Areas discussed include Excavation Performance Assessments, Ground Support Installation QA/QC, and GCMP Review.

5.1 EXCAVATION PERFORMANCE ASSESSMENTS

5.1.1 Active Headings and Stope Inspections

During the pre-production development cycle, all active headings will be inspected by the Geotechnical Engineer at least once every three months (i.e., quarterly). When production commences, all active headings, current and in-development stopes, and related workings (drawpoints, level access drifts, cross-cuts, etc.) will be inspected and assessed by the Geotechnical Engineer on a regular basis.

Additionally, Geologists and / or Technicians who conduct ongoing geological mapping of active headings will carry out basic geotechnical inspections during the course of their work.

All underground workers shall be familiar with quality control requirements for ground support installation and performance, so that issues and concerns related to these can be identify, communicated, and resolved.

In addition to visual inspections, instrumentation such as closure stations, extensometers, stress cells, and smart cables may be installed in critical infrastructure to monitor excavation performance. These monitoring systems, used to verify successful implementation of the GCMP, are currently in development and will be described in detail in future updates to the GCMP.

5.1.2 Main Travelways and Escapeways

The Geotechnical Engineer will be required to carry out a formal inspection of main travelways and escapeways on a yearly basis. An entry must be made in the Shift Boss's Log book of this inspection. A record of this inspection must also be kept in the Geotechnical Log Book noting the time and date of the inspection, any problem areas, and actions taken to rectify them.

5.1.3 All other Excavations

A minimum requirement is that all open excavations are inspected by the Geotechnical Engineer on a yearly basis. A record of the inspection will be required to be kept in the Geotechnical drive on the computer network.

5.2 GEOTECHNICAL RISK ASSESSMENT

Broadly speaking, a risk assessment is the combined effort of: identifying and analyzing potential events that may negatively impact individuals, assets, and/or the environment; and making judgments "on the tolerability of the risk on the basis of a risk analysis" while considering influencing factors

5.2.1 Geotechnical Hazard Recognition

The recognition of geotechnical hazards before they present as ground failure is important. Integrated with mine design, ground support design, underground inspection, and ground movement monitoring when needed, ground hazard recognition involves identifying a potential hazard before it becomes an event. Through the inspection and monitoring of the existing underground openings, with analysis of the numerical modelling software and empirical method, potential hazards can be recognized in some circumstances.

5.2.2 Risk Matrix

A risk matrix is used to rate risks according to their Likelihood and Consequence. The Table 5.1 below is the risk matrix to classify identified Geotechnical hazards in terms of risk.

Table 5-1 Risk Assessment Matrix and Risk Score Legend

Impact \ Likelihood	Rare (1)	Unlikely (2)	Possible (3)	Likely (4)	Almost Certain (5)
Catastrophic (5)	Medium Risk	Medium Risk	High Risk	Critical Risk	Critical Risk
Major (4)	Low Risk	Medium Risk	High Risk	High Risk	Critical Risk
Moderate (3)	Low Risk	Medium Risk	Medium Risk	High Risk	High Risk
Minor (2)	Low Risk	Low Risk	Medium Risk	Medium Risk	Medium Risk
Insignificant (1)	Low Risk	Low Risk	Low Risk	Medium Risk	Medium Risk

Risk Score	Risk Level Category	Description
1 to 4	Low Risk	Manage by routine procedures and operations; should not require much attention but should be reviewed at least every 12 months.
5 to 10	Medium Risk	Managed by specific monitoring or response procedures; should be monitored and reviewed every 6 months.
11 to 18	High Risk	Requires escalation to VP; should be constantly monitored and reviewed every 3 months.
19 to 25	Critical Risk	Requires escalation to Board of committee responsible for risk management oversight; should be constantly monitored and reviewed monthly.

The risk matrix is designed to work in conjunction with the Geotechnical Log. The Log is designed to identify the risk, classify the risk and describer actions too minimize the risk.

5.2.3 Risk Assessment Process

Geotechnical risk assessment must be conducted by the Mine Manager or designate. Geotechnical risk assessments will be carried out for identified geotechnical hazards as frequently as required to assess the current nature of the risk. For example, if the likelihood or the consequences were to increase, the risk must be re-assessed.

Mine Manager or designate must implement all controls specified in the risk assessment.

5.2.4 Hazard Communication

Hazards must be communicated to all personnel working within the mine by appropriate means such as verbal briefings and notices on safety boards. Further, if required to or directed to by Mine Inspectors communication must be an open dialogue.

5.2.5 Hazard Prevention

The prevention of hazards is the best engineering control that can be used. Through systematic approach including geotechnical design, and verification; potential hazards can be realized and prevented. The preventive measures (controls) required vary according to the likelihood and consequence of the failure.

5.2.6 Hazard Mitigation

Hazard mitigation involves reducing the consequence of a potential failure. If a hazard can not be eliminated, operational and engineering controls must be put into place to reduce the consequence or likelihood.

Figure 5-1 Hierarchy of Controls

Elimination – The hazard can be mined out or removed from the mine site

Substitution – Modifications to be the mine design and the change of operational procedures

Isolation – The barrier off of an area to restrict access, using a variety of methods such as rope off, screen fencing, etc.

Engineering controls – Altered mine design to improve stability, such as layout, dimension, ground excavation and support plan, and increased ground inspection and monitoring.

Adminstrative – Communication of Geotechncial hazards, geotehcncial reporting and Job Hazard Analysis (JHA) for one such example.

5.2.7 Risk Register – Site Geotechnical Log

A Geotechnical Risk Register must be always kept on site. This risk register is incorporated into the Site Geotechnical Log for simplicity and efficiency. The Site Geotechnical Log will be built up over time and have a closeout process.

The closeout process illustrates that action has been taken to reduce the risk classification level.

5.3 MONITORING QUALITY ASSURANCE AND QUALITY CONTROL OF GROUND SUPPORT

Quality assurance and quality control of ground support is to be carried out through ground support installation inspections, pull testing, shotcrete batch plant inspections, shotcrete panel, core, or beam testing (ASTM C1550/ASTM C1140), and long-term monitoring.

5.3.1 Rock Bolt Installation QA/QC

5.3.1.1 Visual Inspection

Visual inspection of installed ground support will provide for the assessment of several items as listed in Table 5.2.

Table 5-2 Visual Ground Support Assessment Parameters

Parameter	Specification
Bolt position	The bolt will be installed within 200 mm of the design bolt spacing and ring spacing.
Length of bolt tail	No more than 100 mm of bolt will extend from the collar of the hole
Orientation of bolt	The bolt must be oriented to be as near as perpendicular to the surface of the excavation as possible. Bolts that are dumped forward or backwards due to poor positioning of the jumbo will be subject to replacement.
Torque nut	The torque nut will be broken to ensure the resin has set correctly
Encapsulation	Visual inspection of the collar of the bolt will be made to assess the encapsulation of the bolt. The aim is to achieve 100% encapsulation

5.3.1.2 Quality of Work

The quality of ground support installation work shall be inspected by the Shift Boss during each shift. If bolt(s) do not meet acceptable installation standards, new bolt(s) shall be installed within 250 mm of the original bolt(s).

Operators will note any bolts that do not install correctly and report this to the Shift Boss at the end of bolting the heading.

The Geologist/Geotechnical Engineer shall also visually inspect the adequacy of bolting near the heading during mapping of each new round. Any non-conformances must be reported to the Shift Boss and to the Geotechnical Engineer, Geologist or Mining Engineer.

Technical specifications and installation instructions for ground support products currently in use at Brucejack are included in Supporting Information Package I.

5.3.1.3 Pull Testing

Routine pull testing will be implemented at Brucejack with a requirement that a minimum of 0.5% of the new rock bolts installed in the current year demonstrate a pull test capacity indicating 75% of the bolt's yield strength. Additional testing of ground support in historic excavations will be carried out. For all rock bolts in a recommissioned historic excavation, selected bolts will be tested at the discretion of the geotechnical engineer to confirm the supporting efficiency. If a systemic problem, such as excessive corrosion throughout the historic excavations, is detected, a rehabilitation program will be initiated.

Testing will be conducted on rock bolts installed along the sidewalls and backs of all excavations.

In addition, some bolt pull tests will be conducted to failure. If a bolt fails to reach 75% of the yield strength, additional pull tests shall be carried out on surrounding bolts. Additional pull testing will aim to test 10% of bolts located in the five rings before and five rings after the failed bolt.

A summary of Pretium's Bolt Testing Procedures and Example Test Results are included in Supporting Information Package III.

5.3.2 Shotcrete QA/QC

In the event that shotcrete is used at Brucejack to support or remediate "Fair to Poor" ground, or for other Ground Control applications, the following QA / QC procedures will be implemented to verify adequate installation.

5.3.2.1 Batch Plant

Several quantities require monitoring during the batching stage of shotcrete production. Monitoring of these quantities is the responsibility of the Shotcrete Operator. These include:

1. The quality of the ingredients (moisture content, aggregate grading curves, etc.);
2. Cement quality;
3. Equipment calibration;
4. Shotcrete mix quality tests (temperature, unit mass, air content, maximum values of boiled absorption/maximum volume of permeable voids); and
5. Shotcrete slump testing (to be carried out once batching is complete).

5.3.2.2 During Installation

Several quantities shall be monitored during and directly after the spraying of the shotcrete. Monitoring of these quantities is the responsibility of the Shift Boss and Operators. These include:

1. Operational performance. During spraying of the shotcrete the Operator will note the ability of shotcrete to adhere to the excavation surface. Other problems such as balling of fibres (if used) or poor mix quality shall be noted by the Operator / Nozzleman. If the shotcrete mix is not suitable for spraying then the batch is to be rejected. A record of the amount of additives used during spraying, total cubic metres sprayed, and operating times shall be kept by the Nozzleman.
2. Performance during bolting. If the shotcrete breaks out during bolt installation then the Operator will stop the bolt installation. Bolting must not recommence for a 30-minute duration, to give the shotcrete further time to cure. If the shotcrete continues to break out then the Geotechnical Engineer shall be notified.
3. Thickness Checks shall be performed at regular intervals to ensure that the applied coverage meets design specifications.

5.3.2.3 Long Term Shotcrete Performance

The long-term performance of shotcrete can usually be monitored effectively with standardized, regular visual inspections. Shotcrete damage and cracking detected in areas of operational significance are to be monitored regularly. Changes in conditions must be documented and changes in crack length and aperture measured and recorded.

Other testing for long term shotcrete performance includes testing of mechanical properties. Testing of shotcrete will be carried out to determine:

1. Unconfined Compressive Strength (UCS). UCS samples shall be taken once for each heading where sprayed shotcrete by coring through shotcrete panels, or similar. Tests to determine representative UCS values at 1 day, 7 day, and 28 days shall be completed.
2. Toughness or Energy Absorption. Round Determinate Panel (RDP) tests shall be carried out as determined by BTS, depending on the type of shotcrete used (e.g., normal vs. fibrecrete) and the intended service conditions. Energy absorbed by test panels shall be equal to or greater than 360 j.

A project-specific Shotcrete QA /QC program will be developed for Brucejack in the event that significant quantities or regular use of shotcrete is required.

5.3.3 Grouting and Grout Testing

A high strength cement grout of consistent quality is required to ensure there is adequate bond between the rock bolt or cable bolt and the rock mass. The water to cement ratio to be used will depend on the type of cable bolt being installed and the grouting methods. The ratio shall be between 0.35(grout tube method) and 0.4 (breather tube method).

Uniaxial Compressive Strength and water cement ratio testing will be conducted on grout cylinders and grout bottles randomly collected during an underground grouting cycle. A minimum UCS of 30 MPa should be achieved after 28 days of curing and water cement ratio should be not more than 0.45. These tests will be performed on cable bolts installation on a random basis. However, the frequency of testing will be increased if grout strength does not meet the criteria.

5.4 REVIEWING AND UPDATING THE GROUND CONTROL MANAGEMENT PLAN

5.4.1 Annual Review of the GCMP

The GCMP is considered a "live" document that is regularly updated as ground control management approaches are changed and as knowledge of the rock mass behavior is developed.

The GCMP is reviewed annually and updated as determined by a Professional Engineer in accordance with *Mines Act* Permit M-243 Condition C.2(d). Any deficiencies identified in the annual review are addressed and included in the applicable update of the GCMP.

5.4.2 GCMP Audit

Starting in 2018, and every four years thereafter, or at the discretion of the Chief Inspector, the GCMP is audited by a third-party in accordance with *Mines Act* Permit M-243 Condition C.2(m)(ii).

5.4.3 Certification

This document was prepared, reviewed, and approved by the undersigned.

DWG TO BE READ WITH BGC REPORT TITLED "BRUCEJACK PROJECT GROUND CONTROL MANAGEMENT PLAN" DATED AUGUST 2015

Drawing 06

Structural Geology Plan Map

NOTES:
1. ALL DIMENSIONS ARE IN METRES UNLESS OTHERWISE NOTED.
2. THIS DRAWING MUST BE READ IN CONJUNCTION WITH THE REPORT TITLED "BRUCEJACK PROJECT GROUND CONTROL MANAGEMENT PLAN," AND DATED AUGUST 2015.
3. BASE TOPOGRAPHIC DATA BASED ON CONTOURS PROVIDED BY AEROGEOMETRICS, DATED FEBRUARY 2011. CONTOUR INTERVAL IS 5 m.
4. PROJECTION IS UTM ZONE 9 NAD 83.
5. GEOLOGY SOLIDS FOR THE VALLEY OF KINGS ZONE PROVIDED BY PRETIUM RESOURCES INC. ON JUNE 2, 2015.
6. GEOLOGICAL STRUCTURE AND THE ORIENTATION OF THE GRACE SHEAR ZONE WAS DIGITIZED FROM HISTORIC REPORTS AVAILABLE THROUGH MINFILE.
7. SURVEYS OF THE AS BUILT UNDERGROUND WORKINGS WERE PROVIDED BY PRETIUM RESOURCES INC. ON JUNE 22, 2015.
8. REGIONAL LINEAMENTS ARE INTERPRETED FROM A STRUCTURAL GEOLOGY REVIEW BY EARTH RESOURCE SURVEYS INC. FOR AN ADJACENT PROPERTY.
9. SYNCLINE AXIAL TRACE PROVIDED BY PRETIUM RESOURCES INC. ON THEIR MAY 1, 2012 "BRUCEJACK HIGH-GRADE TECHNICAL SESSION" PRESENTATION.
10. BRUCEJACK FAULT SURFACE TRACES PROVIDED BY SILVER STANDARD RESOURCES INC. ON MAY 21, 2010 AND DIGITIZED FROM HISTORIC NEWHAWK GOLD MINES LTD. MAPS.
11. BATHYMETRY OF BRUCEJACK LAKE RECEIVED FROM RESCAN FEBRUARY 2013.
12. UNLESS BGC AGREES OTHERWISE IN WRITING, THIS DRAWING SHALL NOT BE MODIFIED OR USED FOR ANY PURPOSE OTHER THAN THE PURPOSE FOR WHICH BGC GENERATED IT. BGC SHALL HAVE NO LIABILITY FOR ANY DAMAGES OR LOSS ARISING IN ANY WAY FROM ANY USE OR MODIFICATION OF THIS DOCUMENT NOT AUTHORIZED BY BGC. ANY USE OF OR RELIANCE UPON THIS DOCUMENT OR ITS CONTENT BY THIRD PARTIES SHALL BE AT SUCH THIRD PARTIES' SOLE RISK.

Drill Hole Summary Logs

Table 10. Brucejack Project Site Investigation Downhole Plots Unit and Lithology Key

Code	Unit Description
ARG	Argillite
JR	Jurassic conglomerate
P1	Porphyry
RHY	Rhyolite
TRS	Triassic Sediments
ANDX	Andesite

Code	Lithology Description
P1	Plagioclase-hornblende porphyritic rocks (feldspar phyric to porphyritic, lesser hornblende phenocrysts)
P2	Potassium feldsapr-hornblende-plagioclase porphyritic volcanic rocks
P3	Plagioclase porphyritic rocks
V1	Rhyolite (quartz-rich (> 15% quartz by vol) or siliceous volcanic rock)
V2	Felsic volcanic rocks (Rhyolite, Ryodacite, Dacite; silica content > 63%
V4	Intermediate volcanic rocks (Andesite, Latite; Silica content 57-63%)
V5	Trachyte (andesitic; mainly flows/sills with K-feldspar phenocrysts)
V6	Mafic dykes; cross cutting, basaltic-andesite
V8	Mafic volcanic rocks (basaltic-andesite, basalt; silica content 45-57%)
V12	Calcareous intermediate volcanic
I2	Felsic intrusive rocks
I4	Intermediate intrusive rocks
I8	Mafic intrusive rocks
M7	Metamorphosed intermediate to mafic rocks
S2	Oligomictic conglomerate
S3	Polylithic conglomerate (coarser clasts, angular to sub-angular, poorly sorted)
S4	Sandstone/arenite (fine- to coarse-grained); greywacke; carbonate rocks (limestone)
S5	Mudstone/siltstones/pelites (including calcareous); cherts and jasperites
H1	quartz vein (identified as lithology when > 100 cm)
H2	quartz-carbonate vein (massive white to white quartz and pink or white calcite, yellow sericite, ivory ankerite veining, carbonate comprised at least 5% of vein)
H3	quartz-silicate vein (quartz-tourmaline; often occurring as hard, dark-grey veinlets)
H4	quartz-sulphide vein
H6	Hydrothermal replacement (quartz veining is greater than 50% and any clasts present have been largely replaced by silica)
H7	Hydrothermal breccias (quartz veining is greater than 25%)
H8	Intensely silicified breccia zone (possible rhyolite); associated with WZ and VOK
H15	Hydrothermally altered rock
FZ	Fault Zone
NC	no core/chips
NR	not recorded
OVB	overburden

(pf) – indicates failure partially along pre-existing foliation surfaces

Summary Results of Direct Shear Failure Tests (July, 2012)

Borehole, Sample and Depth	Normal Stress (MPa)	Shear Stress (MPa)
DH-BGC12-22 (DH22-11) (206.18-206.53)	0.27	0.38
	0.53	0.54
	0.80	0.70
Residual Strength Data	1.06	0.86
	1.33	1.27
Cohesion = 74 kPa	1.59	1.49
Internal Friction Angle = 41.0º	1.86	1.80
	2.12	1.89
$r^2 = 0.986$	2.39	2.11

Sample	Normal Stress (MPa)	Shear Stress (MPa)
DH-BGC12-22 (DH22-17) (324.43-324.70)	0.45	0.38
	0.90	0.57
	1.35	0.72
Residual Strength Data	1.80	0.88
	2.25	1.01
Cohesion = 190 kPa	2.70	1.32
Internal Friction Angle = 21.7º	3.15	1.45
$r^2 = 0.988$		

Sample	Normal Stress (MPa)	Shear Stress (MPa)
DH-BGC12-23 (DH23-17) (520.77-521.04)	0.68	1.02
	1.02	1.12
	1.36	1.33
Residual Strength Data	1.70	1.54
	2.04	1.82
Cohesion = 521 kPa	2.38	1.96
Internal Friction Angle = 31.9º	2.72	2.24
	3.06	2.45
$r^2 = 0.993$		

Summary Results of Direct Shear Failure Tests (July, 2012)

Borehole, Sample and Depth	Normal Stress (MPa)	Shear Stress (MPa)
DH-BGC12-24 (DH24-06) (257.71-257.92)	0.36	0.29
	0.72	0.44
	1.08	0.59
Residual Strength Data	1.44	0.74
	1.80	0.90
Cohesion = 181 kPa	2.16	0.90
Internal Friction Angle = 20.2º	2.52	1.10
	2.88	1.25
r^2 = 0.986		

Sample	Normal Stress (MPa)	Shear Stress (MPa)
DH-BGC12-25 (DH25-13) (345.24-345.54)	0.31	0.70
	0.62	0.90
	0.93	1.05
Residual Strength Data	1.24	1.37
	1.55	1.60
Cohesion = 449 kPa	1.86	1.73
Internal Friction Angle = 35.8º	2.17	2.05
r^2 = 0.991

Appendix E

Rock Mass Characterization

GEOTECHNICAL UNITS AND LENGTH OBSERVED

- BRUCEJACK FZ (523 m)
- VOK FZ (422 m)
- WEST ZONE FZ (89 m)
- WEST ZONE WRZ (43 m)
- VOK WRZ (656 m)
- VOK D1 (191 m)
- VOK D2 (15817 m)
- VOK D3 (47264 m)
- WEST ZONE FRESH ROCK (8230 m)

NOTES:
1. QUALITATIVE DESCRIPTIONS ARE SHOWN FOR RQD (DEERE AND DEERE, 1989) AND FRACTURE INTERCEPT (ISRM, 1981).
2. BLOCKINESS INDEX IS THE SUM OF RMR '76 RATING POINTS FOR RQD AND FRACTURE INTERCEPT.
3. DATA SOURCES INCLUDE GEOTECHNICAL SITE INVESTIGATION AND EXPLORATION DRILLING PROGRAMS FROM 2010 TO 2012.
4. VOK FZ AND WEST ZONE FZ INCLUDE BRUCEJACK FZ DATA.

AS A MUTUAL PROTECTION TO OUR CLIENT, THE PUBLIC, AND OURSELVES, ALL REPORTS AND DRAWINGS ARE SUBMITTED FOR THE CONFIDENTIAL INFORMATION OF OUR CLIENT FOR A SPECIFIC PROJECT. AUTHORIZATION FOR ANY USE AND/OR PUBLICATION OF THIS REPORT OR ANY DATA, STATEMENTS, CONCLUSIONS OR ABSTRACTS FROM OR REGARDING OUR REPORTS AND DRAWINGS, THROUGH ANY FORM OF PRINT OR ELECTRONIC MEDIA, INCLUDING WITHOUT LIMITATION, POSTING OR REPRODUCTION OF SAME ON ANY WEBSITE, IS RESERVED PENDING BGC'S WRITTEN APPROVAL. IF THIS REPORT IS ISSUED IN AN ELECTRONIC FORMAT, AN ORIGINAL PAPER COPY IS ON FILE AT BGC ENGINEERING INC. AND THAT COPY IS THE PRIMARY REFERENCE WITH PRECEDENCE OVER ANY ELECTRONIC COPY OF THE DOCUMENT, OR ANY EXTRACTS FROM OUR DOCUMENTS PUBLISHED BY OTHERS.

Brucejack Fault Zone Summary

Drill hole DH-BGC12-23 (SU-318) intercepts the fault-disturbed zone from 500 m to 564 m depth, and the central fault zone from 507 m to 562 m (1104 to 1053 m elevation) (Photograph G-1 and G-2). Sericite-chlorite alteration is noted throughout the Fault Zone with a uniform intensity of 4 ("moderate") on Pretium's alteration intensity rating scale.

Photograph G-1. Core Box Photos for DH-BGC12-23 Showing Transition from Decreasing RQD Values Beginning at 500 m Depth into Fault Zone at Approximately 507 m. Bottom Three Core Boxes are Illustrative of Typical Fault Zone Core.

Photograph G-2. Core Box Photos Showing Fault-disturbed Zone and Transition into Less Fractured Rock Below Fault Zone in DH-BGC12-23 (SU-318).

Drill hole SU-082 intercepts the fault-disturbed zone between 420 m and 482 m depth and the central fault zone between 435.19 m and 463.1 m (1178 m to 1124 m elevation). Photograph G-3 shows an example of a faulted intercept. The Fault Zone in SU-082 has sericite alteration throughout with a uniform intensity of 5 ("moderate to strong") on Pretium's alteration intensity rating scale.

Photograph G-3. First 'Worst Case' Fault Discontinuity (2 mm Fault Gouge Infill) Encountered in SU-082 at 431.96 m Depth.

In DH-BGC12-23, the Fault Zone consists of intervals of competent rock with a slightly higher number of discontinuities relative to undisturbed rock mass interspersed with lengths of broken rock (RQD <30%) and a few lengths of fault gouge and decomposed rock between 10 to 150 mm thick. A 'worst case' length of fault-disturbed rock from 512.70 m to 513.85 m depth (RQD 40%) is shown in Photograph G-4.

Photograph G-4. Example of 'Worst Case' Fault-Disturbed Rock in DH-BGC12-23 (SU-318).

The more competent sections comprise 10 to 70 cm lengths of unbroken rock in which discontinuities are mainly joints with 0.5 to 5 mm aperture with no infill, calcite infill, or 1 to 2 mm of broken rock infill. A slightly altered three metre interval in DH-BGC12-23 (544.83 m to 547.58 m) exhibiting iron staining retains RQD, joint condition, and strength grade values within the characteristic range of the D2 geotechnical unit.

Point load testing in the upper portion of the Brucejack Fault Zone (from 507 to 524 m depth) in DH-BGC12-23 yielded Is_{50} values ranging from approximately 4.5 MPa to 10 MPa, which are comparable to those recorded in the 30 m interval above the fault zone. Point load test results from the lower portion of the fault zone (525 to 550 m), yield much lower values (0.1 to 0.9 MPa), then recover to 2.5 to 6 MPa at the bottom of the fault zone. No point load tests were performed below 557.5 m depth in DH-BGC12-23.

The Fault Zone is similar in SU-082, although the lengths of broken rock are absent and the discontinuities with fault gouge are from 10 to 640 mm thick. There is a length of healed fault-disturbed rock from 454 m to 457 m depth (Photograph G-7). Point load tests above the fault-disturbed zone (from 400 to 420 m depth) yielded Is_{50} values of approximately 5 MPa. Is_{50} values in the fault-disturbed zone from 420 m to 435 m dropped to 0.1 to 1.9 MPa in the fault zone, recovering to 4.8 to 8.5 MPa directly below the fault zone.

All discontinuities identified as faults with fault gouge infill, or any infill type greater than 5 mm thick are shown in SU-082 and DH-BGC12-23 downhole plots (Appendix A). 'Worst case' discontinuities in both drill holes are summarized in Table G-1 and examples of these are shown in Photograph G-5 through G-7. These photographs show short lengths of fault disturbance within mostly undisturbed rock, which is typical of the Brucejack Fault Zone.

Table G-1. Upper and Lower Boundaries of the Brucejack Fault Zone Picked from Drill Hole Data

Hole ID	Fault-disturbed zone upper boundary (m)	Fault-disturbed zone lower boundary (m)	Fault zone upper boundary (m)	Fault zone lower boundary (m)

2019 Geotechnical Data Review

BGC ENGINEERING INC.
AN APPLIED EARTH SCIENCES COMPANY
Suite 500 - 980 Howe Street, Vancouver, BC Canada V6Z 0C8
Telephone (604) 684-5900 Fax (604) 684-5909

Project Memorandum

To:	**Brucejack Gold Mine**		
Attention:	**Woo Shin, Allan Chan, Sylvia Van Zalingen**		
From:	**Catherine Schmid**	**Date:**	**March 6, 2019**
Subject:	**Review of Underground Geotechnical Units and Structural Domains for 2019 NI 43-101 Update**		
Project No.:	**1008033**		

1.0 INTRODUCTION AND SCOPE OF WORK

BGC Engineering Inc. (BGC) was requested by Pretium Resources Inc. (Pretivm) to provide technical input and serve as a 'Qualified Professional' for an ongoing update to the National Instrument (NI) 43-101-compliant Technical Report (the "NI 43-101") on its Brucejack Gold Mine (Brucejack). The NI 43-101 update will reflect a recently approved Mine Permit amendment allowing an increase in the production rate from an average of 2,700 tpd (tonnes per day) to 3,800 tpd.

The Scope of Work items detailed below are based on email and telephone communications between BGC and Pretivm on January 7, 14, and 30, 2019:

- BGC compiled all available geotechnical data collected since the project's Feasibility Study (FS) in 2013 (BGC, May 17, 2013), consisting of core logging data from exploration/infill drilling programs, geotechnical drilling programs, and hydrogeological programs, as well as underground mapping completed by others since 2013.
- The current mine geology model was reviewed by BGC to identify changes to anticipated geologic conditions, and to correlate geotechnical units and lithologies developed during the FS to the current geologic model lithologies. Some efficiency has been achieved by relying on data already compiled for a stope design update completed by BGC 2018 (BGC, 2018).
- New hydrogeological data was reviewed by BGC to re-estimate the hydrogeological conditions within the proposed mine workings, for comparison to the design assumptions of the FS.

This memo addresses updates relevant to the NI 43-101 regarding the geotechnical units and geologic structural domains previously defined for the project.

NI 43-101 report sections related to underground geotechnics will be provided by BGC under separate cover, pending issuance of the draft document by Pretivm, to consist of:

- 16.5 (Mining Methods – Geotechnical)
- 26.4.1 (Recommendations – Mining Methods – Geotechnical)
- 27.9 (References – Mining Geotechnical)

Per Pretivm's instructions, the current scope of work does not include revisions of rock mechanic designs (i.e., analysis for ground support, stope dimensions, crown pillar, etc.).

2.0 REVIEW AND COMPILATION OF AVAILABLE DATA

Pretivm provided the following data to BGC:

- Drilling program geotechnical core logging data up to February 2019 (XLS format). This dataset included all drilling programs in the Brucejack database up to drill holes SU-563, VU-920, and VUG-068.
- Underground mapping data (CSV format) compiled from Pretivm's Vulcan database in 2017 and 2018. A database export of structures logged in drill holes was also provided, however very few of the geological structures were oriented, therefore this data has not been reviewed as part of the current scope of work.
- 2017 structural geology model update (DXF format).
- 2019 geological model update (DXF format).

All of the above were developed by Pretivm and are assumed by BGC to be accurate and representative of conditions at Brucejack. Intervals with incomplete data were removed from the compilation.

The mine plan referenced in this document was provided by Pretivm on June 28, 2018 as a DXF file titled "Brucejack 2015 feasibility stopes". The structural domains referenced in this document are defined in BGC (May 17, 2013); the geographic boundaries for those domains are also provided in that report.

2.1. Review and Update of Geotechnical Units

This section presents the updated geotechnical units, including updated naming convention for the lithologies within each geotechnical unit, and updated cumulative frequency curves for the rock mass classification values (Q' (NGI, 2015), RMR (Bieniawski, 1976)) within each geotechnical unit. Due to limited additional drilling in the West Zone since the FS, only the VOK geotechnical units have been updated as part of the current scope of work.

The geotechnical units defined for the 2013 underground FS assessments were:

- West Zone:
  - WZ FZ: fault-disturbed rock
  - WZ WRZ: weathered near-surface rock
  - WZ FR: fresh rock
- VOK:
  - VOK FZ: fault-disturbed rock
  - VOK WRZ: weathered near-surface rock
  - VOK D1: ARG lithology
  - VOK D2: P1 and RHY lithology
  - VOK D3: JR, TRS, and ANDX lithology.

The 2019 geological model consists of the following units, as defined by Pretivm (pers. comm.):

- P1 Office Porphyry (OFP1): hornblende and(or) feldspar phyric latite to trachyandesite flows and subordinate fragmental rocks.
  - Correlates to the "P1" lithology used during the FS assessments.

- P1 Bridge Zone Porphyry (BZP1): hornblende feldspar phyric latite to trachyandesite flows and subordinate fragmental rocks.
    - Correlates to the “P1” lithology used during the FS assessments.
- VSF (Volcanosedimentary facies): This sequence consists of intercalated polylithic conglomerates, immature conglomerates, gritstones, sandstones, mottled submarine sandstones, through greywackes to argillites. Lateral facies variations abound. Contains common carbonate concretions (may be pyrite-, chlorite-, calcite-replaced). VSF represents the sandstone-conglomerate portion of this facies.
    - Correlates to the “TRS” lithology used during the FS assessments.
- ARG (Volcanosedimentary facies): This sequence consists of intercalated polylithic conglomerates, immature conglomerates, gritstones, sandstones, mottled submarine sandstones, through greywackes to argillites. Lateral facies variations abound. Contains common carbonate concretions (may be pyrite-, chlorite-, calcite-replaced). ARG represents the argillite portion of this facies.
    - Correlates to the “ARG” lithology used during the FS assessments.
- Volcaniclastics (CONG): immature angular to subrounded polylithic conglomerate horizon.
    - Correlates to the “JR” lithology used during the FS assessments.
- S3-Trans (Trans): Transitional unit between the CONG and the V12. Contains both blocks, bombs, and clasts.
    - This is a new unit since the FS assessments. It is a subgroup of the “JR” lithology used during the FS assessments.
- ANDX (V12): Latite fragmental unit which is heralded by a sandy reworked epiclastic base, then variably by different pyroclastic units – lapilli tuffs, crystal-lithic tuffs, crystal tuffs, agglomerates, and units with large bombs.
    - Correlates to the “ANDX” lithology used during the FS assessments.
- Silcap: Intense silica alteration along permeable horizons, typically lithology contacts and in the CONG.
    - Correlates to the “RHY” lithology used during the FS assessments.

In summary, the lithologies in the 2019 Brucejack geological model are generally consistent with the lithologies used during the FS assessments, although some of the lithology names have been revised. The most significant update to the model is the delineation of the S3-Trans lithology from the JR lithology.

Based on the updated Pretivm geological model presented above, the updated lithologies within the VOK geotechnical units are:

- VOK:
    - VOK FZ: fault-disturbed rock
    - VOK WRZ: weathered near-surface rock
    - VOK D1: ARG lithology
    - VOK D2: P1 Bridge Zone Porphyry, P1 Office Porphyry, and Silcap lithology
    - VOK D3: Volcaniclastics (CONG), VSF, S3-Trans, and ANDX lithology.

Cumulative frequency curves for the updated VOK geotechnical units are provided in Appendix A.

As shown in Figure A-1, the updated VOK D1 curve is consistent with the original FS distribution, with no significant difference noted between the RMR'76 and Q' ratings between the two datasets. The updated VOK D2 curve is also relatively consistent with the FS VOK D2 curve, with slightly lower rock mass quality in the new dataset compared to the FS dataset, with a downgrade of approximately 4 RMR'76 points, and a similar relative decrease for the Q' ratings. Importantly, overall, the data plots in the same rock mass quality classes as the FS (i.e. the median value for VOK D2 is "Good" (Bieniawski, 1976; NGI, 2015)). VOK D3 shows the most significant variation from the FS dataset, with a downgrade of approximately 10 RMR'76 points and one Q' class (i.e. downgraded from "Very Good" to "Good" (Bieniawski, 1976; NGI, 2015)). The contributing factor(s) to the decrease in observed VOK D3 rock mass quality were not assessed as part of the current scope of work, however both local rockmass quality variation (i.e. poorer rock mass quality in the areas drilled more recently compared to those drilled during the FS) and granularity within the geotechnical logging data (i.e. faults or poor rock mass quality not identified as separate small intervals, and instead logged as part of a larger (and subsequently weaker) interval) are potential factors.

2.2. Review of Structural Domains

Pretivm's Vulcan compilation of 2017 and 2018 underground structural geology mapping data was used to generate stereonets for defined structural domains VOK 1 and VOK 2 (Appendix B). No geologic structures were mapped in VOK 3, and only 52 structures were mapped in the West Zone, therefore these domains are not considered in the current update. The mapping data were assigned to "ore zone" and "wall rock" groupings by filtering structures inside and outside the proposed stopes, respectively. The structure type within the new dataset consists primarily of 'faults'.

Updated stereonets were checked for consistency with the FS structural domain stereonets, and are summarized below:

- VOK 1 Wall Rock – This domain generally shows consistency with the FS design stereonet, except for the SE striking sets, which were observed to be moderately (30 to 60°) dipping in the FS data and appear to be steeply (65 to 85°) dipping in the most recent mapping data (with the moderately dipping set apparent in the FS data not present). This may be due to spatial variation in the orientation of the set, with the 2017 and 2018 data predominantly from the upper levels of the mine, and the FS data from drill holes located throughout the mining footprint; or it may be a new set. Because both the moderately dipping and steeply dipping NE striking sets were observed in this domain in 2017 (BGC, 2018), and the steeply dipping set is present in other domains, it's considered more likely that this steeply dipping set is an additional set not previously identified in the FS assessments. The northwest striking shallowly dipping (20 to 35°) set identified in the FS assessments is weak to absent in the most recent data.

- VOK 1 Ore Zone – The number of poles within the most recent mapping data for the VOK 1 Ore Zone domain is small (two poles), and therefore statistically not significant enough for a comparison to the historical data.
- VOK 2 Wall Rock – The VOK 2 Wall Rock domain is consistent with the FS design stereonet. A moderately (40 to 50°) dipping SE striking set is present in the most recent mapping data and was not as strongly developed in the FS data but is weakly developed relative to the subvertical SW striking set, which is the dominant set in this domain.
- VOK 2 Ore Zone – The VOK 2 Ore Zone domain is generally consistent with the FS design stereonet, except for a lack of moderately-dipping structures in the most recent data. These moderately dipping structures were identified in the FS assessments as weak sets relative to the dominant steeply-dipping to subvertical southeast striking set, which continues to be the dominant set as shown in Appendix B. This dominant set also appears to overturn occasionally in the most recent data.

2.3. Review of Major Structures Model

The 2017 three-dimensional major structures (fault) model developed by Pretivm includes the Brucejack Fault, the Rainy Fault, the VOK Main Fault, and the Upper Thrust Fault. At the time of the FS (BGC, May 17, 2013), only the Brucejack Fault had been modelled in three-dimensions, hence it was the only major structure considered during assessment of the potential influence of large-scale structure on the proposed FS mine plan.

The three additions to the major structures model since the FS appear to be part of a package of gently dipping south-southwest striking structures, as there is a periodicity to the Rainy Fault, VOK Main Fault, and Upper Thrust Fault. A geotechnical summary of the structures and the potential for them to affect excavation stability is presented below:

- The Rainy Fault is a gently dipping (10 to 30 deg.) south-southwest striking (220 to 240 deg.) fault (Figure 1). It was studied in detail as part of the geotechnical assessment for the underground crusher (BGC, November 6, 2015). The fault has a thickness ranging between 0.5 – 15 meters (average thickness: 2 m), with the thickness appearing to increase with depth. The rock mass within the fault zone is generally very blocky with very poor to poor RQD (< 50%) and discontinuity spacing less than 0.20 m but varies from relatively unbroken rock to compact silty/clayey gouge zones up to 1.5 m thick. Often the fault zone is comprised of multiple gouge zones separated by more competent zones of very blocky rock mass. Seepage conditions within the zone vary significantly, from dry to dripping. The Rainy Fault intersects several levels of the mine, including the VOK main access ramp, 1340 to 1310 elevations of the north ventilation raise, and stoping areas between 1205 to 1355 elevation. It has been intersected by mine development to date, and although seepage is strong and rock mass quality decreases within the fault zone, Pretivm has successfully mined through the fault zone using increased ground support. The seepage is reported by Pretivm to decrease over time to an essentially dry condition.

Figure 1. Visible exposure of the Rainy Fault near DH-BGC15-02 drill station. Red line indicates hangingwall of fault.

- The VOK Main Fault intersects the upper levels of the mine within the stoping areas between the 1415 and 1475 levels. This fault strikes perpendicular to the stope hangingwalls in this area and has the potential to cause structural instability in the stope hangingwalls and backs. This fault was intercepted during the FS drilling program by drill hole DH-BGC12-23 at between approximately 210 to 250 m along hole and resulted in locally reduced RQD (between 40 to 80%) and fracture spacing (between 0.06 to 0.50 m) compared to the fresh (unfaulted) rock. It has been intersected by mine development to date on the 1470 and 1440 elevations.
- The Upper Thrust Fault is highest in the stratigraphic sequence of the three known faults in this package and intersects a small number of planned stopes between the 1450 and 1520 Levels at the southwest corner of the mine. It has not been intersected by mine development to date. It strikes subparallel to a development drift on the 1480 level and has the potential to cause structural instability and resulting increased ground support requirements during development through that area. DH-BGC12-23 also intercepted this fault, and although a small fault structure was logged, it did not cause a significant reduction in rock mass quality.

2.4. Review of Hydrogeological Data

Hydrogeological conditions, including bedrock hydraulic conductivity estimates, hydraulic conductivity variation with depth, and groundwater elevations at Brucejack were summarized in the FS assessments (BGC, May 17, 2013). Since then, BGC has completed a groundwater monitoring well installation in 2018 (BGC, February 21, 2019), as well as annual groundwater monitoring reports for 2015, 2016, and 2017 (BGC, March 30, 2016; March 27, 2017; March 19, 2018). New data was collected, and groundwater quantity assessments were completed as part of those studies, using hydraulic head data from monitoring wells and monthly average underground mine dewatering rates. The rock mechanics assessments used to support the mine

design and planning generally assume that the rockmass is dewatered by ongoing mine dewatering activities. This assumption remains valid based on the new information.

Anecdotally, stopes and development within the Brucejack Fault and other major structures may encounter more groundwater inflow than the average mine inflows quantified to date (BGC, February 21, 2019), based on groundwater inflow reported by Pretivm during drilling of several exploration drill holes that intersected the Brucejack Fault. However, existing hydrogeological data (packer testing and hydraulic head measurements) do not confidently identify the Brucejack Fault as a groundwater flow path or flow barrier. While ongoing mine dewatering activities may be able to dewater this structure, additional hydrogeological characterization of the major structures including the Brucejack Fault, and subsequent update of the existing numerical groundwater flow model, would increase operational confidence in managing inflow from major structures.

3.0 COMPARISON TO FEASIBILITY STUDY DESIGN ASSUMPTIONS

This section summarizes the comparison of the most recent geotechnical and structural data to the data used for the FS rock mechanics assessments.

The geotechnical units used for the FS assessments had slightly higher assumed median rock mass quality when compared to the most recent data collected at Brucejack, although overall the median rock mass quality for all three VOK geotechnical units remains “Good” (Bieniawski, 1976; NGI, 2015). This moderate reduction in apparent rock mass quality has the potential to be most significant for stope stability, where maximum achievable stope dimension is strongly correlated to rock mass quality. The updated stope designs presented in BGC (2018) assumed two rock mass classes at Brucejack – Q’ of 10 to 50, and Q’ of 3 to 10. These classes, and the resulting stope design recommendations, were intended to demonstrate the potential variability in rock mass quality and resultant achievable stope spans at Brucejack. Although the median values of the new data suggest these ranges are still valid (with 50% of the rock mass having Q’ >10), the medians are close to the threshold value, and the upper range (i.e., higher quality rock) may be less common than initially assumed during previous assessments. BGC continues to recommend that Brucejack review stope designs on a case-by-case / package-by-package basis, particularly if optimized, larger, and less conservative stope dimensions (i.e. greater than “median” designs) are proposed to be implemented in the mine plan.

The structural domains used for the FS assessments are generally consistent with the most recent data collected by Pretivm. The most significant change is the appearance of a moderately-dipping set in VOK 2 Wall Rock domain, which has the potential to form wedges with other moderately-dipping structures and result in structural instability, particularly if the structures are persistent and closely spaced. Despite this new set, the FS ground support designs (BGC, 2013) and updated stope designs (BGC, 2018) are considered by BGC to be suitable for the “base-case designs” at Brucejack because there appears to be a low concentration of adversely oriented conjugate sets with which this set could form wedges. However, due to adverse orientation of the discontinuity sets in the Brucejack rock mass, there will remain residual risk for rock fall and stope dilution. The risk increases where the discontinuities are persistent and closely spaced, and as stope

dimensions increase. The existing geotechnical database is insufficient to predict where more persistent and/or closely spaced discontinuities may occur, therefore thorough and regular geotechnical inspections and cavity monitor surveys throughout the development and production continue to be recommended.

There are three newly-identified major structures (fault zones) identified within the mining footprint, in addition to the Brucejack Fault. These new structures were not considered in the rock mechanics assessments for the FS mine design. The mine design (i.e., excavation dimensions, ground support designs, and sequencing) should be reviewed on a case-by-case basis in all areas where these major structures are within 20 m of the proposed excavations, with consideration to the interpreted rock mass quality, geologic structure, groundwater conditions, stress, and mine sequence local to the area of interest.

4.0 CLOSURE

Dear Lyle,

Re: Brucejack Project - Review and Update of Stope Designs – FINAL

Pretium Resources Inc. (Pretium) requested that BGC Engineering Inc. (BGC) review and update the mining geotechnics and stopes designs included in the Brucejack Project's (Brucejack) Feasibility Study (FS) (BGC, 2013). The current work is carried out per Pretium PO 1024802.

The scope of work for the mining geotechnics and stope designs update includes:

- A review of Pretium's current geotechnical model, mine-scale fault model, and underground drilling and mapping data collected since 2013.
- A review and update of the FS geotechnical units and structural domains.
- A review and update of the FS stope stability assessments, using empirical methods and preliminary numerical modelling.
- Determination of ground support recommendations for enlarged stopes.
- A summary memo including updated stope designs and related geotechnical guidance.

BGC did not complete a site visit as part of the work; geotechnical conditions and related design inputs used in the following analyses require field confirmation.

1.0 SUMMARY OF FS GEOTECHNICS AND STOPE DESIGNS

For the FS, BGC developed design recommendations for stope backs and walls using the empirical "Stability Graph" method (Hutchinson and Diederichs, 1996, and Nickson, 1992, after Potvin et al., 1988).

Geotechnical and stope geometry parameters are combined to determine a "Stability Number" (N'), defined by:

$$N' = Q' \times A \times B \times C$$

Where:

Q' is a rock mass classification parameter

A is a measure of the ratio of intact rock strength to applied stress

B is a measure of the relative orientation of dominant structure with respect to the excavation surface

C is a measure of the influence of gravity on the stability of the face being considered.

Conservative and base case Q' values of 10 and 40 respectively were used in combination with conservative A, B, and C inputs to calculate permissible stoping dimensions (hydraulic radii).

Statistical observations of the Brucejack dataset indicated that regardless of lithology, alteration, geological domain, or geotechnical unit, less than 20% of mapped or logged data had a Q' value less than 10, and greater than 50% of the rock had a Q' value of 40 or more.

Stability Graph inputs used in the FS are summarized in Table 1, below. The resulting FS stope designs are summarized in Table 2.

Table 1. Stability Graph Assumptions For FS Stope Designs

Parameter	Value in FS	FS Design Assumption
Q' (base case)	40 (all fresh rock)	Median
Q' (conservative case)	10 (all fresh rock)	Lower quartile
A	0.12 (back) 1.0 (walls)	Assume induced stresses concentrate above & adjacent to backs; Walls are generally destressed.
B	0.2 (back, walls)	Conservative assumption based on structural variability in all domains
C	2 (backs) 8 (walls)	Defined based on critical discontinuity set assuming horizontal structure in back and vertical structure in walls.

Table 2. FS Stope Design Summary

Stope Face	N' (conservative)	N' (base case)	Unsupported Hydraulic Radius (conservative)	Unsupported Hydraulic Radius (base case)
Back	0.5	2.0	1.9	3.1
Hangingwall	16.0	64.0	6.2	11.0

Pretium mine planners used these criteria to determine mining shapes for the FS, primarily resulting in transverse stopes 30 m high, 15 m wide (parallel to mineralization strike), and 20 m deep (ore width).

2.0 REVIEW AND UPDATE OF STOPE DESIGNS

This section summarizes recent data and related revisions to the geotechnical units and structural domains, revised stability graph inputs, and resulting updated empirical stope designs. Preliminary numerical modelling was completed to further investigate and confirm the results of the empirical assessment, and those results are also summarized below.

2.1. New Data

Pretium provided the following data for the design updates, which became available after the FS stope designs were completed:

- 2016 underground exploration drilling program core logging data (drill hole collars VU-409 to VU-752) (XLS format)
- 2017 geological model update (DXF format)
- 2017 structural model update (DXF format)
- All available underground mapping data (DXF and CSV format)
- Multi-point borehole extensometer (MPBX) readings from 1350-16, 1350-20, and 1350-28 (XLS format)
- October 2017 mine as-built (DXF format)
- 2017 mine development plan (DXF format)

All of the above data were developed by Pretium. Pretium also verbally reported to BGC that all five stopes developed to date (all within the upper mining levels) had been performing adequately.

2.2. Revised Geotechnical Units and Structural Domains

Geotechnical core logging data from the 2016 underground drilling program was converted by BGC into Q' values using the industry-standard equation:

$$Q' = e^{(RMR_{76}-44)/9}$$

Per the FS, lithology was used as a basis to sort this data into geotechnical units (VOK-D1, -D2, -D3, -FZ). Updated cumulative frequency graphs including the FS and 2016 data are presented in Appendix A. Faulted rock is not included in the current assessment, as stope designs within large fault zones require detailed assessment on a case-by-case basis.

From analyses of this data, Geotechnical Unit 1 and Geotechnical Unit 2 have been updated from the FS, as follows:

- Geotechnical Unit 1: 10 < Q' < 50 ("average" rock mass)
- Geotechnical Unit 2: 3 < Q' < 10 ("poor" rock mass)

Recent geologic mapping data provided by Pretium has been used to update design stereonets for structural domains VOK 1 and VOK 2. No geologic structures were mapped in VOK 3. The design discontinuity sets were ranked according to pole concentrations and association with major structures to define the critical discontinuity sets for design. Updated design stereonets for VOK 1 and VOK 2 are presented in Appendix A. Design stereonets for VOK 3 and the WZ, where no new data was collected, are available in the FS report (BGC, 2013).

2.3. Stope Design Update

The revised geotechnical units and structural domains were used to update the inputs to the Stability Graph method, as summarized in Table 3. The resulting permissible stope designs, presented as unsupported and supported cases for a given rock mass quality range, allow Pretium flexibility in their stope designs relative to rock mass quality and operational considerations such as ore geometry and ease of support (cable bolt) installation. Based on a review of the mine plan provided by Pretium, it has been assumed that the base-case stope orientation is a transverse stope orientation with a hangingwall orientation of approximately 140/80 (dip direction/dip).

Table 3. Stability Graph Assumptions For Current Work

Parameter	Value	Design Assumption
Q’	10 – 50	Geotechnical Unit 1
Q’	3 - 10	Geotechnical Unit 2
A	0.1 (back) 1.0 (walls)	Assume induced stress concentrates in back and that the walls are destressed.
B	0.3 (walls) 0.6 (back)	Based on weighted average structural variability in all domains
C	2 (backs) 4 (walls)	Defined based on critical discontinuity set assuming horizontal structure in back and adversely oriented sliding structure in walls.

The resulting Stability Graphs and stope dimension design tables for Domain 1 and Domain 2 are presented in Appendix B. The FS designs were derived based on lower quartile rock mass quality assumptions. The design recommendations presented in this report assume median rock mass quality, and that the more common geologic structures associated with large-scale faults and shears are more likely to cause stope instability. The updated designs suggest:

- Unsupported stope heights of up to 60 m may be achievable, dependent on rock mass quality as shown in Appendix B, and on the presence of persistent and closely spaced adversely-oriented discontinuities. The risk of rock fall and stope dilution increases as stope height increases. Therefore, at 60 m stope heights, Pretium should anticipate a requirement for cable-bolting of the hangingwalls and end walls to mitigate structurally-

controlled failures, where accessible and practical (i.e. on 30 m sublevels, for instance). Paste stability at these dimensions has not been assessed for this study.

  - According to feedback from Pretium, stope heights exceeding 30 m may not be practicable due to existing mine development.

- Achievable stope widths and lengths will be largely governed by the stability of the stope backs. The design cases presented in Appendix B indicate unsupported stope widths or lengths of 20 m may be achievable, with increased lengths in one dimension achievable with a reduction in the other.
  - According to feedback from Pretium, stope widths must be a factor of 15 m (i.e. 15 m or 30 m) due to existing mine development. Therefore, an increase in stope width may not be practicable. It has therefore been assumed the stope length will be increased preferentially over stope width. If stope width is 15 m, stope lengths of 40 to 45 m may be achievable in the upper range of Geotechnical Unit 1 (i.e. rock approaching a Q' value of 50).
- Ground support requirements will depend on the stope dimensions and rock mass quality in the production areas. For ground support costing purposes, for a 'base case' stope 30 m x 15 m x 40 m (height x width x length), it can be reasonably assumed that approximately 10% of exposed walls and backs will likely require a minimum cablebolt density of ~0.25 bolts/m^2 in the hangingwall, and ~0.30 bolts/m^2 in the back. This estimate is based on the cumulative frequency charts provided in Appendix A, and will vary based on rock mass conditions in individual stopes.

Modifications to the FS designs outlined in this report provide additional flexibility in the stope designs, despite minimal observed change in the rock mass and geologic structure dataset; BGC notes that the improvements largely result from a reduction in the degree of conservatism necessarily applied to the designs at the time of the FS. Pretium should consider the above designs preliminary until the currently deployed 'mine and monitor' approach confirms the soundness of the designs. Recommendations to mitigate the increased risk are discussed in Section 3.

2.4. Preliminary Numerical Modelling Results

The results of the stope stability assessment were used to inform preliminary numerical modelling, with the objective of understanding the potential implications of the larger stope dimensions on overall mine stability (i.e. sill and rib pillar stability, effects on stability of nearby development, etc.). The reliability of the numerical models is limited due to a limited understanding of the in-situ stress conditions, and a limited amount of calibration data. However, they do support the empirical analyses for stope lengths up to 40 m, and do not indicate significant loss of ground control at stope lengths of 45 m. A summary of the model inputs, geometry, and results are presented in Appendix C, and include some runs to investigate the effect of lower rock quality and deeper stress conditions (400 m) on rock mass stability.

3.0 CONCLUSIONS AND RECOMMENDATIONS

BGC's analysis indicates that Brucejack's 'base case' stope design dimensions could be moderately increased from those reported in the FS report (BGC, 2013). However, the following items were noted by BGC:

- Due to adverse orientation of the discontinuity sets in the Brucejack rock mass, there will remain residual risk for rock fall and stope dilution. The risk increases where the discontinuities are persistent and closely spaced, and as stope dimensions increase. The existing geotechnical database is insufficient to predict where more persistent and/or closely spaced discontinuities may occur, therefore thorough geotechnical inspections and cavity monitor surveys throughout the development and production continue to be recommended.
- A revised "base case" stope design of 30 m height x 15 m width x 40 to 45 m length is supported by empirical analyses and preliminary numerical modelling, for rock in the upper range of Geotechnical Unit 1 (i.e. rock approaching a Q' value of 50) in dry conditions under moderate stress. BGC recommends that Pretium consider using this revised "base case" on a case by case basis with consideration to the interpreted rock mass quality, geologic structure, groundwater conditions, stress, and mine sequence local to the stope of interest.
- Where poorer quality rock masses and/or persistent structure(s) are encountered, customized support designs which address local conditions are required.
- Increasing the stope heights may affect not only the rock mass stability but the adjacent paste backfill stability. The stability of the paste backfill has not been assessed as part of the current study.
- Underground mining personnel will need to assess and confirm that rock mass conditions closely match the assumed conditions. Should different or atypical conditions be encountered, the designs supplied herein may not be appropriate or valid.
- The designs are valid for fresh rock only, and should not be used for stope design in weathered (near-surface) or faulted rock.
- Pretium should consider the above designs preliminary until the currently deployed mine and monitor approach confirms the robustness of the designs.

WZ FR	126	7.0	18	116	5.7	21	27.3	35.0	0.17

Notes:
1. Design UCS values have been estimated from the median Is50 values using laboratory-derived K values if available
2. Unit weights are based on average results of specific gravity testing if available
3. Hoek-Brown material constants have been derived based on a review of laboratory testing results
4. Young's Modulus and Poisson's ratio have been estimated based on laboratory testing results if available

Table 3.2-5. Rock Mass Strength and Deformation Modules

Unit	UCS (MPa)	GSI[2]	Unit Weight[3] (kN/m³)	m_i	m_b	S	E_{rm} (GPa)
VOK FZ	89	60	26.3	12	1.110	0.0023	5.13
VOK WRZ	50	63	28.6	17	1.879	0.0037	0.77
VOK D1	116	72	27.2	17	3.211	0.0144	9.76
VOK D2	95	70	27.1	19	3.186	0.0106	9.02
VOK D3	73	85	27.3	26	10.647	0.103	14.37
WZ FZ	77	57	26.3	12	0.928	0.0015	4.27
WZ WRZ	37	62	28.6	17	1.771	0.0032	0.73
WZ FR	116	85	27.3	21	8.599	0.103	16.77

Notes:
1. The Hoek-Brown failure criteria have been estimated assuming a disturbance factor ('D') of 0.8 for all units.
2. GSI is calculated from median rock mass parameters for each unit, where GSI = RMR '76.
3. Unit weights are based on average results of specific gravity testing when possible.
4. The Hoek-Brown curves have been derived using a sigma3 max. for a tunnel depth of 650 m.

Lyle Morgenthaler, P.Eng.
Chief Mining Engineer
Brucejack Gold Mine
Pretium Resources Inc.
2300 – 1055 Dunsmuir Street
Vancouver, BC, V7X 1L4
Canada

Dear Mr. Morgenthaler,

Re: Brucejack Gold Mine 2019 Annual Review of the Underground Workings

This letter has been prepared by SRK Consulting (Canada) Inc. (SRK) at Pretium Resources Inc.'s (Pretivm's) request to address the requirement under Permit M-243 Condition C.2(m)(i) for an annual review of the underground workings by a Professional Engineer. The letter is to satisfy the 2019 reporting requirements of that condition, for submission to the Chief Inspector of Mines.

Pretivm retained SRK Consulting (Canada) Inc. (SRK) in February 2019 to conduct the work required for the annual review. Work conducted by SRK in support of this 2019 annual review included:

1. Review of existing underground mine design and related ground control documentation, including the updated minimum ground support standards approved in January 2020; the Ground Control Management Plan (GCMP) and its included Standard Operating Procedures (SOPs), structural geology models, rock mass data and historical design reports prepared by BGC Engineering and others.
2. Site based underground workings review, which was initiated Tuesday September 24th, 2019 with a site visit by Tim Coleman, PEng, BEng (Hons) ACSM MSc DIC and Bruce Murphy, PEng, MSc., and concluded with a follow-up site visit by SRK's consultant, Alida Hartzenberg, M.Sc., February 15th to 20th 2020.

The February 2020 detailed site visit included attendance at planning, safety and daily production meetings to gain a better understanding of the mining operations. Discussions were held with various personnel involved with underground mine planning and implementation, including those from the Technical Services (including Geotechnical), Geological, and Mining departments and personnel with the underground mining Contractor (Procon). These discussions were targeted at gaining an understanding

of the interaction between the different disciplines and their integration in the operations. The underground visits were predominantly led by Brucejack's Senior Geotechnical Engineers and Junior Geotechnical Engineers, accompanied by other technical personnel.

SRK has completed its 2019 review of the underground workings and procedures and in general practices were considered to be good. SRK has provided feedback to Brucejack Gold Mine's technical and engineering teams with some suggested areas of improvement, as follows:

- Formal reporting and follow-ups of requests should be completed to ensure close-outs;
- Update and sign off on the secondary support recommendations and communicate these to relevant teams;
- Ensure all intersections are supported by means of long support, as per the minimum ground support standard;
- Where different lengths of the same ground support type are used across the mine, a means of identifying the difference in length after installation should be implemented;
- Consideration should be given to modifying the ground support in the overcut to reduce the likelihood of instabilities, typically observed as overbreak/damage in stope shoulders, resulting from mining of primary stopes, which have the potential to adversely impact the safe extraction of secondary stopes;
- Ensure quality assurance and quality control of all support products used at the mine is being undertaken and documented;
- Review and update the monitoring and instrumentation procedures;
- Reconciliation of Stope Performance; and
- Minimum ground control designs are recommended for the major structures and associated alteration. This would not preclude the current approach of site-specific assessment but sets guidelines to ensure consistency of approach to the implementation of ground support at the mine.

Sincerely,
SRK Consulting (Canada) Inc.

Tim Coleman, PEng, BEng (Hons) ACSM MSc DIC
Principal Consultant, Mining Rock Mechanics

Alida Hartzenberg, MSc
Consultant, Mining Rock Mechanics

Disclaimer—SRK Consulting (Canada) Inc. has prepared this document for Pretium Resources Inc.. In no circumstance does SRK accept any consequential liability arising from commercial decisions or actions resulting from the use of this report by a third party.

The opinions expressed in this report have been based on the information available to SRK at the time of preparation. SRK has exercised all due care in reviewing information supplied by others for use on this project. Whilst SRK has compared key supplied data with expected values, the accuracy of the results and conclusions from the review are entirely reliant on the accuracy and completeness of the supplied data. SRK does not accept responsibility for any errors or omissions in the supplied information, except to the extent that SRK was hired to verify the data.

Appendix L

Minimum Ground Support Standards

Table 1 Minimum Primary Ground Support– Drift

Rock mass Condition	Dimension (m x m)	Ground Support Type	Length (m)	Spacing (m x m)	Additional comment
Level development (access drift, level drift, remuck and refuge station drive)					
Good to Fair (RMR_{76} > 40)	5.5w x 5.5h	**#7 fully grouted rebar** plus #8 welded wire screen to cover the back and walls with not more than 2.5m from sill.	2.4	1.8 x 1.8	
Poor to very poor (RMR_{76} < 40)			2.4	1.2 x 1.2	Special instruction might be required from geotechnical engineer. Screen is to bring down to 1.5m from sill.
Main ramp (decline, incline and other hauling routs)					
Good to Fair (RMR_{76} > 40)	6.0w x 5.5h	**#7 fully grouted rebar** plus #8 welded wire screen to cover the back and walls with not more than 1.5m from sill.	2.4	1.8 x 1.8	
Poor to very poor (RMR_{76} < 40)			2.4	1.2 x 1.2	Special instruction might be required from geotechnical engineer
Cross cut (waste cross cut)					
Good to Fair (RMR_{76} > 40)	5.0w x 5.0h	**#7 fully grouted rebar** plus #8 welded wire screen to cover the back and walls with not more than 3.0m from sill.	2.4	1.8 x 1.8	
Poor to very poor (RMR_{76} < 40)			2.4	1.2 x 1.2	Special instruction might be required from geotechnical engineer. Screen is to bring down to 1.5m from sill.
Cross cut (Ore cross cut)					
Good to Fair (RMR_{76} > 40)	5.0w x 5.0h	**2.1m Splitset** plus #8 welded wire screen to cover the back and walls with not more than 3.0m from sill.	2.1	1.2 x 1.2	
Poor to very poor			2.1	1.2 x 1.2	Special instruction might be required from geotechnical engineer. Screen is to bring down to 1.5m from sill.
Develop through paste backfill					
11% binder paste backfill	5.2w x 5.3h	2.1m long splitset plus #8 welded wire screen plus two 50mm thick layers of shotcrete (total thick of 100 mm): one before bolt & screen and another after bolt & screen.	2.1	1.0 x 1.0	Development sequence: 1). 2m excavation; 2). 50 mm thick of shotcrete will be applied right after excavation; 3). 6 hours shotcrete curing; bolt and screen; excavation for next round; 4). apply 50mm thick shotcrete to the current round exposed paste and to second layer to the previous round to cover the bolt and screen. Repeat the steps until paste development completion.

Note: 0.9m long splitset will be used to tight the screen to the rock surface whenever required.

Table 2 Secondary Ground Support - Drift

Rock mass Condition	Dimension (m x m)	Ground Support Type	Length (m)	Spacing (m x m)	Additional comment
Top cut of ore stope (Primary stope)					
Good to Fair (RMR_{76} > 40)	5.0~15.0w x 5.0h	single strand cable bolts	6	2.5 x 2.5	
Poor to very poor (RMR_{76} < 40)		single strand cable bolts	6	2.0 x 2.0	Special instruction might be required from geotechnical engineer
Top cut of ore stope (Secondary stope)					
Good to Fair (RMR_{76} > 40)	5.0w x 5.0h	double strands cable bolts	12.5	1.5 x 1.5	Toes fan out
Poor to very poor (RMR_{76} < 40)		double strands cable bolts	12.5	1.5 x 1.5	Special instruction might be required from geotechnical engineer
Bottom cut of ore stope (full width expansion for mucking only)					
Good to Fair (RMR_{76} > 40)	5.0w x 5.0h	Connectable Super Swellex	4.88	2.5 x 2.5	Three Superswellex per ring in the back to be installed before slash. No long support for the slashed area.
Poor to very poor (RMR_{76} < 40)		Connectable Super Swellex	4.88	2.0 x 2.0	Three Superswellex per ring to be installed before slash. Special instruction might also be required from geotechnical engineer.

Bottom cut of ore stope (full width expansion for drilling)					
Good to Fair (RMR_{76} > 40)	15.0w x 5.0h	Connectable Super Swellex	4.88	2.5 x 2.5	Three Superswellex per ring to be installed at vertical before slash . Slashed area will have the rest of the Superswellex installed into the pattern.
Poor to very poor (RMR_{76} < 40)		Connectable Super Swellex	4.88	2.0 x 2.0	Special instruction might be required from geotechnical engineer

Table 3 Secondary Ground Support guideline for Oversized Intersections

Rock mass Condition	Dimension (D, m)	Ground Support Type	Length (m)	Spacing (m x m)	Additional comment
Small scale, 3-way intersection					
Good to Fair (RMR_{76} > 40)	7~10	6 or more single strand bulbed cable bolt	6	2.5 x 2.5	
Poor to very poor (RMR_{76} < 40)		9 or more single strand bulbed cable bolt	6	2.0 x 2.0	Special instruction might be required from geotechnical engineer
Large scale, 4-way intersection					
Good to Fair (RMR_{76} > 40)	>10	9 or more single strand bulbed cable bolt	6	2.5 x 2.5	
Poor to very poor (RMR_{76} < 40)		12 or more single strand bulbed cable bolt	6	2.0 x 2.0	Special instruction might be required from geotechnical engineer
Intersection in temporary drift					
Good to Fair (RMR_{76} > 40)	7~9	6 or more connectable Superswellex	2.4	2.5 x 2.5	
Poor to very poor (RMR_{76} < 40)		9 or more connectable Superswellex	2.4	2.0 x 2.0	Special instruction might be required from geotechnical engineer

Project Memorandum

To:	**Pretium Resources Inc.**	**Doc. No.:**	**BJ-2017-55**
Attention:	**Woo Shin, Allan Chan, George Zazzi**	**cc:**	**Roland Tosney**
From:	**Cathy Schmid**	**Date:**	**September 22, 2017**
Subject:	**Brucejack Project – Full Width Undercuts Ground Support Design Review – DRAFT**		
Project No.:	**1008026**		

1.0 BACKGROUND AND SCOPE

Pretium Resources Inc. (Pretium) requested (via email on September 11, 2017 and September 13, 2017) that BGC Engineering Inc. (BGC) review and update the ground support standard for 15 m wide full width undercuts for the Brucejack Project underground mine (Brucejack). The scope of work for this request includes:

1. Review of the existing ground support design for the 15 m wide full width undercuts (Split-set, 2.4 m length, 1.8 x 1.8 m spacing in the back and walls; Bulbed single cables, 6 m length, 2.5 x 2.5 m spacing in the back; 25% shotcrete coverage (back)) to assess the feasibility of achieving the design objectives using 4.88 m (16') connectable Super Swellex (PM24C) instead of the single cables.
2. Update the existing analyses (BGC 2013; BGC 2017) assuming no change to the geotechnical properties for the rock mass and geologic structure used in those analyses.
3. Summarize all analysis work in a brief memo. The memo will be issued in draft to Pretium for review, and then issued in final upon receipt of edits from Pretium.

The objective of this assessment is to confirm if Pretium can replace single strand cable bolts (i.e., the long support) for the full width undercuts with 4.88 m (16') connectable Super Swellex (PM24C) for the "average" and "poor" rock mass conditions. This scope does not include update of the ground support standard drawings or Ground Control Management Plan (GCMP), or site visits to confirm the suitability of the designs. This memorandum summarizes the current work defined under numbers 1 and 2 above, and the resulting updated ground support designs.

The revised designs supersede the designs presented in the current GCMP (2016) and a recent ground support desktop review of the ore drifts and cable bolt ground support standards (BGC 2017), and should be incorporated into the 2017 GCMP version when it is updated by Pretium before the end of the current year.

2.0 DESIGN METHODOLOGY AND CURRENT STANDARD GROUND SUPPORT

2.1. Current Standard Ground Support Designs in Ore Drifts

The full width undercuts are developed as part of stope development work. They are developed as a pilot drift that is then slashed out to full 15 m width as the bottom sill of the stope (Figure 1). The stope is drilled, blasted, and mucked, and then backfilled.

Figure 1. Schematic plan and cross-section view of full width undercut development (base images from Pretium (2014))

The full width undercut ground support designs currently used at Brucejack are:

- "Average" rock mass (10 < Q' < 40) (GSI 70 – 85)
  - SS39 Split Sets, 2.4 m (8') length, 1.8 m spacing
  - Single strand cable bolts, 6 m length, 2.5 m spacing
  - #9 welded wire mesh on the back and 1.0 m down the walls
- "Poor" rock mass rock mass (0.1 < Q' < 10) (GSI 50 – 70)
  - SS39 Split Sets, 2.4 m (8') length, 1.8 m spacing
  - Single strand cable bolts, 6 m length, 2.5 m spacing

- #9 welded wire mesh on the back and down the walls to 1.5 m from the sill

As specified by Pretium, the bolt spacing for the Super Swellex can be adjusted as required to attain the design FOS, but it is not feasible for Brucejack to adjust the bolt length for the Super Swellex due to supply chain limitations.

2.2. Design Methodology

Overall excavation stability was assessed using Grimstad's (2007) empirical design chart for each rock mass condition (average and poor, as defined above).

Kinematic stability analyses were conducted using wedge stability analysis software Unwedge© (Rocscience 2017) to develop minimum ground support recommendations for the full width undercuts in each structural domain (BGC 2013). Discontinuity design sets in each structural domain were defined by considering orientation frequency and sampling method, similarity to major structure, and prominent structure type within each set. Discontinuity strength properties for each structural domain are described in BGC (2013). In-situ stresses were not considered; this adds a degree of conservatism to the analyses, as clamping forces are ignored. Joint set persistence was assumed to be 2.5 m, and fault set persistence was assumed to be 7 m, based on the average observed persistence of discontinuity sets during BGC's 2016 annual underground inspection (BGC, 2016). BGC notes that longer persistence values can significantly impact the results of the Unwedge analyses; if such conditions are observed underground, the current analyses should be reconsidered.

All possible combinations of discontinuity sets were analyzed to assess the adequacy of prescribed ground support to prevent wedge failure. Analyses were run for a range of drift orientations (180° to 270°) to assess stability conditions for proposed access and stoping arrangements.

All mesh is assumed to be 100 mm x 100 mm x 4.0 mm (8 gauge) wire. The Super Swellex (PM24C) and plate are assumed to have a minimum breaking strength of 240 kN and 180 kN, respectively, with an assumed bond strength of 170 kN/m. The standard SS39 Split Set Stabilizer rock bolts are assumed to have a minimum breaking strength of 105 kN. Shotcrete and/or mesh is not considered as a stabilizing component in the factor of safety calculations, but is assumed to be installed as per Pretium (2016) to retain the integrity of the rock mass at the drift boundary.

The full width undercuts are assumed to be "temporary" headings with a design Factor of Safety (FOS) of 1.2. It was assumed that wedges less than 1.0 m^3 (2.7 tons) will be adequately retained by surface support (shotcrete or galvanized welded wire mesh).

3.0 ANALYSIS RESULTS AND SUPPORT RECOMMENDATIONS

Appendix A presents a summary of the overall rock mass stability using Grimstad's (2007) empirical design chart. At the given full width span of 15 m, and assuming an excavation support ratio (ESR) for temporary mine openings, the PM24C long support is predicted to achieve the

design intent with respect to overall rock mass stability of the undercuts in both “good” and “poor” rock mass conditions.

To assess kinematic stability using Unwedge© (Rocscience 2017), the following assumptions were made:

- Joint friction angle is 35°
- Joint cohesion is 0 MPa
- Joint persistence is 2.5 m
- Fault friction angle is 30°
- Fault cohesion is 0 MPa
- Fault persistence is 7 m
- The mean set orientation for the design discontinuity sets in each domain was assumed as defined in BGC (2013)
- The long support design in a drawing (“Brucejack Ground Support Types R1(2017)”) provided by Pretium showed only the pilot drift, with the cable bolts in the shoulder angled outwards at approximately 45°. The original design intent for the full width undercuts (BGC 2013) was for effective full-width cable bolt support. Both geometries were analyzed.

Example Unwedge analyses and the associated inputs are shown in Appendix B. For the assumptions defined above, 4.88 m long connectable Super Swellex (PM24C) installed on 2.4 m spacing are a suitable replacement for the 6 m long single strand bulbed cables. For ore drifts, the full-width condition represents the ‘worst-case’ geometry. Unwedge© analyses of these conditions with the prescribed support indicate a low likelihood of failure, with all wedge geometries that have FOS values lower than the design threshold of 1.2 predicted to have volumes that should be adequately retained by the near surface support (welded wire mesh).

In summary, the revised ground support for the 15 m full width undercuts (15 m width by 5 m height) is:

- 2.4 m long SS39 split sets on 1.8 m spacing in the back and walls
    - Bolts in adjacent rows should be offset by a distance equal to half the row spacing.
- 4.88 m long connectable Super Swellex (PM24C) on 2.4 m spacing in the back
    - Bolts in adjacent rows should be offset by a distance equal to half the row spacing.
    - Three Super Swellex per row (one mid-span (vertical), and one angled into each shoulder of the pilot drift).
- Welded wire mesh or shotcrete in the back and walls to retain the integrity of the rock mass at the drift boundary.

The results of the kinematic stability analysis, which include a limited amount of sensitivity analysis on discontinuity properties, indicate that the adequacy of the ground support is heavily sensitive to the persistence of the joints and faults in the full width undercuts. Specific recommendations on how to manage residual risk for rock fall are provided in the next section.

4.0 CONCLUSIONS AND RECOMMENDATIONS

BGC's analysis indicates the 16' (4.88 m) connectable Super Swellex (PM24C) will generally achieve the design objectives for long support in the full width undercuts. However, the following items were noted by BGC:

- Due to adverse orientation of some of the discontinuity sets in the Brucejack rock mass, there will remain some residual risk for rock fall in the full width undercuts despite the installation of the ground support summarized in this memo. The risk for that rock fall increases where the discontinuities are persistent (greater than half of the cross-cut span) and closely spaced (less than half of the cross-cut span). The existing geotechnical database is insufficient to predict where these more persistent and/or closely spaced discontinuities may occur, therefore thorough geotechnical inspections and routine scaling of the workings throughout the development cycle should be carried out to help mitigate the residual risk.
- When poorer quality rock masses and/or persistent structure(s) are encountered, customized support designs which address local conditions are required. Additional support may include simple modifications such as reducing the spacing on the Super Swellex, or more complex solutions targeting specific zones or features.
- Underground mining personnel will need to assess if underground rock mass conditions closely match the assumed conditions. Should different or atypical conditions be encountered, then the design supplied herein may not be appropriate or valid. BGC should be consulted if different or atypical conditions (rock mass, groundwater, stress regime, blast fragmentation, etc.) are encountered to determine if alternative support requirements are required.
- Mucking level brows of full width undercuts should be regularly inspected by qualified geotechnical staff and mining supervisors for signs of rock mass damage, raveling, and failure within the back and ribs.
- All support (short and long) should be installed in timely manner (ideally "in-cycle") and subject to a rigorous QA/ QC program.
- Rehabilitation of damaged zones of rock within full width undercuts should be carried out as soon as practical.

It is recommended that all standard ground support designs be reviewed and updated annually, as additional operational experience, structural data, stress regime data, and excavation performance data becomes available.

DRAFT

Introduction

BGC Engineering Inc. (BGC) visited Pretium Resources Inc. (Pretium) Brucejack Gold Mine (Brucejack) in support of an ongoing Ground Control Management Plan (GCMP) audit and review under Pretium PO 1025470 (BGC, October 26, 2018).

The site visit for the GCMP audit occurred on December 1 and December 2, 2018

A ground fall of approximately 2,500 m^3 had recently occurred during extraction of secondary stope #17 on the 1350 Level. No injuries or equipment damage resulted from the ground fall.

During the site visit, Pretium requested that BGC complete a geotechnical assessment of Brucejack's proposed secondary stope extraction mine plan and associated ground support designs to minimize the potential for ground falls during secondary stope extraction.

Scope of Work

The scope of work for the assessment summarized in the following slides is:

- Review the proposed mine plan for secondary stope extraction, and assess the potential for ground falls to occur during secondary stope extraction.
- Complete a preliminary geotechnical analysis of the 1350-17 ground fall to identify the probable cause(s).
- Provide recommendations to reduce the potential for ground falls to occur during secondary stope extraction.

Terms of Reference

BGC and Pretium Mine Technical services (MTS) staff have established the following terms of reference for the current SOW:

- Recovery of ore should be maximized due to the high value of Brucejack ore.
- Level development within the mine is established at 30 m level spacing and 15 m cross-cuts, therefore neither reduction of stope heights nor reduction of stope strike length is currently feasible
- Ground support costs are a relatively small component of the overall mining costs at Brucejack.
- Non-worker entry mucking techniques are standard practice , and continue to be recommended by BGC following all stope production blasts.

Mining at Brucejack

- The mining method at Brucejack is long-hole (blast-hole) open stoping, with the majority of stopes planned in a transverse orientation.
- Stope heights are 30 m (sill to sill), and cross-cuts are spaced on 15 m centers (i.e. transverse stope strike length is 15 m).
- Stope widths are designed at 15 m. Sill levels are spaced at 120 m (i.e. 1440 L, 1320 L, 1200 L).
- Stopes are excavated in a primary-secondary sequence from the bottom-up within an individual stoping block between sill levels.
- The mining sequence in any lens of a given mining block begins with the extraction of the primary stopes on the first (lowest) level. Wherever possible, the first primary stope will be located near the middle of the lens to develop a pattern of stope extraction that moves outwards to the extremities of the lens while progressing upwards towards the top. As confirmed by 3D numerical modeling (discussed below), this generally promotes a favourable redistribution of ground stress, although many smaller lenses in the Brucejack orebody are either irregular in shape or of insufficient dimensions to properly develop this sequence.

Ground Control Management is required over the life of the mine, during the design, planning, development, and operational stages. Ground control management should be **(and is currently)** approached in a systematic manner, and takes into account the following factors:

Geological and Geotechnical Factors:

- Distribution of rock types;
- Distribution, orientation, and condition of regional and local geologic structures;
- Ore zone location and grade;
- Geotechnical conditions of the rock mass;
- Rock strength parameters (uniaxial compressive strength, cohesion and friction angle, etc.);
- In-situ stress conditions and anticipated changes arising from mining;
- Groundwater conditions; and
- Ground response to mining determined from monitoring and surveillance.

Mining Factors:

- Excavation dimensions;
- Mining method and sequencing;
- Required use of excavation;
- Required service life of zone or excavation; and
- Ground support requirements, equipment, and constraints.

Stope Extraction Plan

- For Primary stopes to date partial and full-width overcut and undercuts have typically been establishing starting with a 5 m pilot drift, initially supported using 2.4 m long SS39 split sets on 1.8 m spacing and 4.88 m long connectable Super Swellex (PM24C) installed as a fan of three bolts into the back of the pilot drift.
- The pilot drift is then slashed out to the full 15 m stope width, to allow parallel production hole drilling across the entire width of the stope thereby increasing drilling precision and helping to maximize recovery. The full-width is excavated in 2.5 m wide slashes, with one 4.88 m long connectable Super Swellex (PM24C) installed in the back of each slash (a total of ~four additional Super Swellex are installed in the back during the full-width slashing).
- A 750 mm pilot hole is drilled in the slot raise location.
- Production drilling occurs in the raise and slot area, followed by production rings as drilling progresses to the ore contact.
- The stope is then blasted and mucked, with remote mucking required by Pretium once the drawpoint brow is open to the extent that the operator may be exposed to uncontrolled sloughing from the stope cavity. This continues to be the recommended practice.
- Once empty, the stope is remotely surveyed with cavity monitoring equipment (CMS). This is an important step for to reconciliation tasks and adjacent stope planning and requires completion in a timely manner.
- A paste backfill barricade (either shotcrete arch or muckpile) is constructed, and the stope is backfilled with fresh paste distributed directly from the paste plant on surface.
- **Secondary stopes are now regularly being scheduled for development and production**, with Pretium MTS seeking to optimize mining actives with specific reference to, and integration of, local conditions and mining conventions (i.e. geology & geotechnical controls, available mining equipment , standard development dimensions, scheduled production requirements, stope access plans, ventilation requirements, paste distribution system, risk tolerance etc.)

1350 to 1320-17 Stope Instability

- During recent extraction in November 2018 of the 1350 to 1320-17 stope, blast damage occurred in the walls and back of the 1350-17 cross-cut.
- The damaged zones were scaled and supported with 6 m long cable bolts on 2.5 m by 2.5 m spacing.
- When production drilling commenced from the top cut for the 1380 to 1350-17 stope, a ground fall occurred in the 1380 to 1350-17 stope.
- Drilling crews reported losing water down the production holes, and hitting a slip in one at approximately 17 m depth.
- This slip is inferred to be a large geologic structure possibly related to the moderately dipping structure visible in the right wall of the 1350-17 cross-cut A schematic of the ground fall is shown below.
- Total mass of the failed volume of rock has been roughly estimated @ 2600 tons

View from 1350-17 cross-cut, showing blast damaged zone and ground fall

Geotechnical Model

- Typical Rock Mass Classification values range from ~60-80 RMR / GSI, Q' = 2-20+, generally classified as "Good Rock"
- MTS geology and geotechnical engineering staff regularly visit the active faces during development of the cross-cuts, undercuts, and top cuts.
- This task is an important component for informing mine planning for adjacent stopes, and should be completed in a timely manner.
- **Current experience at Brucejack indicates largely structurally driven rock instability vs. stress driven instability . Stress impacts are likely to become a larger contributor to instability as mining depths increase.**
- **Custom support design using a combination of enhanced near surface support and deep fully grouted support are likely to be required where persistent geologic structure , poorer quality rock or fault zones are encountered.**

To assess kinematic stability using Unwedge© (Rocscience 2017), the following assumptions were made:

- Joint friction angle is 35°
- Joint cohesion is 0 MPa
- Joint persistence is 2.5 m
- Fault friction angle is 30°
- Fault cohesion is 0 MPa
- Fault persistence is 7 m
- **Current experience at Brucejack indicates largely structurally driven rock instability vs. stress driven instability . Stress impacts are likely to become a larger contributor to instability as mining depths increase.**
- The mean set orientation for the design discontinuity sets in each domain was assumed as defined in BGC (2013)

Permissible Stoping Dimensions

BGC has developed design recommendations for stope backs and walls using the empirical "Stability Graph" method (Hutchinson and Diederichs, 1996, and Nickson, 1992, after Potvin et al., 1988) . Geotechnical and stope geometry parameters are combined to determine a "Stability Number" (N'), defined by:

N' = Q' x A x B x C

Where:

- Q' is a rock mass classification parameter
- A is a measure of the ratio of intact rock strength to applied stress
- B is a measure of the relative orientation of dominant structure with respect to the excavation surface
- C is a measure of the influence of gravity on the stability of the face being considered.

Cconservative and base case Q' values of 10 and 40 respectively were used in combination with conservative A, B, and C inputs to calculate permissible stoping dimensions (hydraulic radii).

Statistical observations of the Brucejack dataset indicated that regardless of lithology, alteration, geological domain, or geotechnical unit, less than 20% of mapped or logged data had a Q' value less than 10, and greater than 50% of the rock had a Q' value of 40 or more.

Stability Analysis Inputs

Parameter	Value	Design Assumption
Q'	10 – 50	Domain 1
Q'	3 - 10	Domain 2
A	0.1 (back) 1.0 (walls)	Assume induced stress concentrates in back and that the walls are destressed.
B	0.3 (walls) 0.6 (back)	Based on weighted average structural variability in all domains
C	2 (backs) 4 (walls)	Defined based on critical discontinuity set assuming horizontal structure in back and adversely oriented sliding structure in walls.

Results from the stability method analysis include :

- Unsupported stope heights of up to 60 m may be achievable. However, as stope heights increase, so will the likelihood for large structurally controlled failures. At 60 m stope heights, Pretium should anticipate a requirement for cable-bolting of the hangingwalls and end walls, where accessible and practical (i.e. on 30m sublevels, for instance) . Paste stability at these dimensions has not been assessed for this study.
- Achievable stope widths and lengths will be largely governed by the stability of the stope backs. The design cases presented below indicate unsupported stope widths or lengths of 20 m may be achievable, with increased lengths in one dimension achievable with a reduction in the other.

X 4 Provides Tensile Strength for Pendant Pillar

The current stope extraction plan at Brucejack results in secondary stopes with sidewalls of paste, a fully exposed footwall (via slot), and a fully exposed sill (via the full width undercut). When the topcut is slashed to full width, the stope is therefore mostly supported by the shear strength of the rock to rock contact at the hangingwall, with a nominal amount of support provided by the shear strength of the paste in the sidewalls.

Deadweight calc's for the entire secondary stope block mass have been completed to determine required tensile strength to maintain pillar stability (in the absence of large structure)

- Block is ~ 20,000 t (200 MN) for 15 m Strike (15w x 15l x 30h x 2800kg/m3)
- 4m x 5m x 5m = 100m^2 x (2.5 - 5.0 MPa) Rock Tensile strength = 250 - 500 MN available
- Block is ~ 40,000 t (400MN) for 30 m Strike (15w x30l x 30h x 2800kg/m3)
- 4 x 12.5l x 5w = 250m^2 x (2.5 - 5.0 MPA) tensile strength = 625 - 1250 MN available

(Note: Paste side friction and FW Rock Contact not included)

Cable Reinforcement of Deadweight Block

20 m High Block is ~ 12,600 tons for 15 m Strike
(15w x 15l x 20h x 2800kg/m3)

10 m High Block is ~ 6,300 tons for 15 m Strike
(15w x15l x 10h x 2800kg/m3)

Equal to ~ 28 tons / m2 for 10 m High cut
Equal to ~ 56 tons / m2 for 20 m High cut

1m x 1m pattern is ~ 196 Cables in a 15 x 15 cut

Double Strand Bulbed Cables ~ 50 – 60 t / hole
~200 x 50-60t = 10,000 to 12,000 tons available

- Wide 'Stable' spans intersected by geologic structure or poorer quality rock required enhanced / deep patterned support consisting of minimum 6m long coupled Super Swellex or cement grouted cable bolts (0.7" dia, bulbed, dual strand ~ 30-35 ton capacity/strand, nominally >50 t / hole installed capacity)

- Current designs are for nominal rock mass, absent of large scale or controlling geotechnical structure

- If structure is present (as observed in some of current secondary stopes) dead weight analysis of rock wedge / block is required to confirm adequate bolt capacity

DYWIDAG-SYSTEMS INTERNATIONAL

Geotechnical Considerations

- Structure - **Current experience at Brucejack indicates largely structurally driven rock instability vs. stress driven instability .**
- Stress – Rock Stress conditions are currently assessed using visual observations only. Consider upgrading stress monitoring program to include a network of MPBXs and Stress Cells. Stress impacts are likely to become a larger contributor to instability as mining depths increase.
- Rock Mass – Time Rock Mass Classification and geologic assessment tasks are import to the stope planning and execution process . Rock mass conditions require continuous evaluation with related adjustments made to ground support systems

Operational Considerations

- Revisit Secondary Stope Blast Designs , particularly adjacent to paste walls.
- Install appropriate , custom ground support specific to local conditions in a timely manner, as soon as possible following excavation.
- Drill production holes parallel to paste walls where possible
- Consider a primary / secondary/ tertiary stoping sequence where 'key stopes' (those stopes connecting two or more paste filled stopes on either side, are mined low grade material and when practical towards the end of mine life.
- Where possible consider alternate stope access geometries (i.e. rear-access) and paste distribution geometries to optimize local conditions

The following slides are representative examples of typical RS3 analysis results. These were used to help develop designs, confirm / modify engineering judgement, and inform conclusions and outcomes of the underground assessment.)

A number of scenarios run with varying sequences, stages, material inputs and boundary conditions, using ranges of values determined from review of geotechnical model.

Geotechnical Model

(this data used as input for RS3 stress analysis modeling to assess stability impacts resulting from range of anticipated conditions)

VOK D1 / D2 / D3 Rock Strength Envelope

Unit	UCS – Lab (MPa)	Average Is50 (MPa)	K	UCS – Design1 (MPa)	Brazilian Tensile Strength (MPa)	Hoek-Brown Material Constant, mi	Unit Weight (kN/m³)	Young's Modulus (GPa)	Poisson's Ratio

Project:	Subject:
Brucejack Project – Geotechnical Assessment of Secondary Stopes Project Number: 1008030	BJ Secondary Stoping Conceptual RS3 Stress Assessment and Ground Support Model – Stage 4 Sig1
	Date: 1/19/2019 Page 27

- Results form the models indicate that at current and near-term planned depths mining of the Brucejack orebody is unlikely to induce rock-bursting or cause un-manageable yield (or failure) within proposed sill, rib, or cross cut pillars. Standard empirical and analytical analysis techniques demonstrate that the proposed mine and pillar geometries are feasible and are likely to be stable.

- Preliminary stress analyses corroborate this, as well as highlight areas within the mine where elevated (but not un-manageable) stress conditions are anticipated as a result of mining activities. As expected, these tend to concentrate at various stages of the mining cycle, particularly within pillars and zone abutments. These and other locations of geotechnical interest should be monitored closely as mining progresses, with step-wise increases to ground surveillance and monitoring programs as required, as determined by pre-defined event-triggers and responsive actions specified in the project's Ground Control Management Plan.

- RS3 analyses are considered suitable for studying the evolution of mining-induced stresses, but are not considered suitably calibrated to estimate precise magnitudes of stress, strain, or infer absolute degrees of rock mass damage resulting from progressively failing / yielding rock (i.e. progressively micro-cracking, spalling, non-recoverable plastic deformation, and, in extreme cases, rock-bursting).

- The models' limited capacity arises from the current level of knowledge (or lack thereof) regarding the local geometry, in-situ stress conditions, local and intermediate-scale structural features and geotechnical 'zoning', etc. All of these can significantly constrain the extent to which the model can be used to accurately predict local and global rock mass behaviour during mine life.

- However, the model results can be reviewed with the goal of highlighting areas where stress is concentrating, where stress shadows (loss of confinement, or relaxation) are occurring, and where standoff distances or pillar thicknesses are not sufficient to isolate a critical openings from significant mining-induced stress changes.

- Typical results are presented in the figures above, illustrating maximum principal effective stresses 'Sigma 1', total displacements for various sequence phases, strength factors etc. As anticipated, at current depths the results indicate moderately increased loads in the 'secondary' stopes that serve as rib pillars during the primary stoping phase, as well as slightly increased loading in the rib pillars separating the cross cuts. Other mining steps indicate stresses concentrating in the sill region as mining progresses upwards, similar to that described in the excerpt provided. Analogous models run at deeper depths indicate a predicable increase in stress influences on stability.

Further RS3 model results are included in an appended slide package for review and discussion.

- The current design sill pillar thickness is 30 m. The numerical modelling analysis shows some relaxation in larger stope hanging walls, and stress concentrations in sill pillars within areas of the mine with denser stoping. The model shows that the bottom-up sequence concentrates stress in both VOK Zone sill pillars. Yielding is likely to occur prior to recovering the entire sill pillar, and therefore achievable sill pillar recovery may be less than 100%.

- The rib pillars between the open stoping blocks are intended to give temporary support to the mining block until the primary stopes are backfilled and the pillar can be recovered in the form of a secondary stope. Analyses of "conservative / low strength cases" indicates that *higher pillar load to UCS ratios may develop with increasing depths, within the pillar cores, resulting in an increased potential for progressive pillar damage, such as pillar cracking and or surface spalling, as Load to UCS ratios approach and exceed 0.5.*]

- If such a case arises, a number of mitigative measures could be used to remedy potential rib pillar deterioration, including increased localized reinforcement of the pillars with bolts, screen, straps and / or shotcrete (where accessible), or alternatively, a change in the local excavation geometry and /or mining sequence.

Common Damage Scale

The RS3 stress assessment results include the maximum shear strain predicted throughout the modeled zone.

It is notable that the indicated strain is substantially below the 2% to 3% typically required for the onset of significant ground deterioration.

The Common Damage Scale (Beck and Duplancic, 2005) presents a useful empirically-tested correlation of modeled plastic strain vs expected rock mass damage.

	Class	Description
	Very Significant	Drive surface heavily deformed, drill holes crushed, support visibly loaded. → Substantial rehabilitation required to prevent frequent falls of ground
	Significant	Any or all of: Buckling, dilation of existing structure or induced fractures, failed corners and brows, hole problems. Bulking of the mesh is present in some areas. → "Spot" rehabilitation required to maintain access, more substantial rehabilitation required for drill and blast activity etc. Hole problems develop
	Moderate	Shearing on existing structure, visible yield. Frequent scats in the mesh, or material may be spalling under mesh. → Rehabilitation required only when intense activity will be undertaken in the area (ie drill and blast). Drive still safe for travel. Holes show more frequent signs of damage, sometimes requiring re-drilling.
	Minor	Minor signs of strain or displacement on persistent structures, some occasional scats in mesh. → No rehabilitation required.
	None	Blast damage/virgin stress damage only → Primary support controls drive surface

Paste Backfill

Primary backfilling material, with high-strength (1.1 MPa) used in the lower portion of primary and secondary stopes on the sill level where paste will be undercut during sill excavation

Regular strength (400 kPa) used in primary stopes where vertical paste re-exposure will occur during secondary stope extraction

Low strength (200 kPa) paste or unconsolidated waste rock used to backfill secondary stopes that will not be re-exposed by adjacent mining.

Paste Backfill QA QC

A Quality Control Quality Assurance for paste has been implemented which was broadly reviewed by BGC. During the December 2018 site visit

Data suggests a wide range of strength results from sample test results, with mean values generally achieving design standards. Additional data is required from now fully commissioned paste plant to establish long term quality trends.

Uncertainties remain regarding the assessment of paste fill exposures for various stoping configurations and the impact of paste strengths of overall stability, particularly for dimensions that approach the larger range of those contemplated as part of the mine design (e.g.. 30 m high x 30-plus metres long x 15 m wide).

Confirmation and on-going coordination with the project paste design engineers (AMC) is recommended, particularly as secondary stopes are now being developed.

Paste may possibly be used as a local stabilizer for stope shoulders, by overfilling and 'mining thru paste' to re-establish stable and controlled access for bottom cut development following blasting. The mining practicalities, paste strength requirements and possible advantages of this approach should be investigated.

- Top cut will become mucking sill for next level, may possibly be slashed full width depending on local geotechnical conditions, support requirements, mining preferences and recovery objectives. Support costs may be prohibitive.
- Shown with 'Mining-thru-Paste' concept - may assist with support of stope shoulders for bottom cut re-development. Higher strength paste used to provide artificial area support walls and prevent slope further deterioration.

Geotechnical Monitoring at Brucejack

An observational 'mine and monitor' risk management system will be employed at Brucejack, as part of the GCMP. Similar to the current state of practice for monitoring in underground mines in North America, Brucejack's planned ground monitoring system includes, progressively :

- Visual geotechnical inspections of mine workings
- Tape extensometer stations
- **CMS and monitoring prisms , rectified and reconciled to the mine coordinate system**
- **Vibrating wire and / or manual crackmeters**
- **Time domain reflectrometry (TDR) cables in excavation walls**
- **Multi-point borehole extensometers (MPBX) in pillars and walls**
- **Borehole stress meters**
- **Spatially Accurate 3D Mine Model as contiguous solids**
- **In-situ Stress Testing and Micro-seismic systems** , as appropriate

(items for advancement highlighted in blue, for discussion / consideration)

The various hardware systems noted above should be augmented with an appropriate suite of software to provide near real-time visualization, displacement calculations, monitoring, and warnings for the geotechnical and operations staff of the mine. Of particular significance will be the excavations near and within the Brucejack Fault Zone, the underground crusher chamber, and crown, rib, and sill pillars.

Regular visual geotechnical inspections of all mine workings are to completed by Pretium and / or their contractors

Deformation monitoring of critical stope walls, pillars, and infrastructure excavations such as shops, service bays, crusher chambers, primary developments, main access ramps, ventilation infrastructure etc., should be initiated as mining progresses. This monitoring is required to:

- Maintain safe operational practices for personnel and equipment
- Provide warning of rock mass instability
- Provide geotechnical information for designs to assist in making subsequent modifications, should they be required, to achieve the desired rock mass performance.
- If field observations and performance data indicate the progressive development of un-anticipated / anomalous / elevated stress conditions (similar to those noted in the 'Common Damage Scale'), or growing uncertainties with respect to Pretium's understanding of evolving stress conditions, monitoring programs and related instrumentation will be progressively upgraded until the necessary levels of surveillance are achieved and maintained.

MPBX

(Multi-Point Borehole Extensometer)

Typically has ~five or more anchor points and an integrated electronic readout head.

Specifications

Length: up to 100 m

Diameter: 33 mm

Weight: 0.5 kg/m

Borehole diameter: 50 mm minimum

Applications

Monitoring of underground excavations including walls and backs of mining drifts

Surface crown-pillar monitoring

Backfill monitoring in underground mines

Tunnels and dams on surface

Example Monitoring Locations for Current 1220 L to 1290 L Stoping Zone

Stress Cell

Operating Principle

The stressmeter consists essentially of a high strength steel proving ring wedged tightly across one diameter of a borehole drilled into the rock. The distortion of the proving ring, caused by changing rock stresses, is measured by means of a vibrating wire. Changes in rock stress cause changes in the resonant frequency of vibration of the tensioned wire, and the two are related by means of calibration data supplied with each stressmeter.

• Model 4300 installation in hard rock

• Model 4300 installation in soft rock, using a soft rock shoe and soft rock platen.

• Model 4300 details and installation tool assembly.

RECOMMENDATIONS

- **Mining of Secondary Stopes should be limited to a 5-m wide top cut. General case stability analyses indicated a cross drift to allow for parallel drilling is unlikely to adversely impact stope stability vs. a full width slash.**
- Due to adverse orientation of some of the discontinuity sets in the Brucejack rock mass, there will remain some residual risk for rock fall in the full width undercuts despite the installation of the ground support summarized in this memo.
- The risk for that rock fall increases where the discontinuities are persistent (greater than half of the cross-cut span) and closely spaced (less than half of the cross-cut span). The existing geotechnical database is insufficient to predict where these more persistent and/or closely spaced discontinuities may occur, therefore thorough geotechnical inspections and routine scaling of the workings throughout the development cycle should be carried out to help mitigate the residual risk.
- When poorer quality rock masses and/or persistent structure(s) are encountered, customized support designs which address local conditions are required. Additional support may include simple modifications such as reducing the spacing on the Super Swellex, or more complex solutions targeting specific zones or features.
- Underground mining personnel will need to assess if underground rock mass conditions closely match the assumed conditions. Should different or atypical conditions be encountered, then the design supplied herein may not be appropriate or valid.
- Mucking level brows of full width undercuts should be regularly inspected by qualified geotechnical staff and mining supervisors for signs of rock mass damage, raveling, and failure within the back and ribs. All support (short and long) should be installed in timely manner (ideally “in-cycle”) and subject to a rigorous QA/ QC program.
- Rehabilitation of damaged zones of rock within full width undercuts should be carried out as soon as practical.
- It is recommended that all standard ground support designs be reviewed and updated annually, as additional operational experience, structural data, stress regime data, and excavation performance data becomes available.
- Consider modifying the standard ground support for full-width undercuts. Longer length and higher-capacity support than the 4.8 m SuperSwellex is required to achieve design FOS if persistent geologic structure intersects the stope. Analysis completed as part of this assessment indicates that 6 to 15 m long 0.7 inch diameter double-strand bulbed cables (or equivalent ~ 50 ton element) on a 1.0 to 1.5 m by 1.0 to 1.5 m staggered pattern may be required achieve design FOS’s for some of the larger wedges potentially formed by persistent geologic structure. In these cases full widths cuts may well be preferentially / selectively avoided.
- Review production blast designs with the intent to minimize blast-induced damage in the rock mass.
- Consider reducing the stope lengths and access options, locations of backfill placement , particularly when persistent and adversely oriented structures are mapped in the stope cross-cuts.
- Paste may possibly be used as a local stabilizer for stope shoulders, by overfilling and ‘mining thru paste’ to re-establish stable and controlled access for bottom cut development following blasting. The mining practicalities, paste strength requirements and possible advantages of this approach should be investigated.

Limitations

Ground support system- development into paste backfill

SUPPORT PLAN FOR PASTE BREAKTHROUGH

Section View - Looking East

Step #1

1. Excavate 2m of paste at the full dimensions of 5.2mW by 5.1mH.

Step #2:

1. Apply the initial layer of 50mm thick shotcrete from sill to sill to cover the first round of exposed paste.

Step #3:

1. Wait for 6 hours to let shotcrete to cure;
2. Install Wire Mesh Screen and 2.1m split sets with 1.0m by 1.0m spacing.

Step #4:

1. Excavate 2m of paste for the next round;
2. Apply initial layer to the current round and 2nd layer to the previous round of 50mm thick shotcrete;
3. Repeat the steps from 1-4 until the 23m paste breakthrough development is complete.

Note:
1. Drift is to be excavated with arch back. The straight wall height is to be 4m before curve starts.
2. 2.1 m long Splitsets are to be installed at 1m by 1m pattern as shown in the section view
3. Shotcrete curing time is 6 hours before working underneath.
4. When second layer of shotcrete is applied, screen, bolts plate are to be fully covered.

SUPPORT PLAN FOR MINE BESIDE PASTE

Drift with Paste Wall Exposure

Advance (m)		3.6 m (2.0m as required by Geotech Eng)
Rock Bolt	Back	2.1m Long Split Set (1.2m by 1.2m spacing)
	Wall (Rock)	2.1m Long Split Set (1.2m by 1.2m spacing) down to maximum 1.2m from Sill
	Wall (Paste)	2.1m Long Split Set (1.2m by 1.2m spacing) down to maximum 1.2m from Sill
Wire Mesh		Back & Walls - Down to maximum 1.0m from Sill
Shotcrete	Pre - SC	as Required depends on Paste Condition
	Post - SC	N/A
Secondary Long Support		4.9m Long Connectables to the Back as Required

Drift with Paste Wall/Back Exposure

Less than 1.0m Paste Back Exposure

Advance (m)		2.0 m
Rock Bolt	Back	2.1m Long Split Set (1.0m by 1.0m spacing)
	Wall (Rock)	2.1m Long Split Set (1.2m by 1.2m spacing) down to maximum 1.2m from Sill
	Wall (Paste)	2.1m Long Split Set (1.0m by 1.0m spacing) down to maximum 1.2m from Sill
Wire Mesh		Back & Walls - Down to maximum 1.0m from Sill
Shotcrete	Pre - SC	as Required depends on Paste Condition
	Post - SC	Paste Exposure (Min. 50mm)
Secondary Long Support		4.9m Long Connectables to the Back as Required

More than 1.0m Paste Back Exposure

Advance (m)		2.0m
Rock Bolt	Back	2.1m Long Split Set (1.0m by 1.0m spacing)
	Wall (Rock)	2.1m Long Split Set (1.2m by 1.2m spacing) down to maximum 1.2m from Sill
	Wall (Paste)	2.1m Long Split Set (1.0m by 1.0m spacing) down to maximum 1.2m from Sill
Wire Mesh		Back & Walls - Down to maximum 1.0m from Sill
Shotcrete	Pre - SC	Paste Exposure (Min. 50mm)
	Post - SC	Sill to Sill (Min. 50mm)
Secondary Long Support		4.9m Long Connectables to the Back as Required

Plan View

Note:

1. Shotcrete curing time is 6 hours before working underneath.
2. When second layer of shotcrete is applied, screen, bolts plate are to be fully covered.
3. Drift with more than 1m of paste exposure at the back will be considered as a drift break through and applied same support plan.

14.5.3 Cable installation

The left hand drawing in Figure 14.14 shows the traditional method of grouting a cable in an uphole. This method will be called the 'breather tube method'. The grout, usually having a water/cement ratio ≥ 0.4, is injected into the bottom of the hole through a large diameter tube, typically 19 mm diameter. The air is bled through a smaller diameter tube which extends to the end of the hole and which is taped onto the cable. Both tubes and the cable are sealed into the bottom of the hole by means of a plug of cotton waste or of quick setting mortar. As shown, the direction of grout travel is upwards in the hole and this tends to favour a grout column which is devoid of air gaps since any slump in the grout tends to fill these gaps.

Apart from the difficulty of sealing the collar of the hole, the main problem with this system is that it is difficult to detect when the hole is full of grout. Typically, the hole is judged to be full when air ceases to flow from the bleed tube. This may occur prematurely if air is vented into an open joint along the hole. In addition, a void the size of the bleed tube is likely to be left in the grout column. Therefore, it is preferable to stop grouting the borehole only when grout returns along the bleed tube. However, a viscous grout will not flow down a 9 mm bleed tube and so a larger tube is required.

An alternative method, called the 'grout tube method' is illustrated in the right hand drawing in Figure 14.14. In this case a large diameter grout injection tube extends to the end of the hole and is taped onto the cable. The cable and tube are held in place in the hole by a wooden wedge inserted into the hole collar. Note that care has to be taken to avoid compressing the grout tube between the wedge and the cable. Grout is injected to the top of the hole and is pumped down the hole until it appears at the hole collar. If a watery grout appears first at the collar of the hole, grout pumping is continued until a consistently thick grout is observed.

Provided that a very viscous mix is used (0.3 to 0.35 water/cement ratio), the grout will have to be pumped into the hole and there is little danger of slump voids being formed. However, a higher water/cement ratio mix will almost certainly result in air voids in the grout column as a result of slumping of the grout. The principal advantage of this method is that it is fairly obvious when the hole is full of grout and this, together with the smaller number of components required, makes the method attractive when compared with the traditional method for grouting plain strand cables. In addition, the thicker grout used in this method is not likely to flow into fractures in the rock, preferring instead the path of least flow resistance towards the borehole collar.

The procedure used for grouting downholes is similar to the grout tube method, described above, without the wooden wedge in the borehole collar. The grout tube may be taped to the cable or retracted slowly from the bottom of the hole as grouting progresses. It is important to ensure that the withdrawal rate does not exceed the rate of filling the hole so the air voids are not introduced. This is achieved by applying, by hand, a slight downward force to resist the upward force applied to the tube by the rising grout column. Grout of any consistency is suitable for this method but the best range for plain strand cables is between 0.3 and 0.4 water/cement ratio.

Modified cables, such as birdcage, ferruled or bulbed strand, should be grouted using a 0.4 water/cement ratio mix to ensure that the grout is fluid enough to fill the cage structure of these cables. Therefore, the breather tube method must be used for

these types of cables, since the grout flow characteristics required by the grout tube method is limited to grouts in the range of 0.3 to 0.35 water/cement ratio.

One of the most critical components in a cable installation is the grout column. Every possible care must be taken to ensure that the column contains as few air voids as possible. In the breather tube method, a large diameter breather tube will allow the return of grout as well as air. When using the grout tube method in upholes, a 0.3 to 0.35 water/cement ration grout will ensure that pumping is required to cause the grout column to flow, and this will avoid slumping of the grout in the borehole. A grout with a water/cement ratio of less than 0.3 should be avoided, since it will tend to form encapsulated air voids as it flows around the cable.

Figure 14.14: Alternative methods for grouting cables in upholes.

Construction	1 center wire & 6 outer wires		
Steel area	nom. 0.153 in^2 (98.7 mm^2)	nom. 0.217 in^2 (140 mm^2)	nom. 0.304 in^2 (196 mm^2)
Standing pitch	12-16 x diameter		
Weight per 1000 ft	520 lbs	740 lbs	1110 lbs
Weight per 1000 m	775 kg	1102 kg	1654 kg
Difference in wire size (center - outer)	min. 0.003" (0.076 mm)	min. 0.004" (0.102 mm)	min. 0.005" (0.127 mm)

Galvanized cable bolts available on request

Installation Accessories

Cable Bolts

End Holding Device - conventional style

- to hold cable bolt prior to grouting
- 2 straps ¾" x 2¾" (19 mm x 70 mm)
- suitable for 2" (51 mm) to 2.5" (64 mm) hole
- can be ordered separately and site installed
- if factory ordered, straps removed for shipping
- not available for double cable bolts

End Holding Device - fish hook style

- hooks swaged on with steel tubing
- hooks can be bent out to accommodate any hole size
- for single or double cable bolts
- fitting holds double cables together

0.5", 0.6" & 0.7" Machined Cable Grip - to fasten plates

- rated for full load of cable bolt
- Ø 1¼" (32 mm) for 0.5" cable bolts
- Ø 1½" (38 mm) for 0.6" cable bolts
- c/w 2 part gripper wedges
- available galvanized
- optional plastic cap to secure wedges during shipping

0.6" & 0.7" Cast Domed Cable Grip - to fasten plates

- rated for full load of cable bolt
- Ø 2" (51 mm) domed face
- c/w 2 part gripper wedges
- wedges available with or without groove & retaining spring
- available galvanized
- optional plastic cap to secure wedges during shipping

Installation Accessories

Cable Bolts

Passive Spinnable Cable Bolt - for resin installation

- 0.6" & 0.7" cable available
- resin anchored
- bulbs provide resin mixing and anchoring
- accepts 1⅛" square or hex male spinner
- available plain or galvanized
- cable available in any length
- factory assembled

patented item

Grout and Breather Tubing

- ¾" ID x ⅞" OD black poly tubing (400' roll)
- ¾" ID x ⅞" OD high density grout tubing (400' roll)
- ½" ID x ⅝" OD regular poly tubing (400' roll)
- ⅜" ID x ½" OD high density poly tubing (500' roll)
- black poly tubing rated for 100 psi
- yellow high density tubing rated for 200 psi

0.6" & 0.7" Dogbone Cable Coupler

- rated for full load of cable bolt
- used to join cables for slings or trusses
- used to wrap failing pillars
- requires 2 sets of wedges (included)

patented item

0.6" Cable Safety End Cap Grip

- for 0.6" cable bolts
- made from durable vinyl
- protects workers from sharp ends of cable

Cable Bolt

0.6" or 0.7" Passive and Tensionable

Cable Diameter	0.6" gr270	0.7" gr270
Weight	0.74 lbs/ft	1.11 lbs/ft
Bore Hole Diameter	1" to 1.375"	1" to 1.375"
Cross Sectional Area	140mm^2	196mm^2
Ultimate Load [1000lbs]	58.6	76.2
Yield Load [1000lbs]	46	68.6
Min. Elongation in 2ft	3.5%	3.5%
Typical plate	gr6 w/ 1$^3/_8$" hole	Grade 6

Also available are 0.5", 0.62" and 0.9" upon request.

- 270 ksi, low relaxation cable per ASTM A416.
- Supplied in any length, black or galvanized cable.
- Point anchored active bolt, tensioned after installation utilizing the hydraulic tensioning jack.
- Point-anchored passive bolt with pre-seated head. Wedge barrel shaped to accept 1⅛" hex or square male spinner.
- Several options for anchoring in the resin are available: The bulbed cable bolt is designed for point-anchoring in resin. It may also be fully grouted with slow speed resin, or cement grouts. Bulbing is an effective means to center the bolt in the drill hole, to mix the resin and to develop bond for anchoring the bolt.
- The Bond head is an additional bulb that can be formed on the end of the cable bolt.
- Bulbs are provided to fit hole sizes:
  - 1" hole: strip cage
  - 1⅜" hole: plunge bulb
  - 1¾" hole: bond head

CBJ-1 Cable Bolt Tensioning Jack

For installation of bearing plates

Specifications

- for 0.6" (15.2 mm) or 0.7" (17.8 mm) cable bolts
- maximum load 25 ton @ 10,000 psi (225 kN @ 70 MPa)
- stroke = 3" (75 mm)
- double acting hollow core ram
- aluminum construction - weighs only 10 lbs (4.5 kg)
- requires double acting hydraulic pump or hand pump
- L = 11.75" (300 mm)
- D = 4" (102 mm)

Parts

Seal Kit includes:

1 - 2.25" AN wiper
1 - 2.25" x 2.75" x 3.75" rod seal
1 - 1.25" x 1.75" x 0.250" rod seal
1 - 2.31" O-ring
1 - 2.875" T-seal

Cable Tensioner Mark2

For tensioning cables and installing plates

Specifications

A light weight and unique way for pre-loading cable bolts, the DSI Cable Tensioner Mark2 grips the end of the cable bolt and tensions it, leaving only a short tail protruding from the bearing plate (approx. 6 inch). The Cable Tensioner is a single hydraulic ram driven by an air/hydraulic pump or by machine hydraulics.

- The jack weighs 25 lbs. The entire kit (jack and pump) weighs 51lbs.
- Two grip handles allow for operation by one person.
- Unit locks on the cable, until lanyard is pulled to release spring loaded grippers.
- Can be configured for all cable bolts, from 0.6" to 0.7" and the DSI 0.9" HITEN cable bolt.
- Capacity: 48,500 lbs
- Bleed off: 15% i.e. cable lock-off load is 85% of pulling force due to seating loss. (for a typical 12ft bolt)

Operation

Install the plate and wedge barrel with wedge on the end of the cable bolt.

Push the Cable Tensioner on. It will self-lock onto the cable.

Tension bolt to the desired load per hydraulic gage included with the unit.

After stressing, the Cable Tensioner is easily removed by pulling on the lanyard to release the internal grippers.

The Wedge Anchorage of the Cable Bolt

The anchorage of most cable bolts consists of a wedge barrel and a 2- or 3-part wedge. The wedge segments grip the cable by means of tooth shaped threads which are forced into the surface of the cable wires.

The clamping force W is highly dependent on the friction between wedge and wedge hole. For normal friction conditions, the clamping force W is more than 4 times the cable pulling force V and it adjusts with the pulling force V.

Warning: If friction increases (due to corrosion), a larger F will reduce the clamping force. As V increases all other forces can only increase if the wedge can seat deeper into the barrel. If the wedge is restrained to do so (i.e. by corrosion or dirt-accumulation), the clamping force can not increase with the pulling force causing slippage when the load on the cable bolt gradually increases during service life.

To avoid slippages during use, it is important that the cable bolt is fully stressed at time of installation to a force equal to 0.5 Fu. (ie. 50% of the capacity of the cable)

When a wedge is properly seated, radial cracks may develop indicating adequate seating.

The wedge can be supplied with a rubber O-ring or a metal spring ring holding the wedge segments together.

Notes: USA - manufactured to ASTM F432 and ASTM A615 specifications; bolts MSHA approved
Canada - manufactured to ASTM F432, CSA M430 and CSA G30.18M specifications
Grade 40 & 75 available where applicable. Notched rebar optional for bending.

Installation Accessories

Rebar Rock Bolts

Nuts

Domenuts
- for ¾" thread A.F. = 1 ⅛" square
- for ⅞" thread A.F. = 1⅛" square
- for 1" thread A.F. = 1 ⅝" hex

Plain Nuts - used with pinched thread
- for ¾" thread A.F. = 1⅛" square
- for ⅞" thread A.F. = 1⅛" square with flange
- for 1" thread A.F. = 1⅝" hex

Torq Bolts - system available
- for ¾" and ⅞" thread A.F. = 1⅛" square

Resin Mixing System "crimped thread"

Reverse Spin Reverse Drive

Hardened Round Washers

- to ASTM F436 specifications
- for ¾" thread:
  I.D. = 13⁄16", O.D. = 1 15⁄32", T = 0.122" to 0.177"
- for ⅞" thread:
  I.D. = 15⁄16", O.D. = 1¾", T = 0.136" to 0.177"
- for 1" thread:
  I.D. = 1⅛", O.D. = 2", T = 0.136" to 0.177"

Spherical Seat (Compensation) Washers

- ductile iron ASTM A536 Gr. 65-45-12
- for ¾" thread:
  I.D. = 13⁄16", O.D. = 2", H = 13⁄16" (model TSW-4)
  I.D. = 15⁄16", O.D. = 2", H = ½" (model TSW)
- for ⅞" & 1" thread:
  I.D. = 1 1⁄16", O.D. = 2", H = ½" (model TSW-1)

Installation Tools - for Stopers/Jacklegs

Forged Head Rebar Driver (Dollie)
- 1 ⅛" square driver
- available with ⅞" hex socket or 3 ¼" long hex shank

Threaded Rebar Nutrunners
- 1⅛" square nutrunner (for ¾" & ⅞" bolts)
- 1⅝" hex nutrunner (for 1" bolts)
- available with ⅞" hex socket or 3¼" long hex shank

1 1/8" square nutrunner
with 7/8" hex socket
and optional ejector hole
for domenut "caps"

Rope thread and T-thread drivers and nutrunners available on request

I-D. Thread Bar Resin Anchored Rock Bolts

DYWIDAG-SYSTEMS INTERNATIONAL

DYWIDAG Threadbar Resin Anchored Rock Bolts

Lafayette Bluff Tunnel, U.S. Highway 61, Minnesota

DYWIDAG Threadbar Resin Anchored Rock Bolts

Resin bolts, bonded to rock or concrete by a fast curing polyester resin grout, are used extensively for slope stabilization, tie backs, tie downs, and rock bolts. The resin grout develops a bond superior to that developed by cement grout. Fast gelling resin allows transfer of load to the rock formation within minutes after installing the bolt.

DYWIDAG THREADBAR® provides a simple, economical, and rugged solution to both tensioned and non-tensioned rock bolts and rock anchors when installed with resin grout. Threadbar for prestressing, conforming to ASTM A722, is available in 1" (26 mm), 1¼" (32 mm), and 1⅜" (36 mm) nominal diameter. Threadbar for reinforcing, conforming to ASTM A615, is available in grades 60 and 75 for sizes #6 through #8, grade 75 for sizes #9 through #18, and grade 80 for 63 mm bar.

Dywidag Threadbar for prestressing and reinforcing have a continuous pattern of threadlike deformations along their entire length. More durable that machined threads, the deformations allow anchorages and couplers to thread onto a Threadbar at any point.

The rolled-in Dywidag thread pattern has no effect on the overall strength or effective area of the Threadbar. Conventional rebar and other steels have a reduction of 25% to 35% lin effective area when machined threads are applied.

The strength of Dywidag Threadbar anchorages and couplers, for prestressing, exceed the requirements of ACI 318. Test reports are available for the main components of the system. Anchorages and couplers for reinforcing Threadbar develop 100% of the ultimate nominal strength of the bar.

Available in mill lengths to 60', Dywidag Threadbar may be cut to specified lengths before being shipped to the job site or, where circumstances warrant, Threadbars may be shipped in mill lengths for field cutting with a portable friction or band saw.

Threadbars may be coupled to facilitate installation in confined areas of to allow removal of prebolted overcast and resetting of anchors. Dywidag Threadbar anchors can be extended into a structure or function as a form tie.

Dywidag Threadbars are used extensively for rock anchors because of their versatility, strength, performance characteristics, and off-the-shelf availability of most components.

Prestressing Steel Anchorage with Anchor Nut

Reinforcing Steel Anchorage with Bevel Washer

Reinforcing Steel Anchorage with Deformed Plate

The components of the DYWIDAG THREADBAR® system are manufactured in the United States and Canada by DYWIDAG-Systems International.

Polyester resin is packaged in cartridge form and is available in various diameters and gel times. The cartridge consists of a heat sealed tube of polyester film containing both the resin and the catalyst, which are separated by a barrier which prevents chemical interaction. The resin cartridges are placed in the bore hole before the Threadbar is inserted. The resin gels after the components are mixed during the installation of the Dywidag Threadbar.

Resin anchored rock bolts are installed in all types of rock of concrete. Track drills, tire mounted drills, jacklegs or storrpers may be used to both drill the hole and install the Dywidag bolt.

Dywidag resin anchors are used where expansion shells are inappropriate. The resin anchorage length is easily adjusted to fit the varying rock conditions. Resin anchored Dywidag rock bolts may be installed in bore holes located at any angle above or below the horizontal.

Tension bolts with resin point anchorage are used to apply a compressive force across layered rock strata. Tension bolts may be applied using fast setting resin as the point anchorage in conjunction with slow setting resin as a corrosion protection for the free stressing length. Bolt tension is applied after the fast setting resin has cured but before the slow setting resin cures. Untensioned dowels are fully encapsulated with resin and rely on movement of the rock strata to load the bolts.

Tensioned bolts with resin point anchorage.

Tensioned bolts fully resin anchored and grouted.

Untensioned dowels fully resin grouted.

Prestressing Steel
Wedge Washer
Assembly

Resin Cartridge

Some important notes concerning the safe handling of high strength steel for prestressed concrete:

1. Do not damage surface of bar.
2. Do not weld or burn so that sparks or hot slag will touch any portion of bar which will be under stress.
3. Do not use any part of bar as a ground connection for welding.
4. Do not use bar that has been kinked or contains a sharp bend.

Disregard of these instructions may cause failure of material during stressing.

All couplers and hex nuts develop 100% of the nominal ultimate strength of the bar
[1] 63 mm bars and hardware available in grade 60 material only
[2] Measured across flats

Resin anchors using DYWIDAG reinforcing steel may be proof stressed to 90% of the guaranteed yield strength of the reinforcing steel. The final working force varies with the application and function of the anchors.

Engage bar in coupler to a depth equal to ½ the coupler length.

Coupler | Plate Anchorage with Hex Nut | Anchor Nut & Deformed Plate | Anchor Nut & Bearing Plate

DYWIDAG Resin Anchor Design

Dywidag Threadbar reinforcing steel is intended for use in relatively low strength rock bolt and rock dowel applications. Dywidag Threadbar prestressing steel is intended for use in high strength applications to permit the maximum design load in each bore hole. The use of prestressing steel may allow a reduction in the number of bolts in the pattern and thus usually reduces drilling costs.

After drilling, each bore hole must be cleaned with either air or water before the resin cartridge is installed. Standing or flowing water does not affect the resin but may cause deterioration of the hole.

The bore hole and cartridge diameter must be compatible with the diameter of the threadbar specified. Bore hole diameters other than those suggested by the Resin Yield Chart may be used under special conditions. For these applications, testing may be necessary to demonstrate that the tools and procedures selected will sufficiently mix the resin with the catalyst.

Anchor plates vary in size and thickness depending upon the function and the bearing conditions. Bevel washers, flat washers or anchor nuts are required for Dywidag reinforcing steel. Wedge washers may be used with prestressing threadbars where the plate is not perpendicular to the threadbar.

Resin Strength vs. Cure Time

Dywidag Threadbars may be stressed to proof load an anchor or to induce a permanent load. The continuous threadlike deformations simplify stressing. Stressing is accomplished using a center hole hydraulic jack, torque wrench or air wrench.

The anchorage length varies with the structure of the rock formation. The properties of the polyester resin do not govern the design of the bond zone length.

All design assumptions should be verified by field tests.

Polyester resin grout is unaffected by blasting and provides a corrosion protection equal to cement grout. Resin is unaffected by fresh water, salt water, mild alkalies and mild acids.

The resin gel time and cure time are temperature sensitive. To insure proper behavior, the ambient temperature of the rock, or concrete must be monitored.

Gel Time vs. Temperature

Anchorage Strength vs. Bond Length

DYWIDAG Resin Anchor Installation

Drill and clean hole.
Drill smallest diameter hole which is compatible with the bolt and cartridge diameter selected.

Insert Resin Cartridges.
Use fast setting resin for bond length. If full encapsulation is desired, use slow setting resin or cement grout in the upper length to accommodate stressing.

Insert DYWIDAG Threadbar.
Spin bar with drill tool at about 100 rpm. Advance threadbar through cartridges while spinning. Spin for 30 to 60 seconds after reaching the bottom of the hole. Total spinning time should not exceed gel time.

Mount bearing plate and secure plate with anchor nut.
Wedge washers are required when anchor plate is not perpendicular to bolt.

Stress after resin has cured (when required).
Setting time varies from 1 to 20 minutes depending upon temperature and the resin type used. Apply tension with hydraulic jack, torque wrench or air wrench.

Monitor bolt tension.
The bolt tension is monitored by reading the pressure gauge where the hydraulic jack is utilized. Where torque or air wrench is utilized, the bolt tension is monitored by developing a tension-torque relationship curve for the specific application.

*Ratio of resin column length after insertion of Dywidag Threadbar to resin column length before inserting Dywidag Threadbar. Resin yield chart information provided by Celtite, Inc.

Yields are calculated; no waste or allowance for over drilling is included. Site trials should be conducted to determine actual resin requirements.

Example: When using 1" (26 mm) Dywidag Threadbar in 1½" (38 mm) diameter hole with 1¼" (32 mm) diameter resin cartridge, resin yield multiplier is 1.27. A 12" (305 mm) resin column yields 15" (381 mm) of resin after the insertion of the Dywidag Threadbar.

DYWIDAG Resin Anchor Applications

Toe Slab Rock Anchors. R.D. Bailey Lake Dam. Guyandot River, West Virginia. U.S. Army Corps of Engineers, Huntington District. 1" ϕ Grade 150 Dywidag Threadbars.

Roof Bolts in Diversion Tunnel. Paintsville Lake Dam, Kentucky. U.S. Army Corps of Engineers, Huntington District. #8 Grade 60 Dywidag Threadbars.

Stilling Basin Rock Anchors. Smithland Dam, Ohio River. U.S. Army Corps of Engineers, Nashville District. 1 1/4" ϕ Grade 150 Dywidag Threadbars.

DSI reserves the right to change the design or details of its products without notice. Specific information for job details and drawings should be obtained from your DSI Sales Engineer.

Portal and open cut face of Lafayette Bluff tunnel stabilized by 1,076 twenty foot long epoxy coated #11 Threadbar bolts.

3,214 #11 epoxy coated, resin anchored Threadbar bolts together with shotcrete form reinforced rock arch inside tunnel.

I-E. Swellex Bolt Specifications

Swellex connectable bolts
– long support

Swellex connectable rock bolt is an ingenious system. It is a true alternative as long secondary support to secure potentially unstable areas or to control dilution while boosting productivity. By simply connecting two, three or more specially adapted Swellex rock bolt segments, you create a custom-made long rock bolt, able to penetrate deep to stable rock.

Immediate support

It is ideal as secondary reinforcement in difficult areas, as long anchors in stopes for dilution control or where other long anchors have problems with excessive water.

Quick installation

No curing time! No special crew! Recent tests have shown up to four fold increased productivity when compared to manually and semi-mechanized installed cable bolts.

Peace of mind

By reaching recommended expansion pressure you are assured of a perfect installation on the entire length of the bolt irrespectively of presence of water in the hole.

Swellex connectables

General Information	Swellex Pm 24C
Minimum breaking load	240 kN
Minimum yielding load	200 kN
Minimum elongation	10%
Expansion pressure	300 bar

I-F. Split Set Stabilizers

INTERNATIONAL ROLLFORMS, INC.
SPLIT SET®

SPLIT SET® Stabilizers SS-33

Specifications and performance

The Split Set stabilizer is a slotted steel tube, with one end tapered for easy insertion into a drill hole. The other end has a welded ring flange to hold the bearing plate.

The stabilizer is inserted into a hole slightly smaller in diameter than the tube, using a simple driver tool fitted to the drill. As the tube enters, its diameter is compressed and the slot partially closes. This exerts radial forces along the length of contact with the rock, providing the friction which holds the rock together. The driving force of the drill actively loads the bearing plate against the rock.

International Rollforms' Split Sets feature a <u>patented</u> "Ring Indexing" feature. This allows for determining the length of an installed Split Set.

Tubes and plates are available standard or galvanized, made in accordance with ASTM F 432-95 where applicable. Code stampings on the tube show its size, date and place of manufacture, and heat lot of steel.

Model SS-33 Split Set stabilizers are 1.3 in. (33 mm) in diameter.

Stabilizers are packaged 6 per pack and 300 per pallet.

Also see Utility Hangers on page 2.

Domed bearing plate

Split Set domed bearing plates uniquely combine high strength with light weight, and are integral parts of the Split Set system. International Rollforms plates meet ASTM F 432-95 standards where applicable, providing a load capacity of 10 tons (9.1 metric tons) with minimal deflection.

INTERNATIONAL ROLLFORMS, INC.
SPLIT SET®

Installing the SS-33 stabilizer

The SS-33 tube has a nominal outside diameter of 1.3 inches (33 mm). The length chosen should be the same as with other types of rock bolts, and installed with the same spacing.

The stabilizer is installed with the same drill used to make the hole. Split Set stabilizers are commonly installed with jacklegs, stopers, jumbos and automatic bolting machines. Almost any hydraulic drill, or any percussive air drill with a bore of 2-5/8 inches (66 mm) and operating at 90 psig (6 bar), will have sufficient impact.

SS-33 drivers Standard	Shank size Inches	(mm)	Weight Lb.	(kg)	Comm. No.

Long-nose	1	(25)	2.2	(1.0)	90325507

Typical long-nose and short-nose drivers

Typical rope-threaded driver

SS-33 driver tools

A simple driver tool adapts the drill for easy stabilizer insertion. One end fits the tube; the other fits the drill chuck or drill steel.

All genuine Split Set driver tools are made of high-strength heat-treated alloy steel, designed for long life, and precision-made for the proper fit.

For jackleg or stoper insertion, a long-nose or short-nose driver tool may be used. The short-nose tool is also used for driving an SS-33 Split Set utility hanger inside an installed SS-33 Split Set stabilizer.

Rope-threaded drivers are available to fit drill steel for jumbos and bolters, and for long reach with jacklegs and stopers.

SS-33 utility hangers

Split Set utility hangers are available in 18 and 24-inch (46 and 61-cm) tube lengths to support light loads such as cables, vent tubing, and pipes.

Also, utility hangers can be driven inside installed Split Set stabilizers, by aligning the hanger slot with that of the stabilizer. This permits easier installation of mesh, after the ground is secured by the stabilizers.

SS-33 utility hangers					
Length In.	(mm)	Weight Lb.	(kg)	Comm No.	
Standard

SS-33 installation and pull testing

Bit selection and drilling

To select the correct drill bit diameter for meeting the recommended initial anchorage of 3 to 6 tons, drill several holes with bit diameters ranging from 1-3/16 to 1-5/16 inch (30 to 33 mm). Drill each hole at least 2 inches (5 cm) longer than the bolt length. Number each hole and record the bit size. (In soft ground, a bit may drill a hole larger than its diameter. In hard abrasive ground, the hole may be the same diameter as the bit.)

Drive into each hole an SS-33 Split Set stabilizer fitted with a pull collar and spacer as shown. Record the driving time for each stabilizer. After insertion, observe the amount of slot closure inside each stabilizer.

SS-33 pull collar and spacer set	Weight lb.	Weight (kg)	Comm. No.
	0.4	(0.2)	90320888

To determine anchorage, perform a pull test (page 4). Align the pull tester with the stabilizer, and pressurize it until the stabilizer slips in the hole.

Watch to be sure that it is actually the stabilizer that has slipped. When building up the pull load on the stabilizer, various adjustments may occur such as realignment of the tester housing, bearing plate settling, or localized rock crushing. These must not be mistaken for tube slippage.

Once the bolt has slipped in the hole, pressurize the tester pump until the bolt slips again. The same pull load should cause subsequent slippage.

Interpreting test data

After the above pull tests are completed, draw two graphs:

(a) Anchorage versus bit diameter.

(b) Anchorage versus driving time.

Use the first graph to determine the correct bit size for your particular ground condition. As the bit wears, the hole will become smaller and friction will increase until the bit is replaced or the drill can't drive the bolt completely.

Use the second graph to establish correct driving time required for this ground and bolt length. With a given bit, drill, bolt length, rock characteristic and constant pressure, insertion time will be proportional to initial anchorage.

It's important to establish this data for use in later spot checks, to assure that proper installation techniques are still being used.

(a) Anchorage versus bit diameter

(b) Anchorage versus driving time

Hex nut	0.3	(0.1)	95084778

SS-33 pull test equipment

The pull tester consists of two assemblies: the hydraulic portion which includes the cylinder, gage, pump, hose and adapter; and the mechanical portion which includes the claw, housing, U-shaped bushing, spindle and nut.

With the bushing removed, the claw can be slid over the pull collar which has been installed with the stabilizer. When the housing and cylinder are raised, the bushing can be inserted between the nut and the cylinder. The nut is then tightened to take up slack.

The pump is then actuated to raise cylinder pressure, pulling the stabilizer slightly out of the hole through the bearing plate.

Maximum gage reading at slip indicates the holding force. The device can be used for slip loads up to 12 US tons (10.9 metric tons).

Application Engineering Service

The Split Set stabilizer is a unique rock stabilization and support system.
It interacts with the rock differently from other rock bolts. For this reason, the Split Set Group offers a free application engineering service to assist you in the selection of the proper Split Set configuration for your needs. We will also assist in determining the best way to use your existing equipment for the job, the best drilling procedure, and appropriate tools and accessories for your equipment and space limitations.

We urge you to take advantage of this service. Our sales representative will be pleased to make the arrangements.

SS-39 installation and pull testing

Bit selection and drilling

To select the correct drill bit diameter for meeting the recommended initial anchorage of 3 to 6 tons, drill several holes with bit diameters ranging from 1-3/8 to 1-1/2 inch (35 to 38 mm). Drill each hole at least 2 inches (5 cm) longer than the bolt length. Number each hole and record the bit size.

In soft ground, a bit may drill a hole larger than its diameter. In hard abrasive ground, the hole may be the same diameter as the bit.)

Drive into each hole an SS-39 Split Set stabilizer fitted with a pull collar and spacer as shown. Record the driving time for each stabilizer. After insertion, observe the amount of slot closure inside each stabilizer.

SS-39 pull collar and spacer set	Weight lb.	(kg)	Comm. No.
	0.4	(0.2)	90320854

To determine anchorage, perform a pull test (page 4). Align the pull tester with the stabilizer, and pressurize it until the stabilizer slips in the hole.

Watch to be sure that it is actually the stabilizer that has slipped. (When building up the pull load on the stabilizer, various adjustments may occur such as realignment of the tester housing, bearing plate settling, or localized rock crushing. These must not be mistaken for tube slippage.)

Once the bolt has slipped in the hole, pressurize the tester pump until the bolt slips again. The same pull load should cause subsequent slippage.

Interpreting test data

After the above pull tests are completed, draw two graphs:

(a) Anchorage versus bit diameter.

(b) Anchorage versus driving time.

Use the first graph to determine the correct bit size for your particular ground condition. As the bit wears, the hole will become smaller and friction will increase until the bit is replaced or the drill can't drive the bolt completely.

Use the second graph to establish correct driving time required for this ground and bolt length. With a given bit, drill, bolt length, rock characteristic and constant pressure, insertion time will be proportional to initial anchorage.

It's important to establish this data for use in later spot checks, to assure that proper installation techniques are still being used.

Domed bearing plate

Split Set domed bearing plates uniquely combine high strength with light weight, and are integral parts of the Split Set system. Plates meet ASTM F-432-95 standards for Grade 3 plates where applicable, providing a load capacity of 15 tons (13.7 metric tons) with minimal deflection.

Domed bearing plate

Installing the SS-46 stabilizer

The SS-46 tube has a nominal outside diameter of 1.8 inches (46 mm). The length chosen should be the same as with other types of rock bolts, and installed with the same spacing.

The stabilizer is installed with the same drill used to make the hole. Model SS-46 Split Set stabilizers are commonly installed with jumbos. Almost any mounted percussive or hydraulic drill will have sufficient impact power for installing SS-46 stabilizers.

SS-46 drivers	Thread size Inches (mm)	Weight Lb. (kg)	Comm. No.
	1-1/4 (32)	4.4 (2.0)	90322448
	1-1/2 (38)	4.4 (2.0)	90322496
	T-38 (38)	5.0 (2.3)	90322587

Special tools are available on request.

Typical rope-threaded driver

SS-46 driver tools

A simple driver tool adapts the drill for easy stabilizer insertion. One end fits the tube; the other fits the rope-threaded drill steel.

All genuine Split Set driver tools are made of high-strength heat-treated alloy steel, designed for long life, and precision-made for the proper fit.

SS-46 utility hangers

Split Set utility hangers are available in 18 and 24-inch (46 and 61-cm) tube lengths to support light loads such as cables, vent tubing, and pipes.

18 (457)	3.1 (1.4)	90322645
24 (610)	4.1 (1.9)	90322652

SS-46 installation and pull testing

Bit selection and drilling

To select the correct drill bit diameter for meeting the recommended initial anchorage of 6 to 9 tons, drill several holes with bit diameters ranging from 1-5/8 to 1-3/4 inch (41 to 45 mm). Drill each hole at least 2 inches (5 cm) longer than the bolt length. Number each hole and record the bit size.

In soft ground, a bit may drill a hole larger than its diameter. In hard abrasive ground, the hole may be the same diameter as the bit.

Drive into each hole an SS-46 Split Set stabilizer fitted with a pull collar and spacer as shown. Record the driving time for each stabilizer. After insertion, observe the amount of slot closure inside each stabilizer.

SS-46 pull collar and spacer set	Weight lb.	Weight (kg)	Comm. No.
	0.5	(0.2)	90321647

To determine anchorage, perform a pull test (page 4). Align the pull tester with the stabilizer, and pressurize it until the stabilizer slips in the hole.

Watch to be sure that it is actually the stabilizer that has slipped. (When building up the pull load on the stabilizer, various adjustments may occur such as realignment of the tester housing, bearing plate settling, or localized rock crushing. These must not be mistaken for tube slippage.)

Once the bolt has slipped in the hole, pressurize the tester pump until the bolt slips again. The same pull load should cause subsequent slippage.

Interpreting test data

After the above pull tests are completed, draw two graphs:

(a) Anchorage versus bit diameter.

(b) Anchorage versus driving time.

Use the first graph to determine the correct bit size for your particular ground condition. As the bit wears, the hole will become smaller and friction will increase until the bit is replaced or the drill can't drive the bolt completely.

Use the second graph to establish correct driving time required for this ground and bolt length. With a given bit, drill, bolt length, rock characteristic and constant pressure, insertion time will be proportional to initial anchorage.

It's important to establish this data for use in later spot checks, to assure that proper installation techniques are still being used.

(a) Anchorage versus bit diameter

(b) Anchorage versus driving time

SS-46 pull test equipment

The pull tester consists of two assemblies: the hydraulic portion which includes the cylinder, gage, pump, hose and adapter; and the mechanical portion which includes the claw, housing, U-shaped bushing, spindle and nut.

With the bushing removed, the claw can be slid over the pull collar which has been installed with the stabilizer. When the housing and cylinder are raised, the bushing can be inserted between the nut and the cylinder. The nut is then tightened to take up slack.

The pump is then actuated to raise cylinder pressure, pulling the stabilizer slightly out of the hole through the bearing plate.

Maximum gage reading at slip indicates the holding force. The device can be used for slip loads up to 20 US tons (18.2 metric tons).

Application Engineering Service

The Split Set stabilizer is a unique rock stabilization and support system.
It interacts with the rock differently from other rock bolts. For this reason, the Split Set Group offers a free application engineering service to assist you in the selection of the proper Split Set configuration for your needs. We will also assist in determining the best way to use your existing equipment for the job, the best drilling procedure, and appropriate tools and accessories for your equipment and space limitations.

We urge you to take advantage of this service. Our sales representative will be pleased to make the arrangements.

Nothing contained in this brochure is intended to extend any warranty or representation, expressed or implied, regarding the products described herein. Any such warranties or other terms and conditions of sale of products shall be in accordance with International Rollforms' standard terms and conditions of sale for such products, which are available upon request.

Mesh

Welded Wire Mesh

- to ASTM A185 specifications
- wire to ASTM A82 specs (75,000 psi tensile)
- minimum weld shear strength (lbs) = 35,000 x wire cross sectional area (in^2)
- ends flush cut for safer handling
- available galvanized
- T = 4 (0.232"), 6 (0.192"), 8 (0.160"), 9 (0.144") and 10 (.0128") gauge
- W = 48" to 96" wide
- L = 48" to 24' long sheet or to 100' long roll
- S = 4" x 4" spacing typical but variable (as shown)

Chainlink Mesh (Frost Fencing)

- galvanized to ASTM A392 specifications
- T = 6 (0.192"), 9 (0.144"), 11 (0.120") and 12 (0.106") gauge
- W = 4', 5', 6', 7', 8' and 10' wide
- L = rolls 25', 50' and 100' long
- S = 2", 2½" and 3" opening size

Expanded Metal Mesh

- carbon steel to ASTM A1011 specifications
- up to 4x stronger than welded wire mesh at joints
- available galvanized
- T = 12 gauge (0.106")
- W = 4', 5' and 6'
- L = 4' to 10'
- S = 3" x 6" opening size

Gabion Mesh

- to ASTM A975 specifications
- galvanized
- weight = 0.365 lbs/ft^2
- T = 11 gauge (0.120")
- W = 2m (79") or 3m (118")
- L = 30m (99')
- S = 3.25" x 4.5" opening size

Custom sizes available on request

Formed Mesh

Mesh Channels
For construction of shotcrete barricades and fill fences

- mesh to ASTM A185 specifications
- wire strand to ASTM A82 specifications (75,000 psi tensile minimum)
- minimum weld shear strength (lbs) = 35,000 x wire cross sectional area (in^2)
- ends flush cut for safer handling
- T = 6 gauge (0.192")
- H/W = 3" x 3, 6" x 7.5", 7.5" x 9"
- L = 10'
- S = 4" x 4" spacing

Mesh Retainers
For construction of soil retaining walls

- mesh to ASTM A185 specifications
- wire strand to ASTM A82 specifications (75,000 psi tensile minimum)
- minimum weld shear strength (lbs) = 35,000 x wire cross sectional area (in^2)
- ends flush cut for safer handling
- available galvanized
- support struts hold mesh at 80° angle
- T = mesh and support struts 4 gauge (0.225")
- H/W = 18" x 18", 18" x 22", 18" x 24" and 20" x 22"
- L = 10'
- S = 4" x 4" spacing

Custom sizes available on request

Shotcrete Mesh Panels

Shotcrete Mesh Panels are constructed with black or galvanized mesh and burlap cloth. Stiffeners are incorporated for three-dimensionable stability. The panels can be various sizes depending on application. They are lightweight and can be cut-to-shape with small bolt-cutters. When Shotcrete is applied to the panels, the result is a durable wall, which is resilient to close proximity blasting.

Advantages

- Fast and easy to erect
- Non-corrosive if galvanized mesh is used.
- Concussion-resistant

Uses

- Construction of walls for lunchrooms
- Utility rooms
- Building bulkheads
- Protective wall for shaft areas

Installation

- Install grouted dowels on 2-4' centers around perimeter of proposed wall
- Tie 1/2" rebar to the dowels and form a grid of approximately 2-3' squares
- Tie the Shotecrete Mesh Panel forms to the rebar grid using tie wire. The rib stiffener of the panel is then tied to the rebar. The panels must be butted together and wire tied about every foot. Panels can be easily trimmed to conform to tunnel of drift irregularities using ordinary bolt-cutters.
- Apply Shotcrete through rebar grid.
- Can also be attached to existing beams on structures.

‘Gun Quip’ Wall & Support System

- Shotcrete panel
- ventilation walls - temporary or permanent.
- fireproof underground work shops and offices.
- provides rock support with rock bolt installation
- protective reinforcing around elevators and shafts.
- extra protection on walls and roofs near expensive machinery or electrical substations.
- comes complete with backing or plain
- manufactured under ASTM A02

panel side view

Technical wire specifications

- ASTM 510 wire composition
- ASTM A82
- wire size 14 gauge (WO.5)
- nominal diameter - wire diameter
  0.080" (2.032 mm). Specify wire diameter.
  0.081" +.001" (2.0574 mm + .0254 mm)
- Tensile
  maximum: 130,000 psi (896 MPa)
  minimum: 110,000 psi (758 MPa)

Polymesh

DYWIDAG Polymesh is comprised of high tenacity yarns, woven into a stable interlocking grid structure and then coated with PVC for protection during installation.

Polymesh is used for longwall recovery mats as well as rib and roof control. Longwall recovery mats are fabricated and assembled to mine-specifications.

- Light weight - reduces cost and handling time.
- No sharp edges, reducing injury hazard associated with chain link and welded wire.
- Conforms easily to the roof or ribs due to the multifilament yarn design.
- Stronger than other polymer grids: Since the longitudinal and transverse members are crossed and independent, there is less ripping out at the intersections than with other polymer grids.
- Both FRAS and Non-FRAS available (FRAS - Fire Resistant and Anti-Static))

Polymesh is available in rolls made to custom length. The typical roll lengths are 30 m, 50 m and 100 m.The width also can be customized to specific needs but common are 1.25 m and 2.5 m with 5 m being the maximum width.

DSI Grades	Tensile strength (ASTM-D4595)					Minimum aperture size		Weight (ASTM-D5261)	
	MD	XMD	MD	XMD	ultimate				
	at 2% strain[1]		ultimate						
All Polyester	lbs/ft		kN/m		elongation	inch	mm	oz/yd²	g/m²
55/55	440	440	55	55	18×23%	1.30	33	12	375
55/55	440	440	55	55	18×23%	2.40	60	12	375
80/80	650	650	80	80	18×23%	1.25	31	15	500
80/80	650	650	80	80	18×23%	2.40	60	15	500
200/80	1,600	650	200	80	18×23%	1.25	31	23	780
200/200	1,600	1,600	200	200	18×23%	1.05	26	38	1288

MD = machine direction, XMD = Cross Machine Direction
[1] 2% strain is equivalent to 10" convergence given 10ft unsupported span during shield recovery.

Polymer Mining Grid

DSI Polymer Mining Grid is an alternative to weld wire mesh products and can be used as a supplemental support structure between roof/rib bolts in any underground mining and or tunneling operation.

It is corrosion resistant and is especially applicable to any screening project when it will need to be "mined through" such as for pillar wrapping or for pilot tunnels. It is also especially useful in corrosive environments.

GEOGRID D TYPE

Straps (Mats)

W-Strap (Mat)

- T = 12, 14, 16 gauge
- W = 5" to 13"
- L = 54" to 240"
- C = hole size/spacing to customer specs

Rock Bolt Strap

- A36 material (36,000 psi yield)
- T = 12 gauge to ¼"
- W = 4" to 8"
- L = 48" to 120"
- C = hole/slot size/spacing to spec

Expanded Metal Mesh Strap

- 1008 material (30,000 psi yield)
- T = 8 gauge (0.164")
- W = 15"
- L = 88.5"
- deburred for safer handling

Welded Wire Mesh Strap

- to ASTM A185 specifications
- T = % gauge (0.306")
- W = 12"
- L = 84" and 108"
- S = 4" x 4" spacing

Custom sizes and/or galvanizing available on request

Roof Channel

Description

- 2 material grades - A36 and 65000psi minimum yield
- Length and hole spacing - to customer specifications
- Width - nominal 5-1/2 inches
- Thickness
  T-2 - minimum 0.100 inc
  T-3 - minimum 0.125 inch
  T-4 - minimum 0.145 inch
  T-5 - minimum 0.165 inch

Design Features

a) holes punched on the sides for hanging cables and ventilation materials

b) channel ends have the corners rounded - such reducing sharp corners and prevent cuts to the miners hands and backs in low coal

Bearing Plates (washers)

Flat Plate - for General Use

- minimum A-36 material (36,000 psi yield)
- A = 4" to 12" square
- B = ⅛" to 1½" thick
- C = hole diameter as required
- bent corner, grout slots & keyholes available

Domed Plate - Use with Anchornuts, Cable Grips or Spherical Seat Washers

- minimum A-36 material (36,000 psi yield)
- A = 5", 6", 8" and 12" square (rect 4" x 6")
- B = ¼" or ⅜" thick
- C = hole diameter as required

Friction Bolt Plate - for Use with Friction Stabilizers

- minimum A-36 material (36,000 psi yield)
- A = 6" square
- B = FB-33 & FB-39: 3/16" thick; FB-46: ¼" thick
- C = FB-33: 36mm (1 7/16") diameter
  FB-39: 41mm (1 ⅝") diameter
  FB-46: 48mm (2") diameter

Embossed Plate (Donut plate)

- minimum A-36 material (36,000 psi yield)
- A = 6" and 8" square
- C = 13/16" to 1⅛"
- available in Gr. 2 or Gr. 3 rating

Push-on-Plate - for installing Screen/Mesh (Threaded Bolts and OMEGA-BOLT® Rockbolts)

- heat treated to HRC 45 minimum
- A = 5" square
- B = 0.068" thick
- C = ⅝", ¾" and ⅞" available
- magnetic installation tool available

T-Dome Plate - for use with T-Dome Rock Bolts

- minimum A-36 material (36,000 psi yield)
- A = 4", 5" & 6" square
- B = ¼" thick
- C = ⅞" diameter

6" and larger plates meet or exceed ASTM F432 Grade 2 specifications for deflection
Custom sizes and/or galvanizing available upon request

Conventional Header Plate

- minimum A-36 material (36,000 psi yield)
- A = 6"
- B = 10" and 16"
- C = grade 2 and 3
- D = hole diameter as required

Low Profile Header Plate

- minimum A-36 material (36,000 psi yield)
- A = 6"
- B = 16"
- C = grade 2 and 3
- D = hole diameter as required

8 x 12 Header Plate

- minimum A-36 material (36,000 psi yield)
- A = 8"
- B = 12"
- C = grade 2 or grade 3
- D = hole diameter as required

T-Channel Plate

- minimum A-36 material (36,000 psi yield)
- A = 4"
- B = 9"
- C = grade 2 and 3
- D = hole diameter as required

Shotcrete (Spider) Plate (Black & Galvanized)

Description

DSI shotcrete anchor plates are constructed specifically for use with rock bolts and shotcrete. Reinforcing bar is custom bent and welded to conventional rock bolt anchor plates.

Plates are 5" x 5" x ¼", 6" x 6" x ¼" or ⅜". Hole size can be from ⅞" to 1½". Rise on spider can be made to any height required for depth of shotcrete.

Advantages

- Fast and easy to use.
- Greatly improves “punching” shear of shotcrete.
- Provides enlarged bearing area for higher load carrying capacity.

Where to Use

Any areas where bolting precedes shotcreting, especially in poor rock conditions, where improved bearing capacity of the ground support is desirable.

Dimensions	Center Hole	Form	Weight
5" × 5" × 1/4"	1.2"	Flat	4.5 lbs
6" × 6" × 1/4"	1.2"	Flat	6.4 lbs
5" × 5" × 3/8"	1.2"	Flat	9.6 lbs

Custom sizes available upon request

Installation

1. Install DSI shotcrete plates in the same manner as conventional plates.
2. Apply shotcrete to the rock surfaces and ensure the plates and rebar wings are embedded at least 38 mm (1½").

Materials

Plate material Grade A-36 (36,000 psi) meets or exceeds ASTM F432 deflection criteria. Rebar meets ASTM A-615 and CSA G30.18M specs.

Butterfly Plate

Length x Width	Thickness	Hole Diameter	Net weight black	Net weight galv.
300 × 278 mm 12 × 11 inch	1.9 mm	50 mm = 2 inch	2.87 lbs	2.95 lbs
400 × 278 mm 15.75 × 11 inch	1.9 mm	50 mm = 2 inch	3.73 lbs	3.83 lbs

The butterfly plate is a light-weight plate with a large surface area. It is used as an intermediate plate to increase the surface coverage of a bolt.

- DSI Butterfly plates feature both longitudinal and transverse V-shaped deformations for added strength and greater ability to conform to irregularities in the rock surface.
- The deformed design renders a greater strength, placing the perimeter of the Butterfly Plate in tension.
- User friendly rounded corners.
- Can be used with both flat and domed plates (up to 150mm, 6 in^2)
- Butterfly plates are can be placed directly to the rock surface or used with Welded Steel Mesh.
- Butterfly plates are supplied with slots for supporting of light service lines.
- Corrosion protection may be provided by hot-dip galvanizing the finished plate or by using pre-galvanized material.

Product Code(s)	
12 × 12" black	BUTT300S USA
12 × 12" galv.	BUTT300GS USA
12 × 16" black	BUTT400SWA
12 × 16" galv.	BUTT400GS

Packaging

Butterfly Plates are tied with wire clips and palletized.

Surface Control Plates

23" and 19"

General Information

- the 23" diameter is "special" order
- the 19" diameter is stock production
- all plates have the "rolled edge" to provide for safe handling
- large diameter plates for surface control
- these plates are to be used in conjunction with a roof bolt and roof plate

23" Description

- 23" diameter with a 1⅜" center hole
- available in a variety of mill thicknesses from 0.022" to 0.050" cold rolled or coated steel

19" Description

- 19" diameter with a 1" center hole
- 19" diameter with a 1⅜" center hole
- available in a variety of mill thicknesses from 0.022" to 0.050" cold rolled or coated steel

Scaling Examination Task Assessment

Trainee: _____ _____
(Print Name) (Signature)

Location: _____ **Date:** _____

1. The Legislation states that during scaling operations:

(a) Secondary work in the area may continue as usual.
(b) No other work activity shall be conducted in that worksite that may hinder or interfere with the scaling procedure.
(c) Only facemen and rockbolters are required to scale because they are the ones first in contact with fresh rock surfaces.
(d) A scooptram is the best device for sounding ground because it can hit the rock much harder than a scaling bar.

2. While scaling:

(a) Ear muffs and plugs must be worn to protect the worker's hearing from the sound of nearby loud equipment.
(b) Only ear muffs should be worn.
(c) No loud equipment should be running; as these impair the worker's ability to properly sound the rock.
(d) Only ear plugs should be worn.

3. Safety glasses, head, hand, and foot protection:

(a) Should not be worn, as they impair the worker's ability to sound the rock.
(b) Should be worn at all times while scaling.
(c) Are intended for those working in the forestry industry and do not apply to miners.
(d) Make the worker look silly and are not intended to be used.

4. Making and keeping the underground workplace safe from loose by scaling:

(a) Is the responsibility of the mine manager, mine captain and shift bosses.
(b) Is an activity to occupy workers when there's nothing else to do?
(c) Is a waste of time?
(d) Is a necessary and ongoing task and the responsibility of all people working underground?

5. Areas that are secured with rock bolts or screening:

(a) Are permanently safe from loose and never require scaling.
(b) Only require scaling once every five years or after a large rock burst.
(c) Must be inspected and scaled, just like any other area.
(d) Only need to be scaled if your shifter tells you to.

6. A scaling bar should be:

(a) Of the proper length to safely reach the rock being scaled.
(b) In good condition: straight and not too dull.
(c) Any one that you can find. Size and condition don't matter; they all work the same way.
(d) answers (a) and (b)

7. Ground should be scaled.

(a) From good ground to bad.
(b) From the bottom up.
(c) As quickly as possible.
(d) Only if you have time

8. A safe retreat must be maintained while scaling.

(a) Only if practical to do so.
(b) But is not required if worker has more than two years' experience.
(c) During night shift.
(d) At all times. This allows the worker to move out of the way if loose falls or throws scaling bar towards him/her.

9. When scaling, a *safe bed* for loose to fall on.

(a) Refers to an area where material scaled down can safely fall and not roll or slide onto the worker or cause any other injury or damage. A safe bed should be recognized before scaling down any piece of loose.
(b) Is a made-up word that is used to trick new miners? Most experienced miners know that there's no such thing and just laugh when you talk about it.
(c) Is only required when scaling from a scissor-lift or other elevated platform.
(d) Is another way of saying *a bench in a lunchroom*?

10. Pieces of loose which cannot be safely scaled down.

(a) Probably will never fall, and can be left as they are.
(b) Must be chiseled down with a stoper.
(c) Are never found at the Brucejack Project, and so are not of any concern to those writing this test.
(d) Must be roped off to prevent access, and must be reported to supervision so that arrangements can be made to secure the ground by other means such as blasting.

11. Loose ground can always be recognized by.

(a) Glancing at it as you drive underneath.
(b) Labels which are painted on by the engineering department.
(c) The 'drummy' sound it emits when struck directly and firmly with the end of a scaling bar, contrasted by the high-pitch 'ting' sound of a scaling bar striking solid ground.
(d) Checking geology drawings of the area and using these to identify any problems with the rock.

12. Scaling bars of proper length and in good condition must be kept.

(a) Easily accessible while in the work area, and at the entrance to the work area at the end of the shift.
(b) At the shaft station so that they will not be lost or damaged.
(c) In as best condition as possible by minimizing usage.
(d) For special jobs only, such as prying large machine parts from each other, or for use by the millwrights in the crusher.

II-D. Procon Safe Operating Procedures for Raise Climber Raising

SUBJECT: ALIMAK RAISE MINING BRUCEJACK UND-DRI-004		PROJECT: BRUCEJACK
EFFECTIVE DATE: JUNE 11, 2017	REVISION DATE: JUNE 26, 2020	PREPARDED / REVISED BY: JASON LI / NIGEL HOLMES

PURPOSE

To establish mandatory requirements for safe and responsible working standards for Alimak Raise Mining. This standard was created to provide consistent and safe operating procedures, for all employees and supervisors, and to comply with Procon Mining and Tunnelling standards, and relevant provincial/territorial mining regulations.

SCOPE

All activities related to Alimak Raise Mining. This includes set up, advancement and emergency procedures.

This procedure applies to all employees, including independent contractors of Procon Mining and Tunnelling.

PERSONAL PROTECTIVE EQUIPMENT

This includes hardhat with reflective stripes, steel toed boots, safety glasses, reflective stripes on outer wear, W65 self-rescuer, 5-point harness, lanyards (self-retracting lifelines), gloves and double hearing protection.

TOOLS AND EQUIPMENT

All gear related to Alimak raise mining: Rails spacer etc., ground support, survey equipment, raise laser, paint, scaling bar, low frequency 2 way radios for communication, glow sticks, air horn, and Ocencos.

RESPONSIBILITY

Site Superintendent is responsible for:

- Ensuring personnel comply with this procedure and that it is maintained.

Mine Supervisors are responsible for:

- Implementing this procedure.

All Alimak Raise Miners are responsible for:

- Being aware of and practicing this procedure, in addition to satisfying themselves of the following:

Have I done my pre-operational check?

Is my equipment/machine in good working condition?

What could fall or roll onto me?

Do I have a clear view of the area?

Is my ventilation sufficient?

Have I checked my work areas for other workers?

Is it safe to start drilling?

Site Safety Coordinator is responsible for:

- Monitoring the implementation of this procedure.

PROCEDURE

- Miners will get prints from Engineering/Survey.
- Check status of work done on previous shift.
- Proceed to Alimak nest to assess work area and perform pre-op inspections on Alimak.
- Ensure that adequate ventilation is provided to all workers in raise/headings. The supervisor will check at the start of every shift for gases and again during the shift.

1.0 ALIMAK MINING

1.1. Setup and Operating

- Only personnel trained and authorized are permitted to setup, maintain, and operate the raise climber.
- Ensure all guide rails have been adequately installed to the rock face and raise climber has been assembled correctly and is properly installed onto the guide rails.
- Check all hose reels are secured anchored and check all fittings/connections/whip-checks. Remove all oil off fittings/connections.
- Inspect all fittings/connections at the automatic air/water central to ensure all is in proper working condition. Check oil level in lubricator.
- Ensure all pathways are clear of obstructions and guide rails are clear of any debris.
- Install and extend guide rails as mining progresses; Ensuring proper expanding bolts are utilized (If poor ground is encountered, utilize longer expanding bolts). Spacers are to be used when the distance between the guide rail and rock face are more than 4” (100mm).
- Ensure trap-door and cage door are closed properly before ascending or descending in the cage. Personnel are to only be transported in the cage; unless maintenance is required on the guide rails.
- Ensure proper signage is in place at the bottom of the raise/workings (“Men Working Above”)

1.2. Scaling/Face Prep

- Proper face preparation and scaling shall be done prior to start of work and after every round.
- Scaling of the face and walls shall be done from under the safety roof on the working platform.
- Wash/clean misfires/bootlegs free and clear of explosives with a non-sparking copper blow pipe.
- Scaling bars of proper length shall be used

1.3. Drilling

- Inspect and check all equipment, hoses, fittings/connections are in good working condition.
- Check air and water lines are flowing freely and clear of obstructions.
- Ensure the stoper/jackleg footing is secure
-

1.4. Loading

- Only personnel trained and authorized as per BC regulations are permitted to handle explosives.
- Remove any materials or equipment that are not being used in the loading of explosives.
- The vehicle used to transport explosives shall meet the British Columbia HSRC requirements listed in 8.4.2 (Vehicle Requirements) and 8.4.3 (Transport of Detonator).
- There will be no smoking while handling, transporting and loading explosives.
- Ensure ventilation is sufficient.
- Clean out and measure all holes to be loaded; mark and have holes re-drilled as required.
- Explosives (daybox) shall only be transported on the raise climber when the face is ready to be loaded.
- If any explosives are believed to be defective, DO NOT USE. Remove from area for proper disposal and contact supervisor.
- Using a proper loading rod, place the booster (as required) and detonator at the designated location in the hole and fill with packaged emulsion (ensuring to adequate tamp each stick of emulsion to ensure hole is filled).
- Once loading has been completed, the blast may now be tied as per the design. Ensure all connections are secure and clear of any water or debris.

1.5. Clearing Gases

- Blasting gases must be cleared from the workings following a blast and prior to resuming work in the raise.
- Access to the automatic header must be maintained in a fresh-air area.

- Open all bypass lines for both water and air to allow a mist to form at the face. The resulting positive pressure will wash and force gases down the raise.
- Check gas levels. Continue to clear gases if gases levels have not reached a safe working level.
- Once gases have cleared, close all bypass valves at the central and notify Shifter once gases have cleared noting the time.

1.6. Scaling/Face Prep

- Following a blast, the fresh face and walls must be scaled of any loose prior to extending the guide rails to reach the face with the raise climber.
- Final scaling of the face and walls must be done under the safety roof. If the distance between the platform and rock wall exceeds 150mm (6”) safety wire and safety railing must be installed.
- Do not scale any large pieces of loose onto the working platform.

1.7. Installing Ground Support

- Ensure to have the latest ground support requirement plans for the raise
- Check to have the correct and competent drill bits, rock bolts, screen, pins, etc. A minimum length of 600mm (3 feet) shall be installed for each round.

2.0 EMERGENCY RESPONSE FOR ALIMAK

- Two (2) Ocencos to be carried with Alimak crew at all times.
- Raise crew will notify if an emergency is occurring by dropping glow sticks.
- One (1) of the two-way radios will be with Alimak crew at all times and the second radio will be located in the nest. Location of the nearest Femco must be noted by the Alimak crew.
- If there is an emergency in the mine and contact with the Alimak crew is required, turn the air off/on/off/on/off slowly in 5 second intervals to let workers know someone is trying to contact them. Then blast the air horn which will signal the Alimak crew to pick up the 2-way radio. (Both low frequency radio and air horn will be located in the nest).
- Communicate with Alimak crew what the problem is.
- **Turn air back on so raise miners can retreat back to nest.**
- A remote activated stench system will be set up at the raise to alert workers of a Code 1 emergency.
- Alicab will be located in a safe and secure area readily available and operational if needed.

2.1 ALI-CAB RESCUE PROCEDURE

In the event that the raise climber breaks down and workers cannot get back to the nest the following procedures must be followed:

- The crew will contact shiftboss or mechanical via Femco.
- Explain the situation and what type of assistance is required (personal injury, mechanical)
- The crew will be advised that personnel and equipment will be travelling up the raise to provide assistance via Femco or radio.
- Mine personnel trained in the operation of the Ali-cab will report to the raise
- Mechanic will remove the stop block to allow the Ali-cab to travel up the raise.
- Install 1" air hose to the header of the Ali-cab (stored in the marked crate)
- Take 2 extra Ocenco's up on the Ali-cab.
- Test run the unit. If all is functioning correctly, load the required tools, parts or emergency equipment onto the Ali-cab and proceed up the raise.
- Upon reaching the disabled climber, contact workers and begin to access the climber.
- Once the necessary repairs have been completed and the raise climber is operational, both units shall return to the nest and a thorough mechanical inspection must be completed.
- If it is a medical emergency, secure scene and make area safe. Treat life threatening injuries and bring injured worker down to nest for transport to surface.

All government mine regulations and company standards must be followed.

The Procon Shift Supervisor and the Procon Project Manager are responsible for implementing and enforcing this procedure. All Procon personnel are to follow this procedure.

II-F. Sample Planned Inspection Form

ProconSAFE
~beyond compliance

PLANNED INSPECTION

Inspection Performed By: Rod Wood Title: Shifter

Site: Brucejack Project (Job #484) Date: Feb 9/18 Shift: **D/S** **N/S**

1. This inspection will be performed **once per rotation** by each of the following personnel:
   - Front Line Supervisor: Shift Boss, Supervisor, Master Mechanic, or Lead Hand, both dayshift and nightshift

2. Place a check mark in the appropriate box in the "Ratings Columns" opposite the area / item being evaluated. If the area / item "Requires Action" classify the identified hazard & allocate sequential hazard letter, either A, B or C. (see table below for letter classifications)

3. Any item requiring "Immediate Action" must be dealt with immediately without delay.

4. After the Inspection form is completed; the form is to be forwarded to the Corporate Safety Office in Burnaby, BC via email - burnabysafety@procongroup.net or fax – 604.291.8292

Hazard Class

A - Any condition/practice likely to cause permanent disability of life/body part and/or loss of structure, equipment, or material.

B – Any condition/practice likely to cause serious injury/illness or property damage that is disruptive but less severe than class "A".

C – Any condition/practice likely to cause non-disabling injury/illness or non-disruptive property damage.

RATINGS COLUMN

Priority Guide **A-** Require immediate action. **B-** Requires action within 3 days **C-** Requires action within 15 days		Not Applicable	Requires Action	Acceptable	Excellent	Class A,B,C
1. Workplace Entrance						
A	Housekeeping		✓			
B	Warning signs in place (brake test before entering portal)			✓		
C	Road Conditions (surface portal entrance)			✓

PLANNED INSPECTION – ACTION ITEMS

Inspection Performed By: Rod Wood Title: Shifter

Site: Brucejack Project (Job #484) Date: Feb 9/18 Shift: D/S N/S

Items that are identified during the inspection process that require attention are transferred to the Action Item Sheet. Identify the item by writing the corresponding identification number and letter from the inspection checklist in to the designated column below. Then transfer the Hazard Class to the designated column and explain the hazard.

Item # (i.e. 8C)	Hazard Class (A, B, C)	Give a brief description outlining the concern you have identified	Responsibility Assigned	Date By:	Date Corrected	Super -visor Initial
1	A	Old vent on ground	Rod Wood	Feb 10 2018	Feb 10 2018	RW
5	C	No water in 1335 Refuge	Rod Wood	Feb 9 2018	Feb 9 2018	RW

III. Pretium Safety and Ground Control Documentation

III-A. SOP Underground Incident Command Plan

III-B. Rock Bolt Anchor Pull Test Data Sheet

III-C. Sample Geotechnical Inspection Memos

III-A. Pretium Underground Mine Emergency Response Plan

PRETIVM		BJ-OHS-SOP-008 Underground Incident Command Plan	
Owner: ERT Coordinators	**Approver**: H&S Manager	**Revision Number**: 6.0	**Creation Date**: 05/15/2017 **Revision Date**: 04/20/2020

Objective

The Underground Incident Command Plan will describe the actions taken by personnel in the event of any underground issue, emergency, or crisis to ensure:

- Our people are protected against injury or loss of life;
- The potential for asset loss is mitigated;
- Our reputation is protected;
- Damage to the natural and social environment is minimized;
- The community's interests are considered;
- Business continuity and recovery are assured; and
- Legal issues are considered.

In the event of a crisis we must be able to:

- Manage the crisis effectively and professionally, so that we may provide the necessary support and care to all involved personnel, protect the environment, and minimize the impact on our operations and business;
- Help the news media focus on known facts and our positive actions;
- Maintain public and shareholder confidence in our ability to effectively manage the crisis situation; and
- Continue to run the business effectively and efficiently during the course of the crisis.
- This manual has been designed to establish an effective management structure and process that will be readily prepared to support the Underground Incident Command Team, Emergency Response Teams, and Incident Management Teams in dealing with the crisis and to manage the associated sensitive communications issues in the first few critical hours of a crisis situation and the business continuity support thereafter.

If we can achieve these objectives, we will meet our goal of protecting and caring for the people impacted by our activities, as well as protecting the environment and our company's assets. We will also maintain the company's reputation during the crisis and our ability to inspire public confidence in our operations in the future.

Scope

The Underground Incident Command Plan describes the actions to be taken by personnel in the event of an emergency or crisis at the Brucejack Mine Site.

Health, Safety & Reclamation Code of BC

- 3.7.1 – Mine Emergency Response Plan
- 3.7.2 – Mine Rescue, Underground
- 3.4.2 (1)(i) safe work procedures, emergency response plan

Definitions

- MERP – Mine Emergency Response Plan
- PPE – Personal Protective Equipment

Background

Underground Incident Command Plan Context

The Underground Incident Command Plan will describe the actions taken by personnel in the event of any underground issue, emergency, or crisis to ensure:

- Our people are protected against injury or loss of life;
- The potential for asset loss is mitigated;
- Our reputation is protected;
- Damage to the natural and social environment is minimized;
- The community's interests are considered;
- Business continuity and recovery are assured; and
- Legal issues are considered.

In the event of a crisis we must be able to:

- Manage the crisis effectively and professionally, so that we may provide the necessary support and care to all involved personnel, protect the environment, and minimize the impact on our operations and business;
- Help the news media focus on known facts and our positive actions;
- Maintain public and shareholder confidence in our ability to effectively manage the crisis situation; and
- Continue to run the business effectively and efficiently during the course of the crisis.

This manual has been designed to establish an effective management structure and process that will be readily prepared to support the Underground Incident Command Team, Emergency Response Teams, and Incident Management Teams in dealing with the crisis and to manage the associated sensitive communications issues in the first few critical hours of a crisis situation and the business continuity support thereafter.

If we can achieve these objectives, we will meet our goal of protecting and caring for the people impacted by our activities, as well as protecting the environment and our company's assets. We will also maintain the company's reputation during the crisis and our ability to inspire public confidence in our operations in the future.

Underground Incident Command Plan Reviews and Updates

Reviews of the Underground Incident Command Plan should occur annually, and/or:

- Whenever enhancements have been identified during the normal course of business;
- Following a Brucejack incident/issue, to incorporate any lessons learnt;
- Whenever any lessons have been learnt from other sources (i.e. mock emergencies or desktop exercises);
- After an employee change which would have a significant effect on an emergency-related team's capability;
- Whenever details on stakeholder contact lists change; and
- After an organizational restructure.

Initial Emergency Actions

At any time, a worker may witness an incident and/or be called upon to assist with an underground emergency. Therefore, it is important that all workers at BruceJack Mine know and understand these initial emergency response procedures.

Declaring an Underground Emergency

CODE ONE – CODE ONE – CODE ONE on surface radio **Channel 2 Repeater 1 U/G radio Channel 1 (All Dispatch), FEMCO phone** or phone call to Dispatch **108** will initiate an emergency. The radio call is received

by Dispatch, at which time they will activate the Emergency Response Team (ERT). All areas at the Brucejack Gold Mine must stand down until told otherwise. Supervisors are responsible for ensuring no one is working in their area. All vehicles will go to the nearest pull out and remain there until instructed by Dispatch.

Refer to BJ-OHS-SOP-004 (Stench Gas Release) for instructions and locations to release the stench. Mill control room operator will be asked to release the stench in the VOK Portal and West Zone Portal.

ALL THE EMERGENCY PROCEDURES IN THIS

MANUAL ASSUME THE CALL HAS

BEEN INITIATED

It is critical to respond to any issue in an appropriate and timely manner to ensure it is resolved as soon as possible, and escalation to crisis level is avoided. When considering the level of activation, it is better to over-react and rapidly de-escalate. It is easier and usually more effective to scale down an over-reaction than it is to ramp-up an under-reaction.

Emergency Response Team (ERT) The Emergency Response Team acts quickly to ensure an effective immediate response to any Underground issue, emergency, or crisis.

The Emergency Response Team:

- Protects human life – provides appropriate medical response and mitigates life threatening situations while minimizing impacts on the environment and operations.
- Is responsible in responding to any level of underground emergency:
  - Fire;
  - Industrial emergencies;
  - Medical emergencies;
  - Technical rescue;
  - Chemical/environmental spills;
  - Mud rush/In rush of water; and
  - Natural disasters.
- Supports the Underground Incident Command Team during and after the initial response.

Underground emergencies requiring the ERT can be divided into two main categories; Toxic atmosphere (CCBA required) and non-toxic atmosphere (no CCBA required).

Toxic Atmosphere - A closed-circuit breathing apparatus (CCBA) is required and five ERT members constitute one Team. The ERT Coordinator remains on surface in the Control Room and the team of five complete the rescue work. The ERT Coordinator is the liaison person between the Team Captain and the Underground Incident Command Team. The ERT Coordinator is the sole individual responsible for the operation and direction of the Team(s).

- The Team of five (Team 1) is only allowed to enter the Underground Operations once they have tagged-in, received their brief from the ERT Coordinator, and Team 2 is physically in the mine rescue room.

Non-toxic Atmosphere – As many ERT members and equipment as required will respond to the scene.

Communication Flow (Incident Command Structure)

Underground Incident Command Activation

As soon as a significant Underground incident, crisis, or emergency is declared, Dispatch will activate the Underground Incident Command Communication System. The Underground Incident Command Team will muster in the Boardroom.

The activation process in an emergency is shown in the Incident Communication Flowchart (see below).

Activation of Mutual Assistance

In response to an emergency, the ERT Coordinator and the Incident Management Team (IMT) Leader will consider the need to request additional resources. The New Gold Mine from Kamloops may be called if necessary to assist in an emergency.

New Gold Mine Kamloops

- Call (250) 377-2770 Health and Safety Manager and state that the call is a mutual aid request for the Mine Manager (or designate)
- If a message is taken for relay (after hours) to the designated person, provide a telephone number that is guaranteed to be answered by the Operations Manager (IMT).

Only the Incident Management Team (IMT) Leader can formally request mutual aid.

Initial Actions

The first person to arrive at the Control Room is to commence preparing the room for the Underground Incident Command Team. As soon as the Underground Incident Command Team convenes, an initial team briefing should be held.

The Incident Commander facilitates the initial briefing. The objectives of this initial meeting are to:

- Introduce members and ensure understanding of their respective roles/responsibilities;
- Review key assignments;
- Brief members on the incident;
- Identify on-scene assistance needed by ERT;
- Identify issues;
- Provide objectives and establish priorities;
- Task members;
- Plan for the worst-case scenario; and
- Identify triggers to recognise escalation towards worst-case scenario;

All Underground Incident Command Team members should commence and maintain an ‘Individual Actions Log’ from activation until the completion of the post-crisis review. The individual actions log (hardcopy) is located in the applicable duty card manila envelope in the Control Room.

Underground Incident Command Team

In addition to Underground Incident Command Team members knowing and understanding their primary roles and responsibilities, it is important that they are familiar with all Underground Incident Command Team roles and responsibilities, as they may be required to fulfil these roles at any time (particularly during the early stage of activation).

Underground Incident Command Structure

The duty card checklist system helps to ensure an effective and timely response to a crisis by guiding team members through the specific activities required of their role on the Underground Incident Command Team. The duty card checklists also enable other employees to replace a designated team member when they are unavailable. Duty card checklists, for each role, are located on the wall in the Control Room in manila envelopes and within this manual.

Key Appointments

It is important to note that the Underground Incident Command structure is only a guide to the functions that may be required to effectively respond to an emergency. Depending on the incident's severity, some groups may only require one appointment to be filled, or may require multiple appointments fulfilling the same role. Similarly, if the situation deteriorates, then the Underground Incident Command structure may require supplementation or, conversely, if the situation improves, then elements of the structure may be 'stood down'.

Incident Commander (Duty Card Checklist #1)

The Incident Commander is responsible for management and decision making in relation to incident assessment and the on-going management of the Underground emergency response. The Incident Commander is the final decision maker in plan development, analysis, selection and execution.

Mine Rescue Coordinator/ERT Coordinator (Duty Card Checklist #2)

The Mine Rescue Coordinator is the ERT Coordinator or delegate senior ERT member and their primary duty is to synchronise the Emergency Response Team(s). The Mine Rescue Coordinator manages and coordinates the ERT while providing quality control and coordination with the Underground Incident Command Team.

The deployment and direction of the Emergency Response Teams is the sole responsibility of the Mine Rescue Coordinator and the proper chain of command must be followed.

Group Coordinators

Group Coordinators provide subject matter expertise to the Incident Commander in decision-making and provide the conduit for the Incident Commander to execute emergency response action plans. The Group Coordinators (Operations, Engineering, and Maintenance Coordinator) are responsible for forming task-oriented teams (if required) and managing those teams to support the overall Underground Incident Command response effort.

ERT Advisor/ Safety (Duty Card Checklist #3)

The ERT Advisor will direct teams from the fire hall and communicate with the ERT Coordinator in the Incident Command Room.

Operations Coordinator (Duty Card Checklist #4)

The Operations Coordinator manages the tasking and application of resources to resolve a crisis or emergency. This is achieved through the management of emergency response activities and by the development and implementation of an appropriate response plan. The Operations Group is led by the Operations Coordinator (Duty Card Checklist #3). The Operations Group includes:

- Underground Dispatch (Duty Card Checklist #7);
- Check-in Coordinator (Duty Card Checklist #8);
- Two (2) Check-in Assistants (Duty Card Checklist #9);
- Two (2) Entrance Guards (Duty Card Checklist #10).

The Operations Group's tasks are to:

- Determine the location and condition of all personnel Underground;
- Verify and ensure proper emergency notification has been activated (Stench, Radio);
- Maintain the communication link between the Dispatch, ERT, and the Underground Incident Command;
- Ensure the Incident Commander has complete situational understanding of an emergency event;
- Maintain records of all actions taken, activities and information;
- Ensure no personnel enter the underground operations;
- Provide subject matter expertise appropriate to the nature of the emergency to the Incident Commander; and
- Advise the Incident Commander of plan options, and assist the Incident Commander in decision making;

Engineering Coordinator (Duty Card Checklist #5)

The Engineering Coordinator is responsible for providing technical assistance to the Incident Commander. If required, the Engineering Coordinator can request a Ventilation Engineer, Ground Support Engineer, or other onsite subject matter expert.

The Engineering Coordinator tasks are to:

- Support the Incident Commander in managing the crisis;
- Provide copies of current ventilation plans. Review plans (utilizing overhead projector) showing mining areas, ventilation flows and controls, refuge stations, escape ways, explosives magazines, etc;
- Inform the Underground Incident Command Team of draw point locations where pre-loading of emulsion and/or ANFO exists;
- Provide technical assistance to the Incident Commander; and
- Maintain records of all actions taken, activities, and information.

Maintenance Coordinator (Duty Card Checklist #6)

The Maintenance Coordinator is responsible for providing any maintenance related issues to the Incident Commander. If required, the Maintenance Coordinator can request a Mechanical Supervisor, Electrical Supervisor, or other onsite subject matter expert.

The Maintenance Coordinator tasks are to:

- Support the Incident Commander in managing the crisis;
- Under the direction of the Incident Commander, identify and work to remedy any maintenance related issues;
- Provide technical assistance to the Incident Commander; and
- Maintain personal records of all actions taken, activities, and information.

Two Recorders (Duty Card Checklist #7)

The Recorder reports to the Incident Commander and is responsible for recording key information and events.

- Record key incident information on the status boards;
- Manage the flow of hard copy information and retain copies for a permanent log;
- Alert other Underground Incident Command members to major changes, issues and outstanding actions;
- Take digital photos of status boards before they are updated;
- Proactively monitor all communications and record pertinent points as they arise; and
- Document all personal actions and decisions in an individual log
- Second recorder will stay with dispatch and record all pertinent information and assist dispatch as necessary

Post Incident:

- Assist with the collection and filing of all documentation from all groups.

Technical and Administrative Support

In the event of an emergency, the Underground Incident Command Team can draw upon the support of employees to provide administrative and technical support and expertise as necessary. The type and scale of the emergency will determine the support required.

Underground Incident Command Team Training

Underground Incident Command Training will be provided for new members joining the team and desktop scenarios will be conducted quarterly.

Underground Incident Management Room

The Control Room is the focal point of the Underground Incident Management Team's emergency response. It is important that the Control Room is well-equipped and organised so the team is best positioned for effective decision-making, able to achieve optimal information sharing, and achieve the best possible outcomes in emergency response.

Activation Pack

The activation pack is a pre-prepared hard plastic case containing stationary supplies, notepads, and other items required upon Underground Incident Command activation. This pack is designed to assist members in fulfilling their duties and responsibilities. If items are used from the pack, team members must notify the ERT Coordinator to refill the contents.

Status Boards

During a crisis, a great deal of information is gathered by the Underground Incident Command Team. In order to accurately capture, display and record this information, standardised status boards located in the Control Room are available for use. These hard copy status boards are rolled up and located in the Control room. The status boards include: Incident Status Board, Event Log, Issues and Actions, and Casualty Information Board.

It is the responsibility of the Recorder to record the information on a status board if appropriate.

Management

The ERT Coordinator is in charge of the management of the Control Room. This responsibility commences well before the occurrence of an emergency event. The ERT Coordinator/ ERT Advisor is responsible for ensuring that the Control Room is stocked with the appropriate duty cards, status boards, copies of the Underground Emergency Response Plan, and other relevant collateral. Additionally, the Engineering Coordinator should monitor the serviceability of IT equipment, communications systems, and room amenity systems.

On standing down the Underground Incident Command Team (Code One is over), the ERT Coordinator is responsible for refurbishing all pre-prepared materials, such as duty cards and checklists, for use in a future event.

Managing Communication

Context

Throughout the period of emergency response, the Underground Incident Command Team is in control of the situation and actions that are occurring Underground and affecting Underground Operations. The success of the response will be determined by the way the Incident Commander manages information, plans, and executes with the direction of the Underground Incident Command Team.

Effective communication in a crisis is critical. An uncoordinated, ineffective response could not only damage the reputation of Pretivm Resources and the Brucejack Mine but also the future viability of the business.

The Incident Management Team (IMT) will manage communication with internal and external stakeholders, not the Underground Incident Command Team.

General Enquires

In the event that Incident Command Team Members or other employees are contacted by someone requesting information or comment about the incident, they should:

- Inform the person that they are not an authorised spokesperson, and as such, they are not in a position to comment.

Standing Down the Response

The Underground Emergency response ends when the ERT Coordinator states 'The Code One is Over' and the transmission is relayed through Dispatch.

Once the emergency response has ended, the Incident Commander will stand down the Underground Incident Command Team and return the Mine to normal operations. In their place, a Mine recovery team may be

required to take control of any Brucejack business recovery effort. On standing down the Underground Incident Command Team, the Incident Commander should detail the state of the business, the work achieved and the intent for the way forward.

Debriefing and Counseling

Debriefing is the process of drawing out lessons learned and imparting advice for improvement to and from engaged staff and priority stakeholders after an event. The Recorder will record the minutes and the information will be passed on to the ERT Coordinator.

Counselling is the provision of personal support and management to people who are exposed to potentially stressful environments or situations. This process is managed by the Human Resources Department (IMT) who may be supported by specialist external providers.

INCIDENT COMMANDER DUTY CARD

INCIDENT COMMANDER - **Checklist**		
☐	1)	In the event that there is an Underground CODE 1 **fire** emergency, it is critical that the Underground Emergency warning system is activated without delay, and that the accounting for personnel begins. These Three Actions must be taken FIRST before the Underground Incident Command Team musters: • Ensure the Main fan (WZ and VOK) Stench Gas has been released: • Only if required, have the electricians manually release the stench in the compressed airlines • Ensure Code One was called on all channels (Dispatch is responsible for this action); • Secure the UG tag-in board by placing a guard at the board. Non-fire emergencies require Code One call, and radio message to clear the ramp to the scene.
☐	2)	Ensure the Underground Incident Command Team positions are fulfilled: Operations Coordinator; Engineering Coordinator; Maintenance Coordinator; and Recorders. Required Phone Numbers: Main Camp Boardroom (UGIC) – 640 Boardroom (IMT) – 455 Tagboard – 675 U/G refuge 1335 – 676 Safety Training Room (IMT Alternate) – 699 Survey office (Check in – Alternate) – 484 Firehall – 444
☐	3)	Obtain a verbal briefing outlining the incident from the relevant Underground Team Captain and/or ERT Advisor (ext 444 Fire Hall).
☐	4)	Conduct an initial team brief and detail initial response priorities to the Underground Incident Command Team.
☐	5)	Start an individual log, document all personal actions and decisions. Ensure the Recorder has posted the status boards and is recording relevant information.
☐	6)	If the fire is in a heading with charged explosives (Operations Coordinator will confirm) and communicate this with the ERT Coordinator. The ERT Coordinator will instruct the ERT not to

		fight the fire.
☐	7)	In consultation with ERT Coordinator decide on a response plan for the Mine Rescue Team and whether or not to activate the Incident Management Team. Ventilation cannot be changed until the mine manager has approved changes and all personnel are accounted for. As well, everyone must be made aware of the ventilation change.
☐	8)	Determine staging areas for the extra people and traffic that are in the area effected by the code one.
☐	9)	Follow up and monitor assigned responsibilities.
☐	10)	Consult with ERT Coordinator and Mechanical Supervisor to determine if a mechanical inspection of any mobile equipment involved is required prior to calling the Code One over.
☐	11)	In consultation with the ERT Coordinator, decide when the incident is over. The ERT Coordinator will make arrangements for the “Code One Over” message to be relayed and broadcast. Dispatch will receive confirmation from the Incident Commander prior to broadcasting “Code one over”
☐	12)	Ensure all relevant information is entered in Incident Commander Log sheet.
☐	13)	At the conclusion of the incident, sign the Incident Commander log sheets.

Post Incident - **Checklist**		
☐	1)	Ensure the ERT Coordinator replenishes the Duty Card Packets.
☐	2)	Debrief the Underground Incident Command Team and provide feedback.
☐	3)	Confirm recommended changes to the Underground Incident Command Manual and other relevant documents have been completed (ERT Coordinator is responsible).

ERT COORDINATOR DUTY CARD

ERT Coordinator - Checklist		
☐	1)	Coordinate with Incident Commander and Underground Incident Command Team to plan the Mine Rescue Teams actions while underground. Required Phone Numbers: Main Camp Boardroom (UGIC) – 640 Boardroom (IMT) – 455 Tagboard – 675 U/G refuge 1335 – 676 Safety Training Room (IMT Alternate) – 699 Survey office (Check in – Alternate) – 484 Firehall - 444
☐	2)	Brief Mine Rescue Team 1 on incident and plan of action. When Team 2 is travelling to Underground, Team 1 will get under air. Once Team 2 enters the Underground surface building, Team 1 can commence with their rescue operation.
☐	3)	Record all actions and orders given to Mine Rescue Team in your action log. Record the time Team 1 enters the underground in the ERT Coordinator Logbook (Approximately 1 bar for every 1 minute Underground with the BG4). Check in every 15mins and record all air supply levels of the team.
☐	4)	Maintain contact with Mine Rescue Team while underground and provide direction as required. Always follow the Mine Rescue Principals in order: Safety of the team; Safety of the trapped/injured; Protection of mine property; Rehabilitation of mine property.
☐	5)	Consult with Incident Commander and Mechanical Supervisor to determine if a mechanical inspection is required prior to calling the Code One over.
☐	6)	Check with Incident Command on areas underground where pre-loading of emulsion explosives are located. **NOTE: Under no circumstances will the Mine Rescue Team fight fires in a heading with charged explosives**
☐	7)	Contact Incident Command to relay 'The Code One is over' once the final Team is finished.
☐	8)	Replenish incident command cards

Post Incident- Checklist		
☐	1)	Debrief with ERT members at the Fire Hall.
☐	2)	Follow-up with Incident Commander and Engineering Coordinator on the Underground Incident Command Team debrief. Gather notes and action items.

ERT ADVISOR DUTY CARD

ERT Advisor - Checklist		
☐	1)	Gather cap lamps, tag-in cards, and W65's for incoming teams.
☐	2)	Report to Dispatch (108) or ADMIN CH 1 (ERT CHANNEL) when ERT arrives at the Fire Hall (both Team 1 and 2).
☐	3)	Brief Mine Rescue Team 1 on incident and plan of action. When Team 2 is travelling to Underground, Team 1 will get under air. Once Team 2 enters the Underground surface building, Team 1 can commence with their rescue operation.
☐	4)	Contact ERT Coordinator via Channel 1 (ERT Channel) Required Phone Numbers: Main Camp Boardroom (UGIC) – 640 Boardroom (IMT) – 455 Tagboard – 675 U/G refuge 1335 – 676 Safety Training Room (IMT Alternate) – 699 Survey office (Check in – Alternate) – 484 Firehall - 444
Post Incident- Checklist		
☐	1)	Debrief with ERT members at the Fire Hall.
☐	2)	Follow-up with Incident Commander and Engineering Coordinator on the Underground Incident Command Team debrief. Gather notes and action items.
☐	3)	Collect all information from rescue and make any necessary changes to procedure.

OPERATIONS COORDINATOR DUTY CARD

Operations Coordinator - Checklist		
☐	1)	Record all relevant information in the Operations Coordinator log sheet.
☐	2)	Oversee all immediate needs of the Incident Commander.
☐	3)	Assign the following responsibilities: Check-in Coordinator – Name: Mine Entrance Guards – Names: West Zone portal guard: VOK portal guard: Office Entrance Guard(security) – Name: Door guard: Transportation Coordinator (not required unless operation is extensive) Transportation Coordinator name:
☐	4)	Confirm with ERT Coordinator to ensure the Underground Mine Rescue Team has been notified and all necessary radio calls have been made.
☐	5)	If applicable, barricade or post guards at the incident area to prevent any unauthorized access and remove all non-essential personnel.
☐	6)	Brief and keep the Incident Commander informed. This communication must include any area that has the potential for explosives.
☐	7)	Monitor assigned responsibilities.
☐	8)	Sign the Operations Coordinator log sheet and return to Recorder when emergency is over.

Post Incident - Checklist		
☐	1)	Participate in the post crisis review
☐	2)	Evaluate the effectiveness of the Underground Incident Management Team during the response and implement any necessary changes to the room or associated procedures

ENGINEERING COORDINATOR DUTY CARD

Engineering Coordinator - Checklist		
☐	1)	Set up personal work station. Required Phone Numbers: Main Camp Boardroom (UGIC) – 640 Boardroom (IMT) – 455 Tagboard – 675 U/G refuge 1335 – 676 Safety Training Room (IMT Alternate) – 699 Survey office (Check in – Alternate) – 484 Firehall - 444
☐	2)	Enter all relevant information on the Engineering Coordinator log Sheet.
☐	3)	Assign a Ventilation Engineer and provide instructions and support throughout the incident.
☐	4)	Provide copy of current ventilation plans. Review plans showing mining areas, ventilation flows and controls, refuge stations, escape ways, explosives magazines, etc.
☐	5)	Provide technical assistance to the Incident Commander.
☐	6)	Ensure main surface fans are operating as required.
☐	7)	Follow up and monitor all assigned responsibilities.
☐	8)	Sign the Engineering Coordinator log sheet and return to the Recorder when emergency is over.
Post Incident - Checklist		
☐	1)	Assist with the collection and filing of all documentation from all groups. Pass the information onto the ERT Advisor.
☐	2)	Participate in the post-crisis debrief.
☐	3)	Ensure allocated post-crisis follow-up actions are completed.

MAINTENANCE COORDINATOR DUTY CARD

Maintenance Coordinator - Checklist		
☐	1)	Assign Mechanical Supervisor and Electrical Supervisor, if required: Name of Mechanical Supervisor: Name of Electrical Supervisor:
☐	2)	Confirm that Stench at the main fans has been released (by radio). Only if required , check to make sure the stench gas has been released in the compressed lines.
☐	3)	Report to Incident Commander that stench has been released.
☐	4)	Under the direction of the Incident Commander, identify and work to remedy any maintenance related issues.
☐	5)	Discuss with the ERT Coordinator the need to have a mechanic inspect equipment involved in the incident prior to calling the Code One over.
☐	6)	Record relevant information in the Maintenance Coordinator log sheet.
☐	7)	Sign the Maintenance Coordinator log sheet and return to Recorder when emergency is over.
Post Incident - Checklist		
☐	1)	Participate in the post crisis review
☐	2)	Evaluate the effectiveness of the Underground Incident Management Team during the response and implement any necessary changes to the room or associated procedures
☐	3)	Provide a list of what equipment is locked out and/or need repair.

RECORDER DUTY CARD #1

Recorder - Checklist		
☐	1)	Set up personal work station and start recorder.
☐	2)	Record key incident information on the event log and/or the status boards (rolled up poster sheets located in the auxiliary room). This must include times.
☐	3)	Update the status boards and manage administrative functions.
☐	4)	Manage the flow of hard copy information and retain copies for the permanent log.
☐	5)	Assist the Incident Commander in record keeping.
☐	6)	Alert team members of major changes, issues and outstanding actions.
☐	7)	Take digital photos of status boards before they are updated.
☐	8)	Proactively monitor all communications and record pertinent points as they arise.
Post Incident - Checklist		
☐	1)	Assist with the collection and filing of all documentation from all groups.
☐	2)	Participate in the IMT post-crisis interview.
☐	3)	Assist with refurbishing the Incident Management Room back to a ready state.

RECORDER DUTY CARD #2

Recorder - Checklist		
☐	1)	Set up personal work station.
☐	2)	Record key incident information on the event log. This must include times.
☐	3)	Assist Dispatch in all aspects.
☐	4)	Manage the flow of hard copy information and retain copies for the permanent log.
☐	5)	Record all pertinent information from radio and telephone communication
☐	6)	Alert team members of major changes, issues and outstanding actions.
☐	7)	Take digital photos of information received
☐	8)	Proactively monitor all communications and record pertinent points as they arise.
Post Incident - Checklist		
☐	1)	Assist with the collection and filing of all documentation from all groups.
☐	2)	Participate in the IMT post-crisis interview.
☐	3)	Assist with refurbishing the Incident Management Room back to a ready state.

DISPATCH DUTY CARD

Dispatch - Checklist		
☐	1)	If an underground emergency is called on any UG channel, immediately relay the message without delay to Senior Management as per site extensions. Ch2 days Event: _____ Location of Event: _____ Person Reporting Event: _____ Injuries: _____ Required Phone Numbers: Main Camp Boardroom (UGIC) – 640 Boardroom (IMT) – 455 Tagboard – 675 U/G refuge 1335 – 676 Safety Training Room (IMT Alternate) – 699 Survey office (Check in – Alternate) – 484 Firehall - 444
☐	2)	If it is a medical emergency, inform all personnel on all underground channels to clear all ramps to the incident scene.
☐	3)	Monitor channel “all dispatch” and record any information in the Dispatch logbook.
☐	4)	If calls are received from a refuge station to report people present tell the caller that someone will contact them shortly. If the caller has information regarding the emergency record on log sheet. Relay information to Operations Coordinator.
☐	5)	Relay relevant information received from the UG channels to the Operations Coordinator.
☐	6)	When requested, provide any information on the location of personnel or equipment to the Operations Coordinator.
☐	7)	Record relevant information on Dispatch log sheet.
Post Incident - Checklist		
☐	1)	Participate in the IMT post-crisis interview

CHECK-IN COORDINATOR DUTY CARD

Check-In Coordinator - Checklist		
☐	1)	Start your Check In Coordinator log sheet. Required Phone Numbers: Boardroom – 640, Boardroom (IMT) – 455, Tagboard – 675, U/G refuge 1335 – 676 Safety Training Room (IMT Alternate) – 699, Survey office (Check in – Alternate) – 484, Firehall - 444
☐	2)	Designate the West Zone shop area and VOK Portal entrance as the muster area.
☐	3)	Assign one of the people mustering to direct, supervise & monitor personnel in the muster area. Instruct them to ensure all personnel remain in the muster area. Name: _____ Assign one Tag Board Check-In Assistant to oversee/guard the tag board. Instruct them not to let anyone remove a tag from the board until all workers are accounted for and the Check-In Coordinator has given approval. Tag board check in assistant:_____
☐	4)	Install the TAG BOARD “NO ENTRY” BARRICADES around the tag board to prevent persons from entering the TAG BOARD area.
☐	5)	Assign two Refuge Station Check-In Assistants. Designate each person specific refuge stations. Distribute refuge station records accordingly.
☐	6)	Delegate two Check-In Assistants to sit in the Shifter’s office to start call ins. Refuge Station Check-In Assistants #1: Refuge Station Check-In Assistants #2: Ensure the Check-In Assistants have their appropriate Refuge Station Check-In sheets (#1 and #2). The refuge stations are split up between Assistants to increase efficiency.
☐	7)	Monitor and direct the activities of the Check-In Assistants and UG Office muster area.
☐	8)	Provide a list of personnel accounted and unaccounted for and any Refuge Stations that were not contacted to the Operations Coordinator
☐	9)	Inform Operations Coordinator when all personnel are accounted for.
☐	10)	Release persons in the UG Offices muster area once the Code One is over.
☐	11)	Ensure all relevant information is entered in Check-In Coordinator log sheet, sign, then give to the recorder.
Post Incident - Checklist		
☐	1)	Participate in the IMT post-crisis interview

CHECK-IN ASSISTANT DUTY CARD

Check In Assistant - Checklist		
☐	1)	Use the REFUGE STATION RECORD sheets to phone all assigned refuge stations and record the name, employer/company name, refuge location, and condition of all personnel. Repeat the names to the refuge station attendant for verification. Ensure to include the refuge station attendant name. If a refuge station cannot be contacted by phone inform the Check-In Coordinator who will provide a radio. Attempt to contact the refuge station on radio channel 1, 2, and 3. Use a separate sheet for each refuge station and circle the refuge station location at the top of the sheet. Required Phone Numbers: Boardroom – 640, Boardroom (IMT) – 455, Tagboard – 675, U/G refuge 1335 – 676 Safety Training Room (IMT Alternate) – 699, Survey office (Check in – Alternate) – 484, Firehall - 444
☐	2)	After all refuge stations have been contacted once, take the REFUGE STATION RECORD to the tag board and read the names one at a time to the Tag Board Check in Assistants. The Tag Board Check in Assistant will flip the tags as you read them. The Refuge Station Check in Assistant will mark an X in the column on the REFUGE STATION RECORD beside the person's name to indicate their tag has been flipped. Once all names have been read from the Refuge Station Check in Assistants list, compile a list of people not accounted for and notify the Check-In Coordinator.
☐	3)	Return to designated office and contact all the refuge stations again for any new arrivals. Repeat process at tag board of confirming names and flipping tags.
☐	4)	Provide a list of personnel unaccounted-for to the Check-In Coordinator.
☐	5)	Follow all directions from the Check In Coordinator.
☐	6)	Record all relevant information in the Refuge Station Check in Assistants Log sheet
☐	7)	Sign the Refuge Station Check in Assistant's Log sheet and return all paperwork to Recorder when emergency is over.
Post Incident - Checklist		
☐	1)	Attend the incident post-crisis review

ENTRANCE GUARD DUTY CARD

Entrance Guards - Checklist		
☐	1)	There are two locations that need to be guarded: West Zone Portal; VOK Portal; The Operations Coordinator will brief the two individuals with all pertinent information.
☐	2)	Obtain communications radio (Channel 2 RPT 1) and proceed to your designated location.
☐	3)	Record all relevant information in the Entrance Guard log sheet.
☐	4)	Position yourself, or vehicle: West Zone Portal - In a location that allows visual surveillance of the portal without being exposed to mine exhaust flow. VOK Portal - In a location that allows visual surveillance of the portal without being exposed to mine exhaust flow.
☐	5)	Stop anyone: West Zone Portal – Who attempts to enter the mine via the West Zone Portal. Contact Operations Coordinator to advise. VOK Portal – Who attempts to enter the mine via the VOK Portal. Contact Operations Coordinator to advise.
☐	6)	Identify anyone who exits the mine via the West Zone or VOK Portal. Contact the Operations Coordinator (Channel 2) to request transportation or first aid treatment of personnel exiting the mine.
☐	7)	Follow all directions from the Operations Coordinator.
☐	8)	Duties are not relieved until the Operations Coordinator instructs you to leave your post.
☐	9)	Sign the entrance guard log sheet and return to Underground Incident Command Team when emergency is over.

Appendix B - Response Procedures

Protocols

The aim of the following protocols is to describe the issues/actions to be considered during a particular type of Underground Emergency. Many of these actions are the responsibility of the Underground Incident Command Team and/or the Incident Management Team (IMT). All incidents are different and these generic protocols will have to be adapted accordingly. It is the role of the Incident Commander to agree the optimum way to manage and respond to any incident to save and safeguard life, protect the environment, and minimize damage property.

Major Underground Explosion

BUSINESS ISSUES

- Safety of personnel;
- Evacuation, reception, support of personnel;
- Infrastructure impacts; and
- Company image/reputation;

IMMEDIATE ACTIONS

The ERT Coordinator will ensure the following is completed:

- Team 1 (five ERT members) will conduct a bench test of their BG4 breathing apparatus at the ERT hall and prepare the underground ambulance for response.
- Team 2 (five ERT members) will conduct a bench test and be backup for Team 1. Team 2 will respond in the rescue truck.
- Team 3 (five ERT members) will standby and backup Team 2 if dispatched.

Teams must have a full back-up Team before responding to major unexpected explosions.

MAINTAINING THE RESPONSE

- Underground Incident Command Team assembles and emergency duty card checklist system is implemented;
- The Incident Management Team (IMT) will be contacted and respond to this type of emergency. Mine Manager makes the call;
- Medic prepares to receive casualties and ambulance and other vehicles capable of transporting injured.
- Important information required if achievable from initial reports, area supervision, drawings and/or from refuge station witnesses:
    - Are there any injuries and number of people not accounted for?
    - The source and location of the explosion if known.
    - Are there any hazards in the area (open holes, explosives, fuel, vehicles not secured, equipment parked on an incline, fire beyond control, air lines, power cables, electrical sources)?
    - Location and status of auxiliary fans and mine services.
- The Underground Incident Command Team obtains adequate information from all possible resources on the nature of the incident;

- The safety of the ERT is number one priority and the first consideration is the route of travel and when and where to report back;
- If possible the team should always be directed to travel in the best air or on the intake side of the explosion and potential fire;
- The ERT Coordinator, with input from the Underground Incident Command Team, is to complete the initial response plan;
- Team 1 receives directions from the ERT Coordinator. Team 1 tags-in and is on standby until given the go ahead to enter the mine from the ERT Coordinator.

Team 1 explores the mine and reports back information as required to the ERT Coordinator.

- Key information (signs of smoke or fire, gas readings, ventilation direction/speed, personnel encountered and injuries;
- Information is transmitted by Team 1 and gathered by the Underground Incident Command Team for continued review of response requirements.

If a fire has been ignited by the explosion and the fire can be easily extinguished, the ERT will extinguish the fire. The casualties in the area will be treated and transported to a refuge.

If the fire is beyond control of the team and there are casualties in the area, the injured will be evacuated prior to extinguishing the fire.

If the fire is not extinguished in Team 1's time frame, Team 2 will be deployed to continue the work.

- This will require Team 3 to bench and prepare to be Team 2's back up. Team 1 will clean up and rest.
- The three teams can cycle two (2) hour shifts under CCBA.
- Once it has been determined that the fire extends beyond 6 hours, the Incident Management Team will activate mutual assistance.

Once the fire is out and patients are taken to safe area and treated, the Underground Incident Command Team will derive a plan to check all areas of the mine to ensure that the smoke is clear and safe to evacuate the people from the refuge stations to surface.

- Derive plan to check all effected ventilation areas;
- Fire watch stationed at fire location ensuring it stays out (CCBA required);
- ERT completes all checks and safety routes as required;
- Underground Incident Command gives approval to release refuge station occupants and to report to surface.

Gas tests will be conducted behind any seals to determine that there are no longer signs of combustion before tearing down and rehabilitation of the affected area.

- Underground Incident Command requests gas sampling from ERT under CCBA until all signs of combustion are no longer present;
- Once safe, request ERT to remove seals under CCBA and vent out smoke;
- Tape off area for incident investigation;
- Equipment salvaged and area rehabilitated.

Equipment/Personnel Down Open Hole

IMMEDIATE ACTIONS

The ERT Coordinator will ensure the following is completed:

- ERT respond with mine rescue vehicle and underground ambulance;
- ERT will tag-in and respond underground;

- ERT Coordinator will be on scene and in communication with the Underground Incident Command Team via radio.

MAINTAINING THE RESPONSE

Important information required from initial reports, area supervision, mine plans, and or from eye witnesses:

- Number of personnel involved;
- Location and depth of fall;
- Equipment involved;
- Any other known hazards;
- Obtains adequate information from all possible resources on the nature of the incident and commence a response plan; and
- Underground Incident Command Team may requests a radio message sent out to have all underground personnel report to refuge stations for a head count and stand by for assistance.

Rescue methods from the top of the hole:

- Lower rescuer(s) and basket utilizing MPD system with 540 safety belay. If patient is uninjured, lift with harness. If the patient is injured, utilize basket. Anchor could be ground supports, scoop bucket or any other suitable available anchor.
- If the hole is small in diameter, utilize tripod system.

Rescue from the bottom:

- Requires mucking out and pulling with LHD equipment to get the victim out. Utilize rope and rigging horizontally to pull patient out;
- May require vehicle extrication tools to cut and lift materials out of the way.

Precautions to consider:

- Loose materials around the open hole;
- Loose on the walls and back above the open hole. (Clear all loose before entering the hole and without knocking materials down onto patient on descent);
- Wedged equipment in the hole begins to fall further. (Rescuers and victims attached to safety lines at all times).

The ERT Coordinator and designated senior mining person on scene will coordinate with the Underground Incident Command Team to support, remove materials, and equipment for the rescue of trapped person(s).

Once the area is safe to proceed ERT members will extract victims utilizing rescue tools and equipment as required. Once rescued, the casualties will be transported to the Medic's clinic.

Ground Fall (Personnel Trapped or Missing)

IMMEDIATE ACTIONS

The ERT Coordinator will ensure the following is completed:

- ERT respond with rescue truck and underground ambulance;
- ERT will tag-in and respond underground; and
- ERT Coordinator will be on scene and in communication with the Underground Incident Command Team via radio.

MAINTAINING THE RESPONSE

Important information required from initial reports, area supervision, mine plans, and or from eye witnesses:

- Number of personnel involved;
- Location and size of ground fall;
- Equipment involved (buried, pinned, stuck); and

- Any other known hazards;

This type of incident may require an assessment in the field involving the ERT Coordinator, Underground Ground Support Engineer, Shift Supervision, and/or Senior Mine Personnel to determine requirements at the scene. The area will be required to be made safe before responding.

Depending on the extent of the ground fall, the rescue could take a relatively short period of time with minimal equipment (rescue airbags) or several hours/days (requiring ground support and removal of several tons of material). If the fall is extensive, a designated Senior Mining Engineer on scene will coordinate with the Underground Incident Command Team, mining operations, and rescue teams to support, remove materials, and equipment for the rescue of trapped person(s).

- Once the area is safe to proceed ERT members will extract victims utilizing rescue tools and equipment as required; and
- Once rescued the victims will be handed over to the Medic.

Injured Underground Personnel

IMMEDIATE ACTIONS

The ERT Coordinator will ensure the following is completed:

- Location of the incident is safe from toxic hazards (i.e. oxygen depletion, gases, etc.). This will be conducted with a MX4 gas detector;
- ERT respond with underground ambulance and rescue truck;
- ERT tags-in and enters portal to scene without delay;
- ERT on scene. ERT Coordinator will be on scene and in communication with the Underground Incident Command Team via radio.
- Extrication and treatment completed;
- ERT transports injured to medic's Clinic;
- Incident scene taped off for incident investigation.

MAINTAINING THE RESPONSE

Investigation required and hazards eliminated before work commences.

Underground Fire (Fixed or Mobile)

BUSINESS ISSUES

- Safety of personnel;
- Evacuation, reception, support of personnel;
- Infrastructure impacts; and
- Company image and reputation.

IMMEDIATE ACTIONS

The ERT Coordinator will ensure the following is completed:

- Team 1 (five ERT members) will conduct a bench test of their BG4 breathing apparatus at the ERT hall and prepare the rescue truck for response.
- Team 2 (five ERT members) will conduct a bench test and be backup for Team 1. Team 2 will respond in the UG ambulance.
- Team 3 (five ERT members) will standby and backup team 2 if dispatched.

Teams must have a full backup Team before responding to any toxic atmosphere emergency.

MAINTAINING THE RESPONSE

- Underground Incident Command Team assembles and emergency duty card system is implemented;

- If the event is serious, the Incident Management Team will be contacted and respond to the emergency.
- Medics prepare to receive casualties and ambulance and other vehicles capable of transporting injured.
- Important information required (area supervision, information from refuge station witnesses);
- Are there any injuries and number of people not accounted for?
- The source and location of the fire if known;
- Are there any hazards in the area (open holes, explosives, fuel, vehicle not secured, unit parked on an incline, fire beyond control, air lines, power cables, electrical sources);
- Location and status of auxiliary fans and mine services;

The Underground Incident Command Team utilizes the duty card checklist system and gathers all available and pertinent information to aid in an initial response plan for the ERT.

- The safety of the team is number one priority and the first consideration is the route of travel and when and where to report back;
- If possible the team should always be directed to travel in the best air or on the intake side of the fire;
- The ERT Coordinator with input from the Underground Incident Command Team will complete the initial response plan; and
- Team 1 receives directions from the ERT Coordinator. Team 1 tags-in and is on standby until given the go ahead to enter the mine from the ERT Coordinator.

Team 1 explores the mine and reports back information as required to the ERT Coordinator.

- Key information (signs of smoke or fire, gas readings, ventilation direction/speed, personnel encountered and injuries); and
- Information is transmitted by Team 1 and gathered by the Underground Incident Command Team for continued review of response requirements.

If the fire is beyond control of the team, a plan of attack will be planned and agreed upon by the Underground Incident Command Team and ERT Coordinator.

Precautions when fighting mobile equipment or fixed structure fires:

- Burning tires may explode (If this is the case the team must retreat out of the area until the tires have exploded);
- Service airlines may burst. Teams will be required to maintain distance from service air lines;
- Energized power cables, transformers, substations, etc (power may be required to be turned off at the heading or substation);
- Poor visibility for ERT members. Teams may not be able to safely advance towards the fire if on the exhaust side;
- Hydraulic oil, diesel fuel, and motor oil on the equipment; and
- Loose created by the fire or if located in an unsupported area.

Methods of directly fighting the fire:

- Utilize hand held fire extinguishers;
- Utilize mine water services and water hose;
- Seal off the heading with muck and burlap to create a seal. Seal intake first if ventilation flows through;
- Erect light seal and fill with foam using high expansion foam generator; and
- If everyone is accountable and safe in refuge stations let fire burn out on its own. If the fire is beyond control of the team and there are casualties in the area the injured will be evacuated prior to extinguishing the fire.

If the fire is not extinguished in Team 1's time frame, Team 2 will be deployed to continue the work.

- This will require Team #3 to bench and prepare to be Team #2 backup. Team #1 will clean up and rest;
- The three teams can cycle 2 hour shifts under CCBA;
- Once it has been determined that the fire extends beyond 6 hours, the Incident Management Team will activate mutual assistance;

Once fire is out and patients are taken to safe area and treated, the Underground Incident Command Team will derive a plan to check all areas of the mine to ensure that the smoke is clear and safe to evacuate the people from the refuge stations to surface.

- Derive plan to check all effected ventilation areas;
- Fire watch stationed at fire location ensuring it stays out (CCBA required);
- ERT completes all checks and safety routes as required;
- ERT verifies all routes are safe to travel;
- Underground Incident Command gives approval to release refuge station occupants and to report to surface.

Gas tests will be conducted behind any seals to determine that there are no longer signs of combustion before tearing down and rehabilitation of the affected area.

- Underground Incident Command request gas sampling from ERT under CCBA until all signs of combustion are no longer present;
- Once safe, request ERT to remove seals under CCBA;
- Ventilate smoke (all personnel accounted for) ;
- Tape off area for incident investigation;
- Equipment salvaged and area rehabilitated.

Mud Rush or In Rush of Water

IMMEDIATE ACTIONS

Ensure all Underground employees are notified.

Important information required from initial reports, area supervision, Geotechnical services, and/or from eye witnesses:

- Is it safe to enter the mine and look for missing people?
- Is the mud rush contained to the level?
- At what rate is the water rising and last known elevation level?
- How many people are missing and last known location(s); and
- Any other known hazards.

Underground Incident Command obtains adequate information from all possible resources on the nature of the flooding and commences a response plan.

The ERT Coordinator will ensure the following is completed:

- ERT respond with mine rescue vehicle and underground ambulance to the portal area.

MAINTAINING THE RESPONSE

This type of incident requires careful assessments of dangers that may be encountered by rescue teams should people be unaccounted for and or are in need of help to evacuate the mine.

- ERT Coordinator and Underground Incident Command Team reviews rescue plan and makes final decision on route of travel and response;
- ERT Coordinator gives permission for Team 1 to enter and explore the mine for missing workers. Team 1 is only allowed to enter the Underground Operations once they have tagged-in, received their brief from the ERT Coordinator, and Team 2 is physically ready as backup;

- Mine rescue teams explore mine by safest route and reports conditions encountered on way to last known location of missing worker(s) provided it is safe to do so;
- Trapped or missing personnel extricated and transported to surface as soon as possible;
- ERT transports injured to First Aid room.

Vehicle/Equipment Interaction

IMMEDIATE ACTIONS

The ERT Coordinator will determine if there is a possibility of fire through communication with the caller or dispatch. If fire is present, the ERT will respond as Appendix 3.5 Underground Fire (Fixed or Mobile). If there is no possibility of fire, the ERT Coordinator will ensure the following is completed:

- ERT respond with underground ambulance and mine rescue vehicle;
- ERT tags-in and enters portal to scene without delay;
- ERT on scene. ERT Coordinator will be on scene and in communication with the Underground Incident Command Team via radio;
- Extrication and treatment completed;
- ERT transports injured to first aid room; and
- Incident scene taped off for incident investigation.

MAINTAINING THE RESPONSE

Other equipment that may be required in the event of mobile equipment/vehicle interaction:

- Scoop tram to remove muck if haulage truck involved, assist in a lift, or pull away equipment to reach victims;
- Loader with forks or basket;
- Maintenance vehicle with cutting torch to remove or cut away enforced steel that may be trapping victims.

WHAs designate habitats in which activities are managed to minimize their effect on the Identified Wildlife for which the area was established.
WAC	Wildlife Advisory Committee

1 PURPOSE

1.1 INTRODUCTION

This Mountain Goat Management Plan (MGMP) describes actions that are intended to mitigate potential effects on mountain goats during the Construction, Operations, Closure and Post-closure phases of the Brucejack Mine (the Mine), owned and operated by Pretium Resources Inc. (Pretium). It focuses on the management recommended for legislated Ungulate Winter Range (UWR), high quality summer habitat, unique areas (mineral licks; kidding areas), and areas of known persistent use within the wildlife Regional Study Area (RSA) particularly on the Mine footprint components and activities (Rescan 2013a). Unless otherwise indicated, measures described in the MGMP apply to all components for the life of the Mine. This plan is designed to be adaptive, effective, and achievable in both the short and long term, and will incorporate the activity details as they are developed with the Mine.

1.2 BACKGROUND INFORMATION

Mountain goat populations were surveyed in the RSA during the summers of 2010 and 2012, and the winters of 2011 and 2013, following provincial standards for aerial surveys standards (RIC 2002). These surveys reported 286 mountain goats in the RSA (Rescan 2013a). Furthermore, mountain goats were surveyed in 2017 following provincial standards for aerial survey standard during the summer and 298 goats were observed (ERM 2017). The mountain goat surveys in 2022 yielded detections of 325 goats in 84 groups from 12 survey unit (SU) areas (ERM 2023). Mountain goats were observed in all SUs including areas where no individuals were detected during the 2017 survey period (ERM 2023).

For winter habitat in the Brucejack area, aerial surveys indicate that, mountain goats prefer subalpine forest stands that provide a diverse range of arboreal and rooted plant forage adjacent to escape terrain. Tree and shrub cover on steep, rocky ledges offer thermal advantage during sunny weather (solar radiation) and during inclement stormy weather by providing cover from snow. Goats also prefer southerly aspects because snow accumulation tends to be lower and food can be found more readily (Wilson 2005). Natal and kidding habitats are generally smaller pockets of habitat located within and near winter ranges (Mountain Goat Management Team 2010, p. 11).

During summer, mountain goats move to higher elevations to exploit the newly emerged high-quality vegetation. Areas with abundant early seral stage vegetation (e.g., grasses and herbs) are preferred by mountain goats. Mountain goats also seek higher elevation habitat as it provides thermal relief during the warmest periods of summer. Mineral licks at various elevations receive annual use and are important for the local mountain goat population. They are used primarily during the summer to compensate for mineral deficiencies or imbalances in goats' diets (Ayotte, Parker, and Gillingham 2008).

The majority of goats recorded during baseline studies (Rescan 2013a) were observed in mid-elevation habitat generally below the treeline along the Bowser River and close to Bowser Lake in the winter, and in high-elevation habitat above the treeline near peaks associated with Sulphurets Creek, in the summer. These areas also have UWRs that were occupied by wintering goats in 2012. See maps in Appendix A.

The nearest occupied high quality mountain goat habitat to Mine infrastructure is beyond 3 km west of the Brucejack Mine Site on either side of Sulphurets Creek, well away from any mining activities. High quality mountain goat habitat was defined in the environmental assessment for the Mine as high, medium–high, and medium-rated habitat derived from habitat suitability modeling (Rescan 2013b). Baseline surveys indicated that the majority of goat observations occur in this high quality goat habitat (Rescan 2013a). Other areas of occupied high-quality mountain goat habitat within the Mine area include an area 1 km north of the Brucejack Access Road (BJAR) approximately mid-way between Knipple Lake and the Mine, and an area along the mountains north of Bowser Lake, beyond 3 km from the BJAR. Additionally, the nearest identified kidding habitat to Mine infrastructure is west of the Knipple Glacier, approximately 1 km away from the Knipple Glacier Access Road crossing. No mineral licks have been found near Mine infrastructure (see maps in Appendix A).

2 PERFORMANCE OBJECTIVES

The overall performance objectives of the MGMP are to:

- prevent disturbance and habitat loss to goats within designated and candidate UWR during the winter and within high-rated summer habitat during the kidding period;
- manage disturbance due to aircraft and helicopters through avoidance where possible and minimization where it cannot be avoided; and
- manage incidental mortality of mountain goats due to avalanche control procedures through pre-avalanche control surveys, herding of goats from avalanche paths, and delaying avalanche controls until goats clear the area.

This document provided direction for environmental managers mainly during the Construction phase of the Mine but also is applicable to the Operations, Closure and Post-closure phases. Mine-related activities of relevance to this MGMP include the construction of mining infrastructure, transmission line, camps and other early-stage facilities and activities associated with helicopter use, and avalanche control during all Mine phases.

3 SCOPE

The MGMP is applicable to Construction, Operations, Closure and Post-closure activities that require Mine-specific mitigation and monitoring. The MGMP provides the environmental personnel and construction crews with information that can be used to coordinate activities and avoid negative effects on mountain goats where possible and to mitigate effects where unavoidable. Site-specific mitigation and monitoring will be addressed through the following measures (Table 3-1):

1. Clearing Management for Mountain Goats (Section 5.1)
2. Aircraft and Helicopter Management for Mountain Goats (Section 5.2)
3. Avalanche Management for Mountain Goats (Section 5.3)

Table 3-1. Summary of Mitigation Measures Applicable to Mine Phases and Components

Mitigation Measure	Mine Phase	Mine Component
Clearing Management	Construction	Transmission Line
Aircraft and Helicopter Management	Construction; Operations	All Components
Avalanche Management	Construction; Operations; Closure	Mine Site, Access Road, Transmission Line

4 RELEVANT LEGISLATION, REGULATIONS, AND PERMITS

Mountain goats are protected legislatively by the provincial *Wildlife Act* (1996) and guidance for habitat management is provided by the provincial *Forest Regulation and Protection Act* (FRPA; 2002). Under the FRPA, areas that are important or critical to ungulates and sensitive wildlife may be designated as Ungulate Winter Ranges (UWRs) or Wildlife Habitat Areas (WHAs), and General Wildlife Measures (GWMs) may be used to manage forest and range practices for protection and conservation of the species (Mountain Goat Management Team 2010).

General Wildlife Measures established for UWRs and WHAs include regulations for primary forestry activity (defined under the Forest Planning and Practices Regulation to include tree clearing and access structure [road/trail] construction/maintenance), such as prohibiting road construction, timber harvesting or silviculture treatments within established buffers around UWR and/or WHA boundaries unless an exemption is provided. Schedule 1 - GWM order # U-6-002 identifies management measures and actions that can be carried out in the UWR in the Nass Timber Supply Area, Upper Portion of the Ningunsaw and Unuk watersheds within the Mine RSA.

The relevant best management practices that guided the development of this plan are summarized in the *Management Plan for the Mountain Goat in British Columbia* and *A Compendium of Wildlife Guidelines for Industrial Development Projects in the North Area, British Columbia* (Mountain Goat Management Team 2010; BC MFLNRO 2014). Procedures and protocols of the best management practices were incorporated in the clearing, aircraft and helicopter, and avalanche management actions for mountain goats in the following sections.

5 ENVIRONMENTAL PROTECTION AND MANAGEMENT

This section identifies the management and mitigation measures to facilitate protection of mountain goats as per the BC Mountain Goat Management team guidelines and GWM order #U-6-002 (Mountain Goat Management Team 2010). This includes consideration for clearing and pre-clearing surveys, and air-based activities. In addition, avalanche management is considered due to the potential of incidental mortality caused by avalanche control procedures.

5.1 CLEARING MANAGEMENT FOR MOUNTAIN GOATS

Most Construction Phase clearing for the Mine was completed between September 5 and November 1, 2015, within the timing window that is outside of periods identified as being sensitive for mountain goats. The southern-most section of the transmission line, as well as the preferred Bulk Emulsion Site are not within or in proximity to UWR habitat and were cleared in 2016 when it is snow-free. Clearing of the Knipple Transfer Area was also completed during autumn 2015, along with most of the clearing for the Bowser Aerodrome and camps, and locations where additional clearing was needed along the lower BJAR (km 0-58). Minor additional clearing for the Bowser Aerodrome and BJAR (mainly borrow locations) may be done later; however, these sites are not within or in proximity to UWR habitat. No clearing is needed at the Mine Site, as it is above treeline. Clearing management as described in the following section will therefore only be relevant in the unlikely event that additional clearing needs are identified for the Mine in the future.

Mitigation activities are determined by habitat type, season and the number of goats observed. If any winter clearing is planned in future, pre-clearing surveys will be conducted during winter when ground-based Mine activities are within 500 m of UWR habitat (Rescan 2013a, 2013b). If clearing is required within a UWR or within 500 m of UWR habitat during the sensitive period, an exemption permit application will be submitted by a Registered Professional Biologist. Work requiring helicopter or aircraft support will be conducted as described in Section 5.2, Aircraft and Helicopter Management.

All actions regarding mountain goat clearing management will be directed by qualified environmental personnel (either staff or consultant) with appropriate experience with ungulates in BC. The objective for surveys will be to conduct them as close to clearing as possible, with a maximum of 72 hours before clearing. The pre-clearing survey will survey for goats out to 2-3 km from the proposed clearing site, covering the area of mountainside defined by drainages unlikely to be crossed by goats. If a particular block of mountain side does not have goats, then the clearing teams are free to clear within 72 hours. If goats are found within 1.5 km of the clearing site: 1) a further pre-clearing survey will be conducted, 2) the site will be surveyed as the crews are being put out, or 3) the clearing schedule will be altered to clear that site later, following another pre-clearing survey. If the pre-clearing is conducted within 24 hours of clearing, and the area within 500 m of the clearing site is clear of goats, clearing can continue as planned. Vegetation clearing will be halted if goats are observed within 500 m of the clearing area during sensitive timing periods (i.e., winter – November 1 to June 14 for all goats, and May 1 to July 15 for goats with kids) until animals are outside the recommended threshold distance of 500 m.

If goats with kids are observed, additional surveys will be conducted, and mitigation implemented. Note that kidding is assumed to occur at mid to high elevation generally up-slope during the winter or

spring and goats are at high elevation during the summer or fall months. Table 5.1-1 summarizes the timing, habitat, triggers, and mitigation activities.

Table 5.1-1. Mitigation Activities for Mountain Goats during Vegetation Clearing

Timing	Habitat	Mitigation Activities
Winter (November 1 to April 30)	UWRs	The preferred option is to avoid activities within 500 m of UWR habitat during winter. If clearing is planned in these areas during winter, then conduct pre-clearing surveys and apply for an exemption permit. If goats are observed within a 500 m buffer of clearing, pause work until goats have moved outside of this buffer.
Summer (May 1 to July 15)	High-quality Summer Habitat – Kidding Areas	If goats with kids are observed between May 1 and July 15 within a 500 m buffer during clearing activities, pause work until goats have moved off. Avoid clearing activities within 2 km of confirmed natal/kidding areas. Pre-clearing surveys may also be conducted less than 72 hours prior to activity.
Spring/Fall (April to November	High-quality Summer Habitat – Mineral Licks	Avoid destruction of mineral licks. Minimize disturbance within 100 m of licks.
All Year	All Habitats	Vehicles accessing the Mine will be required to give the right of way to mountain goats observed on the road.

5.2 AIRCRAFT MANAGEMENT FOR MOUNTAIN GOATS

Mountain goats are potentially sensitive to noise and disturbance from development, particularly to helicopter disturbance, as well as other aircraft. Goats are vulnerable to disturbance during:

- winter (November 1 to April 30) in the low elevation forested areas that goats use during winter in designated UWRs; and
- kidding period (May 1 to July 15) in the high elevation alpine areas that goats use during kidding, summer, and fall.

The guidelines proposed by the province do not differentiate between types of helicopters. However, research and professional experience indicate that goats react at different distances to different types of aircraft. Goats typically react more strongly to larger, multi-rotor aircraft (e.g., Vertol, Chinook) that are louder than other helicopters, and larger helicopters with only two blades (e.g., Bell 205) that produce a distinct blade slap noise when descending (ERM unpublished data).

In contrast, goats typically react less strongly to smaller, multi-blade helicopters such as the Eurocopter A-star, which produces a “whine” rather than a blade slap sound. Choosing the appropriate helicopter should reduce the potential for disturbance to mountain goats at the site and allow the helicopters some small leeway in flying closer to goats if the circumstances require it (e.g., low ceiling).

During primary forest activities [i.e., clearing and access structure (road/trail) construction], mountain goat mitigation related to aircraft includes:

- As recommended by the province, maintaining 2 km horizontal setback from mountain goats where feasible and weather permitting. Also, maintaining 500 m vertical separation between helicopters and mountain goat habitat, weather permitting.
- Educating pilots as to the importance of avoiding and not flying towards mountain goats, particularly during important periods of the year such as kidding and winter.
- Disseminating established flight paths for camps and construction areas to all new pilots.

There is a general set of helicopter "behaviours" which, if followed, can significantly reduce the potential for mountain ungulates to be disturbed by helicopters. Goats typically have little defence against predators, except fleeing to escape terrain and they likely perceive helicopters as a predation risk. Thus, it is important to understand and have the helicopter "behave" in a way that does not startle or trigger this predation response.

General recommendations for pilots include:

- Avoid overflights of occupied goat habitat whenever possible (below suggested elevations of 500 m), including avoiding "flightseeing".
- If flying a helicopter that produces a heavy "blade slap" noise, avoid inducing this noise when overflying or adjacent to occupied goat habitat.
- If a pilot is aware that goats are on the opposite side of a ridge or mountain, avoid surprising goats by flying low over the ridge and suddenly appearing above them.
- Avoid triggering a goat's "chase response" by avoiding flying directly at goats. Helicopters flying tangentially to goats are perceived less as potential predators.
- Goats can become habituated to helicopters if the helicopters operate in a predictable and non-threatening manner. Wherever possible, use the same routes and elevations to and from camps and drills.
- Use topographic barriers to separate helicopters from mountain goats.
- Keep helicopters below mountain goats if feasible.
- Helicopters can drop off specialized work crews in goat habitat, but only when goats are not present within 500 m.

In the balance between operability and reducing disturbance to goats, for aircraft activities pilots are instructed to maintain the largest separation feasible from mountain goats. The ideal situation is >2 km. In some cases, it may not be possible to maintain >2 km separation with goats given that certain valleys may be less than 2 km wide, and seasonal low clouds may force helicopters into the bottom of valleys. Pilots avoid flying within 500 m of goats, even if that means that certain valleys are unpassable on certain days with low cloud. Pilots minimize any flights in the range of 500-1,500 m, to those that are absolutely necessary. Pilots do not conduct crew "tours" near goats. There are allowances for different topographies given the fact that the average width of valleys in NW BC is 1.5-2.5 km wide. Flight paths that consider observed goat use and occupation of habitat within the RSA are provided in

Appendix A. Air traffic is encouraged to use these paths to minimize disturbance during sensitive periods.

5.3 AVALANCHE MANAGEMENT FOR MOUNTAIN GOATS

5.3.1 Management Activities

Avalanche management is conducted in the winter during all Mine phases. Mountain goats occupy alpine areas with steep, rocky cliffs during the summer. During winter, mountain goats can occupy low elevation forested areas on southern slopes as well as habitat in or below areas prone to avalanches, including alpine areas above the BJAR, near Knipple Lake, and along the Knipple Glacier (Figure 5.3-1 and Appendix A). Avalanche management activities include management to avoid mortality or abandonment of habitats by mountain goats due to control induced avalanches.

Avalanche management procedures typically use helicopter deployment of explosives (Pretium 2018a, 2018b). This procedure requires the avalanche area to be clear and visible prior to deployment. However, Remote Avalanche Control System (RACS) concussive devices that are built into the start zone of avalanche tracks can be deployed during or after snow events and at night.

Mitigation activities to limit risks to mountain goats are primarily based on conducting surveys for goats prior to initiating avalanche control and pausing control activities until goats have cleared avalanche paths. Mitigation activities depend on the choice of avalanche control. Three methods of avalanche control are currently used for the Mine; each has an associated survey protocol to ensure the site is clear of people or wildlife prior to detonation. These include:

1. Hand-based blasting is conducted predominantly at the base of the avalanche path using case charges which consist of a high explosive suspended on a bamboo pole tripod and remotely detonated. These are placed on or slightly above the BJAR. Ski-touring and throwing hand charges may also be employed up slope from the road: prior to conducting hand-based blasting the crew conducts visual confirmation the site is clear of people or wildlife along avalanche path and start zone. If goats are present, blasting will be delayed until they have left the area. Air horns or other suitable sounding devices may be used to herd goats away to a safe distance before blasting begins. If this is required, then a General Wildlife Permit application will be submitted to BC MFLNRORD.
2. Helicopter-based blasting is conducted at the top of avalanche paths and most often to be used in spring to clean up sites. It includes dropping of explosive charges out of the helicopter to initiate and avalanche from above: prior to conducting helicopter-based blasting, there is a detailed sweep of the slope to determine where best to place targets ensuring a thorough survey of the path and surrounding area for hazards and goats. If the area and area immediately adjacent (within 100 m) to the avalanche path is clear, blasting will proceed. If not, goats will be herded away to a safe distance before blasting begins if possible. If terrain and snow conditions preclude herding goats away from the area, blasting will be delayed until goats clear the area.

Figure 5.3-1
Location of RACS Units

PRETIVM

Proj # 0194150-0008 | GIS # BJP-23-223c

Over the past four winters during which helicopter-based blasting has been conducted for avalanche control at the Mine and along the BJAR, no mountain goats have been observed within or in proximity to the avalanche control sites at the time control was being conducted. Pre-blast visual inspections have been conducted as part of standard procedure to ensure that the areas are clear of both personnel and wildlife, including mountain goats.

3. In-place RACS concussive devices, of which Pretium uses two different systems, were installed at three of the most problematic sites along the BJAR. These devices may be operated remotely during any weather and are used to initiate avalanches at the top of the path. During clear weather, a ground-based survey of the avalanche track is conducted from a safe location using a spotting scope or similar device. Site-specific details are described in Section 6.1.3. If goats are observed and safety is not compromised, then blasting will occur once mountain goats move out of the avalanche area. Air horns or other suitable sounding devices may be used to herd goats away to a safe distance before blasting begins. If blasting is planned during obscured conditions with low lying cloud or fog, heavy snowfall or wind events, pre-blast surveys may not be feasible.

As some approaches to mountain goat deterrence may be novel, all avalanche management activities considered will be documented and summarized in an annual report. The results of avalanche mitigation activities will be used in an adaptive management approach to inform future actions. Documentation will include:

- Survey methods and results;
- Any mitigation required – deferring the avalanche control or use of air horns; and
- Results of avalanche control.

Details of the avalanche control methodology were included in the Licence of Occupation applications submitted by Pretium to BC MFLNRORD, which were subsequently approved.

5.3.2 Risk to Mountain Goats from Avalanche Control Measures

This section evaluates the risk to mountain goats resulting from avalanche control measures at a site level using field data on the locations of proposed avalanche control measures, goat habitat, and goat occupancy collected during 2015. There are several avalanche zones identified along the BJAR and near the mine site. Avalanche control measures in all areas follow the mitigation and adaptive management approach described in Section 5.3.1.

Within each of the zones there are areas that are managed for avalanches; these include areas along the BJAR at 2 km, 30 km, 44 km, 56 km, 58 km, 59 km, and the area around the Brucejack Camp. While the event frequency and size of avalanches vary, of the areas requiring most consistent avalanche control, the areas at the Brucejack Camp, 56 km, and 2 km are not identified as key goat winter habitat, and goats were not observed at any of these locations during inventory (Rescan 2011). Slopes above the BJAR at 30 km are near a UWR, however goats were not identified in this area during inventory. The UWR is at the top of the avalanche zone, and control measures are only expected to be associated with the lower slope above the road. Consequently, goats are not expected to occupy this area when avalanche control is required.

Risk to goats from avalanche control at the Brucejack Mine Site, 56 km, 30 km, and 2 km is considered very low. Directed monitoring for goats is not proposed for these sites beyond the scanning protocol that currently occurs for avalanche control using helicopter-based or hand-based blasting described in section 5.3.1. If, for exceptional circumstances, goats are observed within avalanche tracks planned for blasting, avalanche control will be halted until the goats have cleared the area. If required, noise will be used to herd goats out of the danger area as described in Section 5.3.1. The response of goats to noise will be documented (Section 5.3.1).

Avalanche control at 44 km and 58 km is the most likely to provide a risk to mountain goat. The 59 km site has also been assessed for risk to mountain goat. All three methods of control may potentially be used at these sites, however, the ground-based RACS represent the avalanche control of greatest consequence to goats in size of area, potential goat occupancy, and frequency of use. The RACS are remotely fired with a charge of compressed oxygen and propane, Gasex®, or 4 kg explosive charge dropped from Wyssen Towers to initiate an avalanche. The RACS used to manage avalanche hazards will be installed at three key locations along the Brucejack Access Road. The Gazex® is permanently fixed at the top of the avalanche paths at 44 km, while Wyssen Towers are installed at the top of avalanche paths at 58 km and 59 km (Figure 5.3-1). A monitoring plan has been identified for use with RACS avalanche control in these areas and it can be extended to include all methods of avalanche control at these problematic sites.

To evaluate the potential risk to mountain goats at these three sites from the installation of the RACS and other avalanche control systems, a field survey was carried out in May 2015 (June 17, 2015, Wildlife Trip Report). The survey was conducted, in part, to evaluate the likelihood that goats would occupy the areas slated for avalanche control. The risk to goats was evaluated based on the results of this survey combined with the information available from habitat suitability mapping, spatial distribution of habitat, and the anticipated goat use. Locations at 44 km and 58 km were identified as potentially supporting use, while goat winter use at km 59 is not anticipated. The risk to mountain goats from avalanche control at these three sites was qualitatively evaluated based on professional judgement of habitat suitability and potential occupancy during the winter. The habitat value, and therefore likelihood of habitat uses and risk to goats, was referenced to a local benchmark; the UWR unit on the north side of Bowser Lake which supports substantial goat numbers (12 observed in the winter 2011 survey at this location). This UWR is located at Anderson Mountain approximately 5 km away from the 10 km marker on the Brucejack Access Road, along Wildfire Creek, and is not expected to be disturbed by Mine-related activities.

The Gazex® RACS unit at 44 km is at the edge of a large UWR complex that has potential to support several goats. This avalanche control site is at the lower, south, and eastern edge of the complex, and while goats may occupy the site during winter, there is habitat of higher quality and greater connectivity north of the site. Within the UWR, goats were observed in May 2015 (waypoint 043, Figure 5.3-1) up slope on the mountain within the UWR. Goats were observed in a favourable area of green vegetation near the large UWR polygon during the May 2015 reconnaissance. The 2011 winter ungulate surveys (Rescan 2011), did not detect goats in this area, but identified a total of 14 goats to the north and west of the 44 km UWR polygon unit. The RACS unit will affect a large area downslope from the UWR polygon unit (Plate 5.3-1). Considering the isolation of this unit at the periphery of a larger more suitable complex, the probability of it being occupied by goats during avalanche control is low and with monitoring, risk to goats is predicted as Low as well. The 44 km avalanche control area was checked for presence of mountain goats and other wildlife as part of standard pre-blast procedures during

blasting that occurred over the past four winters; no mountain goats were observed within the blast areas.

Plate 5.3-1. Location of RACS unit exploders at 44 km site.

The first Wyssen RACS site is comprised of one tower located at 58 km at the southern end of the Knipple Glacier portion of the BJAR. One mountain goat was observed at this location during the May 2015 reconnaissance, and goats with kids had been recorded near this site in 2011 prior to July 1 as recorded in the July 14, 2011, Vegetation and Wildlife Critical Review trip report. No goats were observed during winter 2011 survey near this location (Rescan 2011) and the survey unit associated with the site only had one goat observed during the winter 2011 surveys. The habitat was assessed as high-quality winter habitat as it supports vegetation including conifer cover and shrubs adjacent to escape terrain. The area potentially affected by the RACS is at the lower elevation of the suitable habitat, where escape terrain is becoming fragmented, and connectivity to more contiguous habitat is reduced in winter (Figure 5.3-2). Considering the location at the edge of habitat and no documented winter use, it has a low probability of being occupied by goats during avalanche control, and risk to goats is predicted as Low with monitoring. As with the 44 km area, km 58 was also checked for mountain goat presence prior to blasting over the past four winters and no goats were observed within the avalanche zone.

The second Wyssen RACS site is comprised of 11 towers located between 59 and 60 km and was assessed as low-quality winter habitat for goats. This site is in area recently exposed as the Knipple Glacier receded and has virtually no vegetation cover that would provide winter forage to goats. Its value as escape terrain is also marginal as it is small and surrounded by more gently rolling topography (Figure 5.3-2), and only a small, low elevation area will be impacted by the RACS. No goats were observed near this site during the 2011 winter inventory (Rescan 2011) and only one goat was observed in survey unit (SU) 10. The probability of this site being used during winter by goats is very low and risk to goats is predicted as Very Low. No goats have been observed at this location during previous avalanche blasting activities.

Figure 5.3-2. Location of Wyssen Towers between Km 58 and 60 of the Brucejack Access Road

6 ENVIRONMENTAL MONITORING

6.1 PERFORMANCE MONITORING

6.1.1 Clearing Monitoring

Any additional pre-clearing surveys will be completed by consultants or environmental staff (preferably Registered Professional Biologists) with appropriate experience and/or training with mountain goats in BC. As described in Section 5.1 however, almost all planned clearing has been completed to date and any further clearing required in sensitive areas will occur between September 5 and November 1, outside of the sensitive periods for mountain goats.

Monitoring frequency may be triggered during vegetation clearing but not during normal operations thereafter. Monitoring will occur for clearing activities that will occur in winter (November 1 until April 30) within 500 m the mountain goat UWR. The objective for surveys will be to conduct them as close to clearing as possible, with a maximum of 72 hours before clearing. The pre-clearing survey will survey for goats out to 2-3 km from the proposed clearing site, covering the area of mountainside defined by drainages unlikely to be crossed by goats. If a particular block of mountain side does not have goats, then the clearing teams are free to clear within 72 hours. If goats are found within 1.5 km of the clearing site, then: 1) a further pre-clearing survey will be conducted, 2) the site will be surveyed as the crews are being put out, or 3) the clearing schedule will be altered to clear that site later, following another pre-clearing survey. If the pre-clearing is conducted within 24 hours of clearing, and the area within 500 m of the clearing site is clear of goats, then clearing can continue as planned.

Ground surveys may be used to supplement helicopter-based surveys if topography requires, and weather and work safety allows it. Flight scheduling for monitoring will be conducted by a Registered Professional Biologist with appropriate experience and/or training with mountain goats in BC.

6.1.2 Aircraft Monitoring

Pilots are asked to report incidental observations of goats as part of the incidental wildlife reporting program as discussed in the Wildlife Monitoring Plan (Pretium 2023). Employees who feel that pilots have flown too close to goats are encouraged to report this to Brucejack Logistics or environmental staff.

6.1.3 Avalanche Monitoring

Monitoring during avalanche control activities is conducted to minimize potential mountain goat mortality during avalanche control measures.

Avalanche control monitoring information collected include:

- Location;
- Date;
- Time;

- Personnel;
- Methods and results of pre-control surveys;
- Mitigation actions including;
  - all wildlife herding actions and other mitigative measures,
  - wildlife response,
  - subsequent rationale for decision regarding blasting (including decision not to trigger an avalanche);
- Any blasting activity undertaken; and
- Notes on results.

As listed above, the monitoring measures include visual surveys before avalanche control is initiated to the extent feasible, mitigation efforts and their effects, decision making, and avalanche control results. The avalanche control results include post-control surveys to evaluate if any goat mortality has occurred. The RACS units located at 44 km, 58 km and 59 km along the BJAR have been predicted as having a Low (44 km and 58 km) or Very Low (59 km) risk to goats. Surveys conducted in May 2015 identified varied risks at each location considering connectivity of habitat, habitat quality and spatial distribution of habitat and goats.

The site at 44 km includes a large area of slope that tails out over the BJAR and into the Bowser River. This control is initiated by six Gazex® RACS exploders. The initiation zone is in the low elevation portion of a UWR polygon that has been identified as potentially used by goats. When feasible – i.e., when avalanche control is to be conducted during clear weather conditions – spotting for mountain goats (and moose at the tail out) will be conducted from the ground with a spotting scope (or similar device) prior to detonation of exploders. Spotting will be conducted from 44.4 km. The observer will be in communication by radio and give the all clear when there are no goats within 100 m of the “Slasher” avalanche path

The site at 58 km includes a relatively short run and small area at the bottom of the slope that can be initiated by a Wyssen Tower RACS exploder. The site is expected to have a Low risk to goats and can be observed on the ground by a monitor with a spotting scope prior to detonation. Spotting for 58 km will be done from the causeway across the Bowser River, as there is no safe location with good visibility closer to the 58 km site. The observer will be in communication by radio and give the all clear when no goats are observed in openings within 500 m from the blast location.

The sites between 59 and 60 km include a large area of slope that tails out over the BJAR at several locations and is managed by 11 Wyssen Tower RACS exploders. The area is predicted to have a Very Low risk to goats as such no monitoring is proposed.

Monitoring for mortalities will occur as a check by environmental staff in the spring, with mortality evidenced by signs of goats or as signs of scavenging by predators or birds. Monitoring will be implemented if evidence of goat use is identified through the course of development.

6.2 WORK PLANNING AND SCHEDULE

The mitigation and management measures for mountain goats that will be implemented to eliminate or minimize adverse effects will occur throughout the various Mine phases.

7 REPORTING AND RECORDING

7.1 REPORTING

7.1.1 Compliance Reporting

Compliance reporting will be subject to EA Certificate conditions, and *Mines Act* permit conditions.

Compliance reporting for a wildlife permit used to herd mountain goats away from avalanche paths, if needed, will be reported separately to BC MFLNRORD as detailed in the permit.

The results of monitoring and mitigation are reported to the Wildlife Advisory Committee (WAC).

7.1.2 External/Internal Reporting

All personnel are encouraged to report wildlife observations made anywhere within the Mine. Information collected during monitoring activities, including incidental observations, is summarized in the daily wildlife monitoring log.

7.1.3 Incident Reporting

Incident reporting includes observations of mountain goats during pre-clearing surveys, mountain goat encounters with aircraft/helicopters not following appropriate mitigation measures, and wildlife interactions with avalanche mitigation actions. In addition, any mortality and/or encounters during vegetation clearing surveys, or other mortality events, are reported.

7.2 RECORD KEEPING/TRACKING

7.2.1 Monitoring Results

Information collected during monitoring activities includes the effort that the monitor has put into surveying (start and end times), as well as documenting information on goat observations including time of observation, physical condition, age, sex (if possible) and number of goats. Notes on behaviour and response to the activity will also be recorded, as will observations of other sensitive wildlife incidentally observed.

7.2.2 Continuous Improvement, Follow up, and Adaptive Management

Mitigation measures will continuously be improved by recording incidents involving mountain goats and following up on these incidences and implementing adaptive management when or if current mitigation measures are ineffective.

VERSION CONTROL

Revision #	Date Released	Author	Approval	Amendment
0	Nov 16, 2015	Patrick Mueller, Lorax	-	Replacement for the Nitrite Management Plan
1 - Draft	July 29, 2016	Patrick Mueller, Lorax	Lyle Morgenthaler, Pretium	Document reorganization
1 - Final	November 10, 2016	Patrick Mueller, Lorax	Lyle Morgenthaler, Pretium	Update N loading rate and mine water plot
2 – Draft	March 27, 2019	Patrick Mueller, Lorax Colleen Atherton, Pretium	Lyle Morgenthaler, Pretium	Align NMP with MOE Guidance; Update monitoring procedures, benchmarks and monitoring metrics based on operational data
3 - Final	July 27, 2020	Patrick Mueller, Lorax Colleen Atherton, Pretium	Lyle Morgenthaler, Pretium	Update production blasting methods; add surface blasting source control procedures; update Sections 4, 5, 6, 7, 8 and 9 to reflect current practice
4 – Final	March 17, 2022	Nathan Glas, Pretium Patrick Mueller, Lorax	Robin McCall, Pretium	Annual Review with updates to monitoring results, waste rock deposition practices, ore blasting practices and training conducted. New sections for audit results and conclusions were added.
5 – Final	March 1, 2023	Nathan Glas, Pretium Patrick Mueller, Lorax	Torence Sandhals, Pretium	Annual review with updates to monitoring results, powder factor monitoring practices and associated blasting procedures, along with mine water loading rate procedure update.

AUTHORSHIP

This Nitrogen Management Plan (NMP), revision 5, was updated from revision 4 by Nathan Glas, M.A.Sc., P.Geo. Pretium Resources Incorporated (Pretium) with input and review by Patrick Mueller, B.Sc., P.Chem of Lorax Environmental Services Limited (Lorax), the acting qualified professional (QP) for this plan. Revision 5 provides updated details surrounding:

- Changes to drilling equipment and data management practices that have resulted to changes in how the development and production powder factors (PF) are calculated;
- Changes to procedure for monitoring nitrogen (N) Loading from waste rock deposition by incorporating a 2 year averaging period to obtain more representative and normalized results;
- A summary of NMP monitoring results to the end of 2022;

GLOSSARY AND ABBREVIATIONS

Terminology used in this document is defined where it is first used. The following list will assist readers who may choose to review only portions of the document.

AN	Ammonium Nitrate
ANFO	Ammonium Nitrate Fuel Oil
ENV	BC Ministry of Environment and Climate Change Strategy (formerly MOE)
BJAR	Brucejack Access Road
CWP	Contact Water Pond
EBR	Electro-biochemical Reactor
EMA	*Environmental Management Act*
EMLI	Ministry of Energy, Mines and Low Carbon Innovation
EMS	Environmental Management System
IX	Ion Exchange
MA	*Mines Act*
MBBR	Moving Bed Biofilm Reactor
MDMER	Metal and Diamond Mining Effluent Regulations
MEMPR	Ministry of Energy, Mines and Petroleum Resources (formerly MEM)
MERP	Mine Emergency Response Plan
MOE	Ministry of Environment
N	Nitrogen
NMP	Nitrogen Management Plan
NPAG	Not Potentially Acid Generating
OMS	Operations Maintenance and Surveillance
PAG	Potentially Acid Generating
PF	Powder Factor (kg explosive / tonne rock)
QA/QC	Quality Assurance/ Quality Control
STP	Sewage Treatment Plant
WRTSF	Waste Rock and Tailings Storage Facility
WTP	Water Treatment Plant
WZ	West Zone

1 PURPOSE

The purpose of this Nitrogen Management Plan (NMP) is to provide guidance for Pretium Resources Inc. (Pretium), a member of the Newcrest Group of companies, regarding minimization and management of the release of soluble nitrogen compounds (ammonia, nitrite and nitrate) associated with explosives at the Brucejack Mine (Brucejack or the Mine). This plan aims to: 1) describe potential sources and pathways of nitrogen; 2) document the potential risk to the environment; 3) describe the monitoring plan for ensuring that the environmental risks are minimized; 4) outline the management triggers for implementing mitigation should it be necessary; and, 5) outline potential mitigation and timelines for implementation.

2 SCOPE

This NMP is intended to provide guidance to Pretium on nitrogen management and applies to all individuals working for or on behalf of Pretium, including employees and contractors who have a role and/or accountability for the development, implementation and maintenance of this NMP.

This NMP has been developed in accordance with applicable legislation, regulations and guidelines. Environmental protection is a requirement of both the BC *Mines Act* (1996) and the Health, Safety and Reclamation Code for Mines in British Columbia (EMLI, 2021). The movement, storage, use and disposal of explosives at mines in BC are regulated pursuant to Part 8 of the Code. Discharge is authorized under section 120 (3) of the BC *Environmental Management Act* (2003) and is administered by the BC Ministry of Environment and Climate Change Strategy (ENV) under Effluent Permit 107835 (PE-107835). Discharge limits for ammonia, nitrite and nitrate are regulated at the outlet of the Waste Rock and Tailings Storage Facility (WRTSF) and are summarized in Table 2-1.

Table 2-1: Effluent Permit PE-107835 discharge limits for Nitrogen (N) compounds at BJ 3.10.

Parameter	Discharge Limit (mg-N/L)
Ammonia	4.0
Nitrite	0.24
Nitrate	11.5

The following Federal and Provincial legislation, regulations and guidance documents are relevant for nitrogen management, the handling of explosives and the discharge of effluent from mining operations:

- Federal *Explosives Act* (R.S.C., 1985, c. E-17);
- Federal *Explosives Regulations* (SOR/2013-211);
- Federal *Fisheries Act* (R.S.C., 1985, c. F-14, as amended) Sections 34(2), 36(3), 36(5) and 38(9);
- Federal *Metal and Diamond Mining Effluent Regulations* (MDMER; SOR/2002-222);

- Health, Safety and Reclamation Code for Mines in British Columbia (EMLI, 2021);
- BC *Mines Act* Permit M-243 Section D.1 (EMLI, 2022);
- BC *Environmental Management Act* Effluent Permit 107835 Conditions 1.1 and 3.2 (ENV, 2022);
- BC *Municipal Wastewater Regulation* (Reg. 87/2012) domestic wastewater;
- BC *Spill Reporting Regulation (*BC Reg. 187/2017); and,
- BC Guidance on Preparing Nitrogen Management Plans for Mines using Ammonium Nitrate Fuel Oil Products for Blasting (ENV, 2018)

Field sampling and laboratory testing are undertaken according to procedures outlined in the following:

- *British Columbia Field Sampling Manual for Continuous Monitoring and the Collection of Air, Air-Emission, Water, Wastewater, Soil, Sediment and Biological Samples* (ENV, 2020a; and,
- *British Columbia Laboratory Manual* (ENV, 2020b).

3 INTRODUCTION

Pretium owns and operates the Brucejack Mine located in northwest British Columbia approximately 65 km NNW of Stewart by air. Brucejack is an underground gold mine with related surface infrastructure including a mill, mine water treatment plant (WTP), subaqueous waste rock and thickened tailings slurry deposition sites, accommodations, transmission line and off-site infrastructure (Figure 3-1). Commercial production was achieved July 2017 and the planned operating life of the mine is approximately 14 years at an annual ore production of 1.387 Mt (3,800 tpd) as described in Lorax (2020).

The BC Environmental Assessment Office issued BC Environmental Assessment Certificate #M15-01 on March 26, 2015. During the next five months Pretium applied for, and received *Mines Act* Permit M-243 and *Environmental Management Act* Permit for discharge of effluent (PE-107835) based on an annual ore production of 0.99 Mt. The *Mines Act* and *Environmental Management Act* permits were amended in December 2018 following an application for increased ore production of 1.387 Mt (3,800 tpd) and have most recently been amended in November 2022 to reflect expansion of the Permitted Mine Area (PMA) and June 2022 to update sewage treatment plant authorizations and amend nomenclature from Brucejack Gold Mine to Brucejack Mine, respectively.

Over the life of the mine, underground excavation will total approximately 5.3 Mt of waste rock and 18.5 Mt of ore, mined at a 3800 tpd production rate in accordance with the *Mines Act* permit (EMLI, 2021). Nitrogen residues are exported from blasted rock on the blasted rock surfaces and in contact water (Pommen, 1983; Wiber *et al*., 1991; Forsyth *et al.*, 1995). The release of nitrogen (N) compounds from blasting is directly related to the quantity of explosives used for blasting a tonne of rock. Blasting residuals associated with rock excavation can mobilize from the following:

- To mine water from blasted rock surfaces through contact with groundwater and water used for dust suppression;
- To mill process water from ore surfaces;
- To mine water from paste backfill bleed water and waste rock backfill seepage;
- To the WRTSF through waste rock and tailings deposition;
- To the WRTSF though discharge of treated WTP and sewage treatment plant (STP) effluent;
- To the WRTSF through NPAG quarry runoff and rock used for road surfacing.

Elevated concentrations of ammonia, nitrite and nitrate in Brucejack Creek may be harmful to aquatic resources. Although fish are not present in Brucejack Creek, insects (e.g., mayflies) are present. The discharge limits for ammonia, nitrite and nitrate specified in PE-107835 are protective of these organisms.

The following sections summarize sources of nitrogen compounds, material and water management, the NMP monitoring programs and results, and N source control procedures implemented at Brucejack. This plan will be routinely updated as relevant information becomes available and management practices are refined.

4 NITROGEN SOURCES AND CONTROL PROCEDURES

4.1 Explosives Products and Hazard Classes

Explosives residues are a widely recognized source of ammonia, nitrite and nitrate in contact water and blasted rock surfaces (Pommen, 1983; Ferguson and Leask, 1988; Wiber, 1991; Forsyth, 1995; Cameron *et al*., 2007; Morin, 2009; Bailey *et al*., 2013; Mueller, 2015; Sidenko, 2018). Nitrogen constitutes approximately 25% of the ammonia nitrate (AN) based explosive product used at Brucejack, apportioned almost equally between ammonia and nitrate as N, while nitrite is an oxidation product of the explosion reaction. Treated domestic wastewater is also a source of ammonia and nitrate, however this represents a small proportion of the nitrogen load discharged to the WRTSF therefore N source control measures are focussed on explosives use. Water soluble nitrogen compounds are transported to the aquatic environment downstream of the mine through discharge from the WRTSF at station BJ 3.10.

Nitrogen residues are exported from blasted rock on the blasted rock surfaces and in the contact water. The release of N compounds from blasting is directly related to the quantity of explosives used for blasting a tonne of rock (also known as a powder factor, or PF) and the blasting method used. Blasting conditions (and PF) vary on a daily basis and are therefore evaluated over longer periods (*i.e.,* monthly).

The primary explosive used for underground blasting at Brucejack is the following AN-emulsion product:

- TITAN® 7000 sensitized bulk emulsion manufactured by Dyno Nobel; DOT hazard shipping description: explosive, blasting, type E 1.5D II, UN0332.

Packaged AN-emulsion explosives are also used for small areas and include:

- Dyno® AP detonator sensitive water-resistant emulsion explosives packaged in plastic. DOT hazard shipping description: explosive, blasting, type E, 1.1D, UN 0241 II;

- DynoSplit® nitroglycerin dynamite packaged in rigid paper cartridges. DOT hazard shipping description: explosive, blasting, type A, 1.1D, UN 0081 II.

The primary explosives used for surface blasting at Brucejack include:

- Dyno® Blastex booster sensitive, water-resistant, packaged emulsion explosive. DOT hazard shipping description: explosive, blasting, type E, 1.5D, UN 0332 II.

Detonators and Boosters used for underground and surface blasting include:

- Dyno TROJAN® SPARTAN® detonator sensitive cast boosters, high density, high energy molecular explosives. DOT hazard shipping description: boosters, 1.1D, UN 0042.

4.2 Explosives Transport, Storage and Blasting Procedures

The majority of explosives used at Brucejack are employed in the excavation of waste rock and ore in the underground mine. A limited volume of explosives are used at the mine site for quarrying NPAG rock for road surfacing and building foundations. Additional blasting is conducted for NPAG quarry excavation along the Brucejack access road (BJAR) to generate material for road construction and maintenance.

Procedures to minimize transfer of nitrogen to the environment are required at all locations where explosives are used. Considerations for nitrogen source control are included in Appendix A and Appendix B for surface blasting and underground blasting, respectively. Explosives use within the M-243 permit area is restricted to water insensitive products such as bulk and packaged AN-emulsion. Due to typically dry conditions and limited excavation volumes, ANFO products are permitted at NPAG quarry sites along the BJAR, however, at this stage they have not been utilized.

Health and safety and explosives handling practices are the responsibility of the blasting contractor and are described in the SOPs prepared and controlled by the blasting contractor. Pretium requires that the blasting contractor health and safety practices comply with the regulatory requirements outlined in Section 2.

Explosives are stored in restricted areas that are secure and locked and access is limited to authorized personnel only. Bulk emulsion and packaged emulsion products are stored in magazines and are used first-in, first-out to prevent degradation from storage. Spoiled emulsion explosives are deposited into the designated waste tote and returned to the supplier.

Blasting is used to excavate underground drifts and stopes, and for surface excavation at NPAG quarries. Blast hole patterns are designed by Mine Engineers and field fit as needed to excavate a specific volume of rock. Adjustments are made based on visual observation of rock fragmentation. Explosives are loaded with boosters and detonators and detonator tie in is conducted just prior to a blast.

Development blasting methods are used to advance drifts and access tunnels for underground mining operations. The blasts are conducted with a short hole pattern of 60 to 80 horizontal holes to a depth of 2.8 to 4.2 m with an open square blast face typically 5.5 by 5.5 m in dimension. Small diameter boreholes (51 mm) are drilled for loading explosives and the explosives use rate (powder factor or PF) for development blasting is high relative to other blasting methods used at Brucejack.

Ore is excavated at Brucejack via longitudinal or transverse open stoping production blasting methods. Stopes are excavated by advancing drifts at 30 m intervals. Longholes (101.6 mm diameter) are then drilled from the top or bottom drift in a parallel or radiating fan pattern. Stopes are typically 30 m high and 15 m wide, and the length of the stope varies depending on the mine plan. The initial blast in a stope, termed the slot, requires a higher PF than the remaining blasts; therefore, smaller stopes will generate higher PFs. Overall, the production PF is significantly lower than for development blasting. Blast holes were previously drilled by Sandvik Solo top-hammer drills that produced 3.5 inch holes. However, in 2021 ITH drills were commissioned and these produce a 4 inch hole that increases the amount of explosives used for each blast compared to the smaller 3.5 inch blast holes. The Mine completed the transition to ITH drills during 2022. Although the blast hole spacing has been updated for the ITH drills, the revised blast patterns yield a higher emulsion to blasted rock ratio over the

previous 3.5 inch holes and associated blast patterns, and this is reflected in the 2021 and 2022 Production PF monitoring results.

Surface blasting at the km 72 NPAG Quarry is conducted using packaged AN-emulsion. Surface blasting at quarries along the BJAR (*e.g.,* at km 59 NPAG Quarry) may also use ANFO if dry blasting conditions are present within the quarry. The km 72 and km 59 NPAG Quarries are a source of rock for fill material and road surfacing, with the km 72 NPAG Quarry providing material for the Brucejack Site and the km 59 NPAG Quarry providing material for the Brucejack Access Road. Blast holes are drilled down from the surface to a depth and over an area specified in the blast pattern design prepared by the mine engineer. The powder factors for surface blasting are generally lower than for underground blasting. Similar to nitrogen audits of underground blasting procedures, surface blasting nitrogen audits were initiated in 2022, with one completed at the km 72 NPAG Quarry.

The following protocols for underground blasting practices are prepared and used by the mining contractor, Procon Mining and Tunnelling Ltd. (2008):

- Brucejack-UND-EXP-001 Central and Remote Blasting
- Brucejack-UND-EXP-002 Underground Longhole Explosives Loading
- Brucejack-UND-EXP-003 Re-Entering the Workplace After Blasting
- Brucejack-UND-EXP-004 Loading a Development Round
- Brucejack-UND-EXP-005 Disposing Waste Explosives
- Brucejack-UND-EXP-007 Blasting Oversize – Remote Stope Muck
- Brucejack-UND-EXP-008 Blasting Oversize Muck During Shift
- Brucejack-UND-EXP-009 Transporting & Receiving Explosives
- Brucejack-UND-EXP-010 Transferring Emulsion Underground
- Brucejack-UND-EXP-011 Receiving and Transporting Emulsion ISO Container with A64 Getman Hauler

4.3 Source Control

Source control is generally recognized as an effective strategy for N mitigation and this is implemented at Brucejack Mine through the use of best practices for explosive handling and blasting, as well as domestic wastewater management. Explosives are the primary source of N in Brucejack Mine discharges. Nitrogen source control is achieved through good explosives handling and spill clean-up procedures. Considerations for N source control are summarized in Table 4-1 and are reviewed during regular inspections to evaluate implementation. Additional source control considerations for surface quarrying and underground mining are provided in Appendix A and Appendix B, respectively.

Table 4-1: Nitrogen Control Measures for Explosives Use

Activity	Nitrogen Control Considerations
Explosive Selection	• Select water-resistant explosives appropriate for site conditions (e.g., AN-emulsion)

Blast pattern design	• Design patterns to achieve desired fragmentation with minimum explosives use
Blast hole loading	• Dewater blast holes • Use packaged explosive for flowing holes • Minimize the loaded pattern “sleep” time (the elapsed time between explosives loading and detonation) • Clean up all spilled explosives
Water management	• Divert water away from blast holes and/or contact surfaces
Disposal	• Detonate with regular blasting • Collect and ship off-site for disposal

4.4 Nitrogen Cycling

Nitrogen from explosives residues may be present as ammonia (defined as NH_3, NH_4^+), nitrite (NO_2^-) and nitrate (NO_3^-). The relative distribution of nitrogen between ammonia, nitrite and nitrate in the WRTSF can shift due to naturally occurring nitrogen cycling processes. Nitrification reactions in the natural environment are mediated by nitrifying organisms that are ubiquitous in groundwater, lakes and streams (Ward et al., 2011; Ward, 2013) and in cold water environments (Small et al., 2013; Clevinger, 2013). Empirical observations from Brucejack monitoring data indicate nitrification processes that convert ammonia to nitrate are active in the WRTSF. Nitrate is the dominant N containing species at the WRTSF outlet and typically accounts for > 98% of the total nitrogen exported from the WRTSF. Nitrification processes are expected to control the nitrogen species distribution in the WRTSF discharge throughout mining and closure. The processes that control nitrogen cycling in the WRTSF are discussed in detail in Appendix C.

5 MATERIAL MANAGEMENT

5.1 Blasting

Development and Production blasting, using the methods described in Section 4.2, generate blasted rock at the blast location (*i.e.*, muck piles). Water is sprayed onto the muck pile at the blast site for dust suppression following each blast. Monitoring data indicate that some of N loads on the blasted rock are transferred to mine water at the blast location. However, the majority of the N containing residues remain on the blasted ore and waste surfaces. The annual tonnages blasted, and explosives used for Development and Production blasting are provided in Table 5-1.

Table 5-1: Annual Development and Production Blasting Tonnage and Explosives Use

Year	Development Blasting (t)	Development Explosives Use (kg)	Production Blasting (t)	Production Explosives Use (kg)
2015	225,226	319,433	-	-
2016	768,238	1,374,220	-	-
2017	675,264	1,141,313	440,839	346,209
2018	651,531	1,135,531	825,464	687,485
2019	779,124	1,356,416	1,115,052	983,046
2020	941,543	1,541,517	1,092,670	932,722
2021	893,734	1,695,208	1,026,936	1,018,560
2022	789,731	1,578,750	1,001,966	1,129,722

5.2 Waste Excavation and Deposition to WRTSF or Backfill

Waste rock at Brucejack is managed via subaqueous deposition either as backfill in portions of the underground mine that will ultimately be flooded upon closure, or deposited in the WRTSF. Waste rock destined for WRTSF deposition is transported to the surface via scoop and underground haul truck where it is temporarily deposited near the portal before being transferred to the waste rock deposition platform by a surface haul truck. Waste rock is either directly deposited on the waste dump pad for deposition to the WRTSF, or temporarily stored in a stockpile until such time that it can be deposited. Waste can be stockpiled for several reasons, such as during winter months when the lake is frozen, during turnover when deposition is halted, and during maintenance or other activities occurring on the waste dump pad that preclude waste deposition. Waste rock deposited in the WRTSF builds up and eventually forms the waste rock deposition platform where some waste rock extends to or above the normal WRTSF water level. This subaerially exposed PAG waste rock is periodically replaced with either NPAG material or freshly excavated PAG waste rock, or left with a 1 m water cover, such that surface-deposited PAG waste rock is ultimately subaqueously deposited with a minimum 1 m water cover within the allowable two-year exposure period. On July 11, 2022 waste deposition was halted due to increased settlement rates on the dump pad. On July 16, 2022 the waste pad experienced a failure, at which point deposition was halted from mid-July to mid-August to allow for geotechnical stability evaluations to be undertaken before continued waste deposition could occur.

Prior to May 2021, waste transferred to the WRTSF was segregated into two waste streams: 8 inch minus and 8 inch plus. The 8 inch minus material was deposited into the WRTSF using a stacker. Material larger than 8 inches was placed into the WRTSF by bailing with a backhoe. The volume of waste rock placed in the WRTSF was estimated using backhoe bucket loads fed to the stacker and truck counts of oversize material removed for bailing. In May 2021, the use of a remote-controlled dozer was initiated, which allowed all material to be pushed into the WRTSF using one methodology. The volume of waste rock placed in the WRTSF is now tracked using truck loads. The stacker has been dismantled and decommissioned, but there is still the ability to bail material in the future as required. The temporary waste stockpile at the end of 2022 was approximately 232,460 m^3.

For 2022, deposition did not occur from January through April or in December, deposition volumes were higher and consistent from May through mid-July, with a deposition gap from mid-July to mid-August, followed by lower but consistent deposition from mid-August to late October and low and intermittent deposition through later November. The annual waste rock excavation and deposition quantities for 2020-2022, and planned through 2032 are shown in Table 5-2 (Lorax, 2020).

Table 5-2: Annual Waste Excavation and Deposition Schedule from 2020 through 2032.

Year	Waste Excavation [1] (kt)	Waste Delivered to WRTSF [1] (kt)	Waste Deposition to Backfill [1] (kt)
2020	761	720	41
2021	1,011	804	207
2022	850	626	224
2023	*486*	*46*	*439*
2024	*392*	*199*	*193*
2025	*389*	*85*	*305*
2026	*315*	*121*	*195*
2027	*264*	*149*	*115*
2028	*44*	*13*	*31*

2029	*36*	*1*	*35*
2030	*35*	*6*	*29*
2031	*7*	*2*	*5*
2032	*4*	*4*	*0*

[1] 2020-2022 are actual values, whereas 2023 through 2032 are projected values provided by Pretium for the 2020 water quality model update (Lorax, 2020).

5.3 Ore Processing

Ore is excavated at Brucejack using production blasting methods described in Section 4.2 via longitudinal or transverse open stoping. A portion of ore, typically less than 15%, is generated during development blasting for excavation of drifts. Following blasting, ore is transferred to the underground crusher via remote scoop and rock truck. Crushed ore is transferred to the surge bin within the mill via conveyor and from there is directed to the SAG mill for grinding. Process water is also directed to the SAG mill and monitoring data suggest that most or all the soluble N species on ore surfaces are transferred to process water in the SAG mill. The annual ore production quantities for 2020-2022, and planned through 2032 are shown in Table 5-3 (Lorax, 2020).

Table 5-3: Annual Ore Production Schedule

Year	Ore Production [1] (kt)
2020	1,309
2021	1,383
2022	1,254
2023	*1,386*
2024	*1,388*
2025	*1,388*
2026	*1,388*
2027	*1,180*
2028	*1,180*
2029	*902*
2030	*801*
2031	*561*
2032	*189*

[1] 2020-2022 are actual values, whereas 2023 through 2032 are projected values provided by Pretium for the 2020 water quality model update (Lorax, 2020).

5.4 Tailings Deposition to WRTSF or Paste Backfill

Tailings are managed via subaqueous deposition at depth in the WRTSF or placed as cemented paste backfill in the underground mine. Nitrogen species are water soluble and the primary method of transmission of N from tailings to the WRTSF is via the liquid fraction (*i.e.,* supernatant) of the tailings slurry. Tailings supernatant is composed of mill process water that has been influenced by N loading from WTP effluent and ore. During the winter, the primary discharge of water to the WRTSF typically occurs in the form of tailings supernatant discharged with the tailings slurry.

Monitoring of backfilled stopes indicates that limited water is released during and after backfilling and therefore cemented paste backfill is not expected to contribute a significant N load to mine water. The annual tailings deposition quantities for 2020-2022, and planned through 2032 are summarized in Table 5-4 (Lorax, 2020).

Table 5-4: Annual Schedule for Tailings Deposition to the WRTSF and Paste Backfill

Year	Tailings Deposition to WRTSF [1] (dry kt)	Tailings Deposition to Paste Backfill [1] (dry kt)
2020	797	432
2021	900	406
2022	804	379
2023	*982*	*328*
2024	*882*	*440*
2025	*929*	*389*
2026	*877*	*442*
2027	*722*	*400*
2028	*669*	*450*
2029	*508*	*349*
2030	*461*	*300*
2031	*297*	*231*
2032	*87*	*89*

[1] 2020-2022 are actual values, whereas 2023 through 2032 are projected values provided by Pretium for the 2020 water quality model update (Lorax, 2020).

6 WATER MANAGEMENT

6.1 Underground Water Management

Mine dewatering is conducted to allow excavation of new workings, with water directed to the WTP for treatment prior to discharge. The historic West Zone (WZ) workings will remain flooded below approximately 1275 m asl until development of the WZ commences. A cross section of the underground workings at the end of 2022 are shown colour-coded in Figure 6-1 and the conceptual water management schematic is given in Figure 6-2.

Water drains from the upper levels of the workings and is pumped from the lower levels to the 1300 level sump and from there to the WTP for treatment (Figure 6-2). Sumps and pipelines are used to manage and convey water, and driving surfaces are covered with construction aggregate (3/4” or 3” screened quarry crush).

Figure 6-2: Conceptual diagram of the underground water management system on December 31, 2022.

6.2 Surface Water Management

Site surface runoff from the contact water management area is directed to the CWP and water levels within the CWP are managed as described in the Water Management Operations Maintenance and Surveillance (OMS) Manual (Pretium, 2020). Inputs to the CWP include surface runoff collected via the contact water management system and surplus WTP effluent recirculated to the CWP for water storage. Water withdrawn from the CWP is directed to the WTP for treatment.

Inputs to the WRTSF come in the form of treated effluent from the STP and WTP, along with water as a component of tailings. Additionally, water can enter the WRTSF through waste rock deposited to the WRTSF, where water can be retained either as snow or water within waste rock pore space. Non-contact water can also naturally flow into the WRTSF. A schematic of the site water balance is provided in Figure 6-3.

Figure 6-3: Site water balance schematic, with water quality model N source terms highlighted.

6.3 Water Treatment Plant (WTP) and Sewage Treatment Plant (STP)

The Water Treatment Plant (WTP) is located within the mill building and is designed to treat TSS and dissolved metals, however ammonia, nitrite and nitrate are not removed by the treatment process. The WTP receives water from mine dewatering, the CWP and from the mill (Figure 6-3). The treated WTP effluent is recycled to the fresh/fire water tank for mill and mine water supply, and to the CWP for storage and future recycling. Surplus treated effluent is discharged to the WRTSF by pipeline to the deep water of the WRTSF. Treated effluent from the WTP represents the cumulative effects of N transmission to mine water, process water and surface runoff, and treated WTP effluent was discharged to the WRTSF at an average of 914 m^3/day in 2022, with the majority of discharges occurring between late May and late November.

Domestic wastewater from the camp and other surface facilities is directed by pipelines to the STP, which consists of two parallel treatment streams. Treated domestic wastewater effluent is discharged by pipeline to the deep waters of the WRTSF. A schematic of water conveyance to and from the STP is shown in Figure 6-3. The STP discharged an average of 88 m^3/day in 2022.

7 WATER QUALITY PREDICTIONS

The Brucejack water quality model (Lorax, 2020) predicts water quality at various locations in the Brucejack water management system, at the WRTSF outlet (B 3.10) and in Brucejack Creek (BJ 2.62). The projected site water balance, life of mine schedules for mining, milling and waste deposition, and loading rates for each source of ammonia, nitrite and nitrate are combined in the model to generate water quality predictions at the modelled locations. Source terms are prepared to model base case and upper case scenarios; the base case represents the expected water quality whereas the upper case represents a scenario with poor nitrogen source control. The water quality model source terms for ammonia, nitrite and nitrate are empirically derived from monitoring records for explosives consumption, ore and waste production, water quality and flows for the 2015 through 2019 operational period.

Explosives-related nitrogen species are currently introduced to the WRTSF from waste rock deposition, tailings slurry discharge, WTP effluent, STP effluent, NPAG Quarry rock contact water and mine site surface runoff (Figure 6-3). Although the dominant inputs to the WRTSF are from the waste rock, tailings slurry and WTP effluent, source terms are developed and modelled for all known inputs of nitrogen to the WRTSF including background and STP loadings. However, N loads from background and treated domestic wastewater input are minimal and are not further reviewed in the NMP. The input of N from explosives will cease at Closure when blasting stops and mine flooding occurs. It is expected that the soluble N species will be released to the flooded mine pool from walls, floors and backfill to mine water during mine flooding.

The water quality model predictions for ammonia, nitrite and nitrate concentrations in site waters are based on excavation, deposition, N loading rate and water balance assumptions. Comparison of measured values to model assumptions is important to maintain confidence in the water quality predictions for N species. The water quality model source terms for mine water, waste rock and ore are presented and compared to monitoring results in Section 8.4 through Section 8.6. The predicted and measured water quality of discharge from the WRTSF are discussed in Section 8.7.

8 NITROGEN MONITORING PROGRAMS AND RESULTS

8.1 Overview

The NMP uses data from various ongoing water quality and flow monitoring programs as well as mining and milling records for nitrogen source control monitoring. Audits of blasting practices are conducted at underground and surface blasting locations to regularly review the N source control procedures that are used for explosives handling and blasting. Ammonia, nitrite, nitrate and total nitrogen are measured in all water quality samples collected for NMP monitoring. The monitoring and auditing programs are summarized as follows:

- **Blasting Quantities and Explosives Use Records:** Underground blasting is conducted daily for mine development and ore production. Records are kept for explosives use and tonnage blasted. These records are used for explosives use monitoring and are combined with derived N loads to calculate N loading rates for blasted rock to mine water, waste rock and ore.

- **Km 72 NPAG quarry:** Nitrogen contributions to the WRTSF from NPAG quarry blasting are monitored in surface water samples that are periodically collected from pooled water or runoff in the vicinity of the quarry. The N concentrations in runoff from the NPAG quarry are low: water from two samples collected in August and September of 2022 contained <0.030 and 0.095 mg-N/L total nitrogen, respectively, similar to the concentrations observed in 2020 and 2021 and indicating quarry blasting is a minor influence on the N species concentrations in the WRTSF.

- **Surface water quality monitoring**: Water quality monitoring includes water quality and flow monitoring at several locations of interest for N management. These stations include surface contact water runoff into the CWP, Mine Water, CWP Water, Process Water, WTP Effluent and the WRTSF outlet (BJ 3.10). Monitoring of the fresh/fire water tank was added in 2020 to monitor the water supply to the mine. Concentrations at the WRTSF outlet (BJ 3.10) are compared to management triggers and discharge limits. Samples are collected in accordance with the procedures described in BJ-ENV-SOP-035 - Water Treatment Plant Sampling and BJ-ENV-SOP-021 – Water Quality Sampling for Compliance Site BJ 3.10. The N species concentrations and flows measured for mine dewatering, and WRTSF discharge, are used to derive N loading rates for blasted rock to mine water, and to determine a WTP effluent point load for calculation of the waste rock N loading rate to the WRTSF.

- **Water column monitoring:** Water column sampling is periodically conducted at BJ 35, located near the deepest area of the WRTSF. Water column samples are collected at approximately 10 to 15 m intervals and field parameters are measured *in situ* using submersible sensors according to Brucejack sampling procedures described in BJ-ENV-SOP-059 - Open Water Lake Monitoring and Sampling. Water column profiles are also collected using a CTD that measures temperature, conductivity, pH, dissolved oxygen and turbidity. Sampling intervals are typically aligned with turnover events and conducted approximately mid- month January, April, July and September, with additional sampling completed as required. The water column N species concentrations and lake volume-elevation curve are used to calculate the N inventory in the WRTSF for the determination of the waste rock N loading rate to the WRTSF.

- **Underground mine walls**: Nitrogen residues are expected to accumulate on mine walls during mining and be released to mine water during mine closure when the mine is flooded. The build up of nitrogen residues is monitored annually at several underground stations as part of the mine wall station monitoring program, as described in BJ-ENV-SOP-038 – Mine Wall Station Water Quality Sampling. The monitoring data are used for water quality modelling of nitrogen release from mine walls to mine water during Closure.

- **Paste backfill bleed water:** Paste backfill is expected to release a limited quantity of water (bleed water) at the time of placement in the underground mine. Paste bleed water monitoring is conducted at two stopes per year and includes monitoring of nitrogen compounds, as

described in BJ-ENV-SOP-011 – Underground Chromium Sample Collection. These data are collected and used to derive a source term for modelling the transfer of nitrogen from paste bleed water to mine water.

- **Ore processing and tailings discharge:** The contribution of N from ore processing is monitored at two locations: the SAG mill, where water quality can be monitored at both the inlet and the outlet, and tailings supernatant. SAG mill monitoring data are used to derive an ore N loading rate that represents the transmission of N from ore to process water. Quantities of N transferred from tailings to the WRTSF are determined from the tailings supernatant water quality and discharge volumes and are used to determine a point load for the derivation of the waste rock N loading rate to the WRTSF. The procedures for collecting tailings supernatant and samples from the SAG mill are described in Brucejack sampling procedures BJ-ENV-SOP-007 – Tailings Grab Sample Collection and BJ-ENV-SOP-41 – SAG Mill Sampling, respectively.

- **STP discharge monitoring:** Treated domestic effluent is monitored at the STP discharge for flow and N species. These data are used to derive N source terms for STP discharge and to calculate a point load for the determination of the waste rock N loading rate to the WRTSF.

- **N source control audits:** Routine internal audits are conducted for N source control. The frequency of underground NMP audits, typically monthly, is adjusted as needed in response to previous audit findings and monitoring metrics. The surface blasting audit program was implemented in 2022 and will be conducted annually for each year that surface blasting is conducted. The audit checklists provided in Appendix E are used for evaluation of surface and underground blasting and explosives handling practices. Audit reports are maintained, and corrective actions are identified for implementation and follow-up.

The data and records collected through the monitoring programs outlined in Section 8.1 are analyzed and used to derive metrics for evaluating N source control. These metrics are compared to trigger values to determine when further investigation or action are warranted. A monthly time step is used for most metrics. Waste rock deposition metrics are prepared approximately quarterly. The full set of monitoring results for N species along with other parameters are presented on an annual basis in the Brucejack Mine Annual Report. The formulas used to calculate the NMP metrics are described in Appendix D.

8.2 Explosives Use

Loading rates for N from explosives are dependent on blasting efficiency, which varies depending on the method of excavation, and the type of rock that is blasted. Blasting efficiency can be measured using the powder factor (PF) which is the quantity of explosives used to blast a tonne of rock. Over the long term (> 12 months) the PF is generally stable; however, the PF can vary over monthly periods due to normal variations in blasting conditions. Significant and sustained increases in PF may indicate a N source control issue that will lead to an increase in the N loading rates from blasted rock; therefore, management triggers have been established for PF monitoring to trigger investigation of N source control procedures as described in Section 9.4.

Mining is conducted for access tunnels (development drifts) and for ore excavation (production stopes). Different blasting methods are employed for development drifts and ore stopes as described in Section 4.2, however similar approaches are used for N source control based on the considerations described in Appendix B. Management triggers were previously established at the 90th percentile of monthly PF values from the June 2017 through December 2018 period (0.88 and 1.75 kg/t, for production and development blasting, respectively). Improvements to blasting and recordkeeping methods that have been progressively implemented since mid-2020 have resulted in calculated PF values that are higher in 2021 and 2022, compared to the June 2017 through December 2020 period, and are generally greater than the PF trigger values. However, a corresponding increasing trend for the N loading rates to mine water, and on ore and waste is not observed indicating the change in PF values did not alter the amount of N exported to the WRTSF. Therefore, from January 2023 onwards, management triggers are not applied to the PF monitoring results. The establishment of new trigger values will be evaluated once sufficient monitoring data are collected. A breakdown of the PF monitoring results is provided below.

Monthly records indicate relatively consistent Production PF values from June 2017 through December 2020 that were occasionally above the trigger value of 0.88 kg/t. as shown in Figure 8-1. Production PF was elevated above the trigger value from May to November 2019 due to drilling modifications which required re-optimization of the blast pattern design to improve blasting efficiency and return the production PF to below the trigger level. Almost all of the Production PF values for 2021 and 2022 were above the currently suspended trigger value (0.88 kg/t).

The increase in Production PF is attributed to a modification of the method used to calculate stope volumes, and to changes in the blast hole dimensions. Previously, the stope volume calculation assumed the blast extended one meter beyond the end of the blast holes. Starting in July 2020, stope volume calculations did not extend beyond the blast holes, resulting in smaller blasted volume estimates for stopes. This change results in a higher calculated PF compared to the methods in use when the current (0.88 kg/t) management trigger was established. The calculated PF for production blasting has increased in 2021 and 2022 relative to 2017-2020. This increase is due to the use of larger diameter blast holes, as described in Section 4.2, which lead to an increase in the explosives usage rate.

Updates to the Development explosives use recordkeeping practices were implemented in 2021 and again in 2023. Prior to 2021, Development PF was derived using metered and calculated values recorded on daily blasting reports. In 2021, the recording methodology was modified to use the annual explosives quantities invoiced by Dyno and the annual tonnage blasted, expressed as a monthly average value. In 2023, the derivation procedure was further revised and the monthly Development PF values for 2021 and 2022 were recalculated. The updated procedure uses a correction factor derived from the ratio of explosives delivered (corrected for production usage) and the reported development usage on an annual basis. The explosives amounts recorded on daily blasting reports are multiplied by the correction factor (*i.e.*, 1.11 and 1.10, for 2021 and 2022, respectively*)* and the resulting values are used to derive the monthly Development PF values. This method proportionately increases the PF value compared to using the unscaled emulsion use records. Therefore, in order to maintain inter-comparability of the Development PF values, the 2021 and 2022 average scaling factor (*i.e.,* 1.105) was retroactively applied to the PF values that were previously reported for the 2017 through 2020 period. The revised Development PF values for the June 2017 through December 2022 period are plotted in Figure 8-1 and show an increased number of trigger exceedances. Overall, an increasing

Development PF trend is observed with values generally higher in 2022 than in prior years. Additional monitoring data will be collected and assessed prior to establishing an updated trigger value.

As an outcome of training sessions completed in 2021, tracking of the frequency and quantity of non-detonated explosives in the muck was initiated and was evaluated as a possible metric that may indicate N source control issues. The tracking program is still ongoing and is qualitatively utilized by underground personnel to identify issues related to poor source control practices, however, it was found to have no discernable correlation to observed N species concentrations at BJ 3.10 or variations in PF. With this in mind, tracking of this metric was suspended in relation to the NMP.

Figure 8-1: Powder factor (PF) for underground development and production blasting compared to management trigger values.

8.3 Blasted Rock Excavation and Deposition to the WRTSF

The Lorax (2020) water quality predictions are based on the planned excavation, milling and deposition schedules to the WRTSF. Table 5-1, Table 5-2, Table 5-3, and Table 5-4 show ore and waste excavation, waste deposition to the WRTSF, and tailings deposition to the WRTSF. The tables present 2020-2022 actual values, alongside 2023 to 2032 modelled values, allowing for comparison of actual quantities to the model assumptions moving into the future.

8.4 Mine Water

Nitrogen residues are transferred from blasted rock to mine contact water through the infiltration of groundwater into the mine, through spraying down muck piles for dust suppression and flush water from the mill after pasting a stope. Nitrogen loads originating from WTP treated effluent and the WRTSF reclaim water are also transferred to mine water via the mine water supply. Data used to calculate the N loading rate for blasted rock to mine water include mine water N species concentrations, mine dewatering flows (measured at WTP influent station) and blasted tonnes of ore and waste. The calculated mine water N load is corrected to subtract the loads contributed from the mine water supply. The corrected N loads still include N originating from paste backfill operations. However, the contributions from backfilled paste are difficult to accurately quantify and due to very low contact flows are considered minor, therefore the corrected mine water N load is conservatively assumed to originate entirely from blasted rock. The measured N loading rate is compared to the water quality model base case and upper case source terms. Calculation of the N loading rate to mine water is described in Appendix D.

The N loading rate from blasted rock to mine water fluctuated from 0.012 to 0.046 kg-N/t on a monthly basis from June 2017 through December 2022 and typically remained between the base case and upper case modelled rates (0.022 to 0.033 kg-N/t, Figure 8-2). The observed monthly loading rates are corrected for contributions from the water supply (Fresh/Fire Water) from September 2020 onwards. The N load from the water supply is subtracted by accounting for the T-N concentration and the volume of water that is transported underground on a monthly basis. The loading rates used for the water quality model were derived using monitoring data from January 2015 through July 2017 (Lorax, 2018 and 2020), before significant recycling of N through the mine water supply commenced.

In June and August of 2021, the monthly loading rates exceeded 0.04 kg-N/t. This increase is inferred to be related to the intersection of the Windy Fault underground. This fault was intersected by various stopes and along the West Zone Ramp. The Windy Fault produced significant amounts of water during the period of June to August, both along the West Zone Ramp and at several faces, which could have resulted in increased transfer of N from blast residues to mine water during these months. Similar increases were observed between 2015 and 2017 due to equipment issues that resulted in loss of non-detonated explosives to mine water when fault structures were intersected at faces. Active water production made the loading of faces difficult and increased associated emulsion spillage and waste. Loading rates for 2022 largely stayed within the bounds of the base case and upper case modelled rates, with three exceptions. Investigations have not yet identified specific causation, but review is ongoing.

Figure 8-2: Monthly nitrogen (N) loading rate to mine water from blasted rock (ore and waste) compared to water quality model assumptions and the cumulative loading rate for the June 2017 through December 2022 period.

8.5 Ore and Tailings

Ore is moved from stopes to the underground crusher for processing and delivered to the mill hopper by conveyor. Minimal water contact with ore occurs until it is directed to the SAG Mill for grinding. The N loads from ore are exported from the mill in WTP effluent, tailings and ore concentrate. The N loading rate from ore to process water is determined using the SAG influent and effluent water quality, the SAG water feed rate and the SAG ore feed rate as described in Appendix D and is compared to the water quality model base case and upper case source terms.

The water quality model base case and upper case ore N loading rates (0.028 and 0.054 kg-N/t) are derived from the 75th and 90th percentiles of a high frequency (*i.e.,* weekly) monitoring dataset collected June through September 2017 (Lorax, 2018 and 2020). The ore N loading rate was measured weekly from June through October 2017, and monthly thereafter through December 2022, and is plotted in Figure 8-3. Weekly values are compiled and plotted as monthly average values for the June through October 2017 period. The N loading rates are generally below the base case model assumption of 0.028 kg-N/t, with a median loading rate of 0.022 kg-N/t for the values plotted in Figure 8-3 (June 2017 through December 2022).

Figure 8-3: Nitrogen (N) loading rate from ore to process water compared to the period median value and the water quality model loading rate assumptions for ore.

Mill tailings are discharged to the WRTSF or backfilled to the mine as cemented paste backfill. The N loading rate from tailings to the WRTSF is monitored using monthly tailings supernatant samples and flow data as described in Appendix D. The monthly N loading rate in tailings during the period from June 2017 through December 2022 ranged from 0.020 to 0.100 kg-N/dry t as shown in Figure 8-4. The cumulative N loading rate of 0.053 kg N/dry t is derived from the cumulative N load and tailings tonnage discharged over the June 2017 to December 2022 period. The water quality model predicts N species concentrations in tailings supernatant based on N inputs from mine water and ore; therefore, a tailings N loading rate is not currently used for modelling. Monitoring of the tailings N load rate is conducted to aid with N source control investigations and for comparison to the loading rates for mine water and waste.

Figure 8-4: Nitrogen (N) loading rate in tailings supernatant compared to the cumulative loading rate for the June 2017 through December 2022 period.

8.6 Waste Rock

Nitrogen residues on waste rock are transferred to the WRTSF primarily during sub-aqueous deposition. Waste rock is removed from the underground for disposal in the WRTSF where it is assumed to instantaneously release 100% of the N load to the WRTSF water at the time of deposition. As mine development proceeds, some waste rock will be retained in the underground mine as backfill, where the N load will be transmitted to mine water. Estimates of N transmitted to the WRTSF via waste rock deposition are made by subtracting N contributions from measurable point sources (*e.g.,* WTP effluent, tailings and STP effluent) from the change in N inventory derived from water column samples and N exported via BJ 3.10 as described in Appendix D. With this version of the NMP the method used to derive the N load loads on waste rock is modified to extend the averaging period from approximately three months to 24 months as described below.

The base case and upper case modelled N loading rates for waste rock are derived from January 2015 through July 2017 monitoring data (Lorax, 2018 and 2020) using approximately quarterly averaging periods. The previous version of this NMP noted that this approach was generating a wide range of values (*i.e.,* 0.008 to 0.295 kg-N/t) for the late 2018 through 2021 dataset. The averaging calculations were modified to use a two year averaging period to smooth out the loading rate fluctuations. The loading rate is assigned to the last year in the two year period. Utilizing a longer time period yields N loading rates for 2017 through 2022 that are similar to, but also generally lower than the base case and upper case loading rates developed from the January 2015 through July 2017 data, as shown in (Figure 8-5). The derivation method for this loading metric will be periodically re-evaluated moving forward. Overall, the N loading rates for waste show a declining trend from 2017-2018.

Figure 8-5: Nitrogen (N) loading rate for the transfer of N from waste rock to the WRTSF compared to water quality model loading rates.

8.7 WRTSF

The WRTSF discharges at BJ 3.10 and receives all Brucejack contact waters, as well as waste rock and tailings deposited in the WRTSF. Tailings, WTP and STP effluent are discharged by pipeline at depth into the WRTSF, whereas waste rock is deposited from the waste rock deposition platform. Vertical mixing of WRTSF waters is limited during the open water and ice covered seasons due to thermal stratification of the water column; however, mixing of the water column occurs during turnover events. Waste rock deposition is expected to promote limited vertical mixing by drawing surface water to depth during deposition.

Spring turnover events follow the melting of ice on the WRTSF. Vertical mixing typically occurs through most of the water column as cold surface water warms and sinks when maximum density is attained at ~4°C. As surface water becomes more buoyant with increasing temperature, stratification establishes a surface and deep water layer that do not mix until temperatures cool in the fall. When autumn surface water temperatures return to ~4°C, almost full vertical mixing reoccurs until surface waters cool to become sufficiently buoyant once again. Wind driven mixing contributes to this seasonal mixing process, termed turnover, and the effect of wind driven mixing tends to be stronger in fall. Deposition of a thickened tailings slurry at the bottom of the WRTSF has resulted in an additional stratified bottom layer, which resists mixing due to the density effect of the suspended solid load contributed by tailings deposition.

From 2015 through 2020, turnover was observed in spring and fall. However, since 2021, turnover has only been observed in the fall. This has led to sub-oxic conditions (i.e. dissolved oxygen below

1 mg/L) in the deeper waters during summer, from 10 to 30 m below the surface to the bottom of the water column. If the absence of spring turnover becomes a permanent feature of the WRTSF then sub-oxic conditions at depth are expected to develop annually, from late spring through to autumn turnover in October or November. The development of sub-oxic zones may influence nitrogen cycling processes within the water column, and monitoring data will continue to be evaluated for changes in the nitrogen cycling trends within the water column.

Varying inputs to the water column, *e.g.*, tailings discharge at depth, and the effects of stratification can result in variable concentrations of N species throughout the water column with higher concentrations at depth compared to surface. Variability of up to two orders of magnitude have been observed for NH_3 concentrations within the WRTSF. Over time, tailings and waste deposition will reduce the WRTSF water column depth and volume. A WRTSF volume-elevation curve has been developed and is updated based on bathymetric surveys that are conducted approximately annually. The volume-elevation curve estimates the volume of water associated with the water quality at a specific depth in order to calculate the N inventory in the WRTSF as per Appendix D.

Overall, the N inventory in the WRTSF has increased during mining; with a general leveling off beginning in 2019. Some seasonal decreases that are associated with freshet flows or autumn rains observed from 2018 onwards. A summary of the N inventory measurement in the WRTSF from January 2014 through October 2022 is presented in Figure 8-6.

Figure 8-6: Summary of total N inventory in the WRTSF.

Weekly samples are collected from compliance point BJ 3.10 in accordance with Condition 1.1 and Appendix A of Effluent Permit PE-107835. The permit specified discharge limits for ammonia, nitrite and nitrate are presented in Table 2-1 and Figure 8-7. Discharge limits were initially established when PE-107835 was issued on August 31, 2015 and were revised in the amended permits issued on March 31, 2017 and December 14, 2018 (Table 8-1). Management triggers were implemented in March 2019 with version 2 of the NMP and are discussed in Section 9.4. In revision 3 of the NMP the nitrate

management trigger was revised from 8 to 10 mg-N/L, which is approximately equal to the base case predicted maximum value (Figure 8-7, bottom plot).

Table 8-1: Effluent Permit PE-107835 discharge limits for N compounds at BJ 3.10 over time.

Parameter	August 31, 2015 Discharge Limit (mg-N/L)	March 31, 2017 Discharge Limit (mg-N/L)	December 14, 2018 Discharge Limit (mg-N/L)
Ammonia	1.0	1.0	4.0
Nitrite	0.075	0.240	0.240
Nitrate	3.0	11.5	11.5

Ammonia and nitrite concentrations at BJ 3.10 are below discharge limits, base case water quality predictions and NMP management triggers as shown in Figure 8-7. Nitrate concentrations have been tracking the base case predicted values and were generally stable in 2022 except when seasonal low concentrations are typically observed in June following the onset of spring freshet. One nitrate value (10.2 mg/L) on May 16, 2022 was observed to be above the NMP management trigger. The associated duplicate that was collected on May 16, 2022 was below the trigger value (9.9 mg/L) and follow up samples from the following week were both below the NMP management trigger and showed a decreasing trend. It was determined that this was an isolated occurrence. Ammonia and nitrite are well below base case predictions and fluctuate seasonally, and the accumulation of both parameters is typically observed from approximately November to February, followed by declining concentrations from approximately March through June. The seasonal increase in the concentrations of these parameters is associated with fall turnover of the water column that is speculated to result in a temporary interruption of the natural microbial nitrification processes in the WRTSF. Ammonia and nitrite predictions model a no nitrification endpoint for the WRTSF. However, observed concentrations of these parameters are well below the base case predictions thereby providing indirect evidence that naturally occurring processes in the WRTSF are converting ammonia and nitrite to nitrate.

Figure 8-7: Results of BJ 3.10 water quality monitoring compared discharge limits, water quality model predictions and management trigger values.

8.8 Nitrogen Source Control Audits

Nitrogen source control audits were generally conducted underground at a quarterly frequency in 2016 and a monthly frequency since February 2017 with a total of 77 audits completed to the end of December 2022 (Table 8-2). Typical issues corresponded to excessive emulsion spillage at the face, deteriorated explosive/emulsion labelling, poor loading or handling, poor housekeeping, or other spills noted in the area. Issues were typically addressed at the time of the audit, or mitigation requirements were developed and followed up with crews on subsequent audits to ensure deficiencies were rectified. Generally, there has been a decrease in major and minor deficiencies from 2016 to present. Surface blasting audits were implemented in 2022, with one audit completed, and no issues observed.

Overall, the audits completed in 2022 noted good adherence to N source control procedures for explosives handling and blasting at underground excavations. Several areas for improvement were occasionally identified, including; emulsion spillage observed at the blast face, inadequate housekeeping, and excessive loading of blast pattern. These deficiencies were addressed by modifying procedures, providing training to blasting personnel and conducting follow-up audits to

ensure the effective implementation of corrective actions. Generally, discussions were had with the blast crew during explosives loading such that emulsion spillage could be cleaned up at the time, housekeeping could be addressed, and inadequate loading practices could be rectified in real time.

Table 8-2: A summary of nitrogen (N) source control audits completed each year since 2016 indicating the number of source control non-conformances that were identified and addressed.

Year	Audits Completed	Issues Observed	Issues Corrected
2016	4	7	7
2017	14	11	11
2018	11	3	3
2019	12	5	5
2020	12	10	10
2021	12	4	4
2022	12	7	7

9 NITROGEN MANAGEMENT

9.1 Overview

Management of N at Brucejack includes procedures for explosives use, best practices for N source control, water quality monitoring and regular audits of blasting practices. The monitoring data are evaluated and if the results are above a trigger level further investigation is undertaken to inform management decisions for the implementation of mitigation needed to meet discharge limits at BJ 3.10. Collectively, the following activities are conducted to support N management at Brucejack:

- Training of mine and environmental staff;
- Implementing best practices for explosives use and domestic wastewater management;
- Evaluation of options for treatment of N species;
- Monitoring, recordkeeping, auditing and program reviews;
- Using management triggers to initiate management response to ensure discharge limits are met at BJ 3.10; and
- Implementing corrective actions to address non-conformances and follow-up to evaluate effectiveness.

The monitoring programs developed for N species are described in Section 8. The other key elements of N management at Brucejack are described in the following sections.

9.2 Training

Personnel and contractors involved with explosives use at Brucejack Mine are trained by Pretium to understand best blasting practices, the environmental impacts of explosive use and methods for minimizing those impacts. Performance evaluation and follow-up training is provided to relevant personnel to support implementation of best practices.

In 2021 the Environmental Department provided NMP training to the Geology and Technical Services Departments that reviewed N source control procedures for underground blasting. In 2023, there are plans to present similar presentations to all underground workers regarding the Nitrogen Management Plan and Source Control Procedures to ensure all individuals are aware of the importance of reducing excess emulsion and explosive use and to clearly identify how they can contribute to reducing this problem on site.

The Pretium Environmental Department, in partnership with Lorax presented Nitrogen Prediction and Management at Brucejack Mine at the BC MEND Metal Leaching/Acid Rock Drainage 28th Annual Workshop in December of 2021 (Mueller & Fredrickson, 2021). Participation in industry workshops and conferences provides opportunity to learn from industry peers and for sharing N management experience gained at Brucejack Mine.

9.3 Treatment

Treatment for nitrite was periodically implemented during the Exploration and Construction phases of Brucejack Mine (late-2014 through May 2017). A nitrite discharge limit for WTP effluent was specified in Approval 106251 which was in effect from September 3, 2014 through August 30, 2015, and in EP- 107835 from August 31, 2015 though March 30, 2017. The WTP effluent was discharged to Brucejack Creek late October 2014 through December 23, 2015. From December 24, 2015 and onwards, the WTP effluent has been discharged to the deep waters of the WRTSF.

Monitoring data collected in 2016 indicated that nitrite was being removed within the WRTSF by natural processes indicating treatment of the WTP effluent was not necessary to meet discharge limits at the WRTSF outlet (BJ 3.10). Brucejack Mine applied for permit amendments in 2016 that included the request to remove the nitrite discharge limit for WTP effluent on the basis that the nitrite concentrations were being controlled by processes in the WRTSF. The March 31, 2017 amendment to PE-107835 does not specify a nitrite limit for WTP effluent. However, discharge limits for ammonia, nitrite and nitrate continue to be applied at BJ 3.10, the final discharge location.

The WTP commissioned in late 2014, during Exploration, was configured to treat for nitrite using hydrogen peroxide. The treatment of nitrite using this method was ineffective and residual concentrations of the oxidant caused *Ceriodaphnia* toxicity test failures in the WTP effluent. Therefore, this treatment method was abandoned and a nitrite source control program was implemented to control nitrite concentrations in mine water.

A new nitrite treatment system was procured by Brucejack Mine and treatment using sodium hypochlorite was commissioned mid-2015 for the Construction WTP, and was effective at removing nitrite from the influent waters. The system was activated from November 11th through December 23rd, 2015, and February 6th through May 3rd, 2016. Ammonia was incidentally treated as well and, due to

the high ammonia concentration relative to nitrite, significantly more hypochlorite reagent was consumed than the amount required to treat for nitrite only.

Therefore, in 2016, the Construction WTP was upgraded to use ozone which targeted the treatment of nitrite only. The switch to ozone eliminated the unnecessary use of reagents to treat nitrite compared to the hypochlorite process, noting that ammonia was not treated by the ozone process. Monitoring data indicate the ozone system was activated from September 16th through December 1st, 2016, and effectively treated nitrite during this period.

The Operations WTP in use since mid-2017 does not treat nitrite and all N species pass through the WTP untreated. The base-case water quality predictions (Lorax, 2020) indicate that all N species are expected to remain below WRTSF discharge limits assuming that good N source control procedures are continuously implemented. Therefore, N source control is selected as the primary mitigation for N compounds during Operations and treatment is considered a secondary option.

In consideration of upper-case predictions that indicate nitrate may exceed discharge limits, Pretium previously undertook a review of nitrate treatment technologies (Lorax, 2017). Three technologies were identified for further evaluation and possible implementation, should future monitoring data indicate the nitrate discharge limit is likely to be exceeded:

- Moving bed biofilm reactor (MBBR): MBBRs utilize an attached growth process, in which microorganisms form as biofilms on inert packing media and are used to treat nitrate. An MBBR bench test for nitrate treatment was undertaken in early 2015. The results indicate that Brucejack mine water can be treated for nitrate using this technology.

- Electro-biochemical reactor (EBR): EBRs supplement the biological nitrate reduction process by supplying electrons to the reactor using an applied voltage, in addition to nutrients required to sustain the biofilm.

- Ion exchange (IX): for IX, ions in solution adsorb onto the surface of a solid material (resin) achieving high nitrate removal efficiencies.

Further evaluation to support the selection of treatment technologies will be conducted if ongoing NMP monitoring data, or changes to the mine schedules, indicate treatment will be required to meet discharge limits for ammonia, nitrite or nitrate at BJ 3.10, the WRTSF outlet.

9.4 Nitrogen Management Triggers

Threshold trigger values are used to initiate investigation and corrective action for N source control or mitigation. Nitrogen management trigger levels have been defined for powder factors (PF) (development and production blasting) and N species concentrations at BJ 3.10 (Table 9-1). Note that the PF trigger values are not currently applied due to changes in Production blasting methods and Development recordkeeping, as described in Section 8.2. The trigger levels were derived from operational data and water quality model predictions. If monitoring metrics are below the trigger values, then N source control measures are considered to be effective and N species concentrations at BJ 3.10 are expected to remain well below regulated discharge levels. Temporary upset conditions may occasionally result in a short term trigger exceedance. If a trigger exceedance is observed, then the

Mine Manager and Environment Manager are notified, and a management investigation and response is initiated.

Table 9-1: Trigger values for nitrogen management

Monitoring Metric	Trigger Value
Powder factor, development blasting (kg/t)	1.75 [1]
Powder factor, production blasting (kg/t)	0.88 [1]
BJ 3.10 ammonia (mg-N/L)	0.50
BJ 3.10 nitrite (mg-N/L)	0.10
BJ 3.10 nitrate (mg-N/L)	10

[1] The PF trigger values are not currently applied due to changes in Production blasting methods and Development recordkeeping, as described in Section 8.2

A significant increase in the powder factor may alter N loading rates from blasted rock to contact water. The variation in monthly values is typically small, therefore, the 90th percentile values of the monthly development and production PF values from the June 2017 to December 2018 period were selected as trigger values to flag possible excessive explosives use. As discussed in Section 8.2, the Production and Development PF values have been generally above the trigger levels in 2021 and 2022. The PF trigger levels will be re-derived once a sufficiently large data set for statistical evaluation is obtained.

Trigger values at BJ 3.10 have been set at concentrations considered to identify significant changes in nitrification processes and N loadings that may influence future water quality at BJ 3.10. The concentrations of N species at BJ 3.10 are influenced by N loads input to the WRTSF and the N species conversions that occur in the WRTSF. Monitoring data indicate that nitrate is the dominant N species at BJ 3.10, generally accounting for more than 98% of the N measured in the discharge. Therefore, based on trends in monitoring data, trigger values for ammonia and nitrite have been conservatively set at 0.5 and 0.1 mg-N/L, respectively, to indicate possible changes to the natural nitrification processes that are active within the WRTSF.

The observed concentrations for nitrate are at base case levels (Figure 8-7). Prior to 2020, the nitrate trigger value was set to 8 mg-N/L although predictions indicated concentrations would reach 10 mg-N/L. The trigger value was exceeded in 2020, and a review of monitoring data indicated nitrate was closely tracking base case predictions for the WRTSF outlet, therefore the trigger value was reset to 10 mg-N/L, the maximum predicted base case concentration (Lorax, 2020), and well below the 11.5 mg-N/L discharge limit for nitrate.

In the event of a trigger level exceedance, Pretium will follow the steps outlined in the trigger response flow chart shown in Figure 9-1. The initial response to the management trigger exceedance is an investigation to identify root cause and corrective action. The investigation will be conducted as described in Section 9.5. Following the investigation, appropriate mitigation measures will be identified and implemented, as necessary. The efficacy of the mitigation will be evaluated based on follow up monitoring results.

Figure 9-1: Schematic of the NMP trigger response process that is activated when management trigger exceedances are observed.

9.5 Investigation and Corrective Action

In the event that monitoring results indicate a management trigger value is exceeded, an investigation will be carried out to identify the root cause of the exceedance. The investigation may include, but will not necessarily be limited to, the following:

1. Verification of results through collection of additional samples to be analyzed for total nitrogen, ammonia, nitrite and nitrate, where applicable.

2. Determining the potential cause(s) based on indications in the monitoring data and in consultation with mine staff to determine if routine operations or extraordinary circumstances resulted in the elevated N.

3. A visual inspection of the underground mine to determine possible sources of N.

4. Expansion of the monitoring program to identify the source of elevated N, if warranted.

5. An assessment of the severity of the occurrence and likelihood of recurrence.

6. Recommendations for immediate source control and ongoing mitigation.

A review of the investigation will be prepared by Pretium Environment staff. The review may include, but will not necessarily be limited to, the following information:

- A description of the triggering incident;
- A description of the investigation that was undertaken;
- An assessment of the root cause;
- Recommended action; and,
- A summary of the source control measures that were implemented.

Corrective actions will be implemented in accordance with this plan and reviewed for effectiveness. If further improvements are necessary, these will be tracked with the original incident file. The Environmental Manager is responsible for ensuring that the corrective actions are tracked until an incident is considered to have been addressed. Relevant records are summarized for annual reporting.

9.6 Emergency Procedures and Response

A Mine Emergency Response Plan (MERP) has been developed by Pretium in accordance with the Health Safety and Reclamation Code for Mines in British Columbia (EMLI 2021). This MERP outlines response procedures in the event of a variety of incidences including spills of hazardous substances and unplanned explosions. Emergencies will be immediately communicated to the Pretium emergency response coordinator and response plans and activities will be coordinated by Pretium.

9.7 Roles and Responsibilities

This NMP applies to all individuals working for, or on behalf of, Pretium including employees and contractors who have a role and/or accountability for the use of explosives and the development, implementation or maintenance of this NMP.

The Mine Manager is responsible for nitrogen management and source control at Brucejack. The Mine Manager works with Mine Operations and the Environment Manager to ensure appropriate N source control procedures are identified and implemented. Underground mining personnel are responsible to implement approved procedures and corrective actions for explosives handling and N source control, and to prepare the blast and waste disposal records outlined in this NMP. Environment Department staff conduct explosives use audits, collect and evaluate monitoring data to detect trends in nitrogen export arising from explosives use, and prepare internal and external summary reports of the NMP metrics and trends.

The tracking and reporting relevant to N management are summarized in Table 9-2. Regulatory reporting of NMP monitoring is not required. However, the records must be maintained and provided for regulatory review if requested. A summary of the NMP monitoring data is provided on an annual basis in the Brucejack Mine Annual Report.

Table 9-2: Summary of NMP Monitoring and Reporting

Review/Report	What is monitored
Blast Report (Daily)	Drilling/blasting records for a given pattern • Hole depth, explosives use, blasted volume/advance • Other activities (*i.e.,* shotcrete, water management, spills, etc.)
Waste Disposal Report (Daily)	Waste rock placement records • Underground rock volumes deposited to the WRTSF
WTP Report (Daily)	Daily performance and effluent quality • report on key performance metrics for WTP operation • metrics include nitrite monitoring
WTP Summary Review (Monthly)	Monthly performance review • Year to date summary of reagent usage, influent and effluent volumes, and internal water quality results
NMP Quarterly Review (Quarterly)	Year to date summary of NMP metrics • Informal internal review summarizing N loading rates, PF, BJ 3.10 results, external laboratory results for influent and effluent and blast audit findings • Comparison of modelled to actual quantities for excavation, as well as the deposition of waste and tailings to the WRTSF. • Flag emerging issues • Update progress on past issues
Annual Report	Annual summary of NMP monitoring metrics, N source control and loading rates • Annual summary of NMP monitoring data • Mine water, waste rock, ore, tailings, WTP Effluent and BJ 3.10 • Included in the annual water quality report

9.8 Management Review

The overall implementation and effectiveness of the NMP is reviewed quarterly by the Mine Manager and Environment Manager, with the review led by the staff Hydrogeologist/Hydrogeochemist. Reviews include monitoring records, nitrogen audits and an overall evaluation of the implementation of the NMP. Action items arising from the review process are assigned to the appropriate individuals and tracked for future evaluation.

10 CONCLUSIONS

Nitrogen Source Control Practices implemented at the Brucejack Mine have thus far kept Nitrogen levels at, or below, expected values. This version (version 5) of the Nitrogen Management Plan provides updated data for 2022, as well as detailing Nitrogen Management Plan changes, updates and best practices underway and planned for Brucejack Mine. Some of these activities included:

- Changes to drilling equipment and data management practices that have resulted to changes in how the development and production PFs are calculated;
- Changes to procedure for monitoring nitrogen (N) Loading from waste rock deposition by incorporating a 2 year averaging period to obtain more representative and normalized results; and

- Conducting N surface source control audit results within the NMP to summarize audit findings and corrective actions.

In terms of performance, recent data continues to illustrate good N source control, with:

- Nitrogen loading rates to mine water and ore that are in line with expected values; and,
- Water quality measurements of Nitrogen species at BJ 3.10 aligned with, or below expected values and permit conditions.

Planned improvements to N source control procedures in 2023 include:

- Continued training through presenting the NMP and Source Control Measures to the entire underground workforce in 2023; and
- Updating management trigger values for the Development and Production PFs based on changes to stope volume calculations, drilling methodology/equipment, blast pattern design and on-site reporting methods coupled with continued data evaluation.

APPENDIX A – SURFACE BLASTING N SOURCE CONTROL CONSIDERATIONS

Surface Blasting Explosives Use - Nitrogen Source Control Considerations [1]	
Explosives quality, storage and record keeping	- Explosives shall be manufacturer certified, stored according to manufacturer specifications, and be used prior to the expiry date. - Explosives certificates and/or test results shall be provided to Pretium.
Pattern design and record keeping	- Blast pattern design must use minimum quantity of explosives required to meet fragmentation objectives. - Pattern as-built design, explosives type and quantity, detonator type, booster type and placement, volume of rock blasted, miss holes, incompletely detonated holes, and presence of water shall be recorded for each blast. - These records shall be provided to Pretium within 24 hours of each blast.
Wet site conditions	- Water must be directed away from boreholes. - Dewater wet boreholes prior to loading. - Use explosives appropriate for wet conditions (i.e., emulsion) when water is present in the pattern or boreholes.
Powder column contamination	- Procedures must be implemented that prevent water, sediment and drill cuttings from entering the blast hole at any time.
Fractures and voids	- Decking and stemming can be used to isolate fractures and voids.
Stemming materials	- Stemming material should be angular coarse crush with a size approximately 1/5th to 1/8th of the blast hole diameter. - Drill cuttings may not be used for stemming.
Spills and record keeping	- The date, time, explosives type and quantity of all spills shall be recorded and reported to Pretium immediately. - Water shall not be used to wash away spilled explosives. - All spilled explosives shall be collected.
Disposal	- Waste explosives must be returned to manufacturer for disposal or detonated during a blast.

[1] Adapted from: Brucejack Mine Project Nitrogen Management Plan Revision 1, November 10, 2016.

APPENDIX B - UNDERGROUND BLASTING N SOURCE CONTROL CONSIDERATIONS

There are numerous considerations for underground blasting that may either enhance or reduce explosive consumption efficiency. Outlined below are typical considerations for improving explosive consumption efficiency and reducing the amount of residual nitrogen compounds available for waterborne export from the mine site.

Consideration	Description
Pattern design	The blast pattern should be designed to meet rock fragmentation objectives considering specific pattern geometry and geo-mechanical rock properties. The PF target is based on the minimum amount of explosive required to meet the fragmentation objectives.
Wet site conditions	The presence of water in the blast face creates challenging blast conditions that affect the amount of nitrogen released to the environment. Explosives appropriate for wet conditions must be used (i.e., AN-emulsion).
Explosive quality	Poor explosive quality (i.e., out of specification composition) may cause inefficient consumption, and in extreme cases failure to detonate, leading to poor blast performance and increased residue of nitrogen compounds.
Powder column contamination	This occurs when water or sediment (i.e., drill hole cuttings) are mixed into the powder column during blast hole loading. Sediment and water can cause bridging when one part of the powder column is separated from the remaining powder column, thereby preventing propagation of the explosion reaction through the column.
Fractures and voids	Loading explosives into boreholes with fractured rock or voids will result in explosives loading of empty spaces adjacent to the blast hole. Explosives connected to the powder column but confined to small spaces will deflagrate leading to the formation of yellow/orange smoke (nitrous oxides).
Detonation Failure	The powder column will not detonate if the detonator and booster are outside of the explosive or if the detonator chord is cut prior to detonation.
Spills	Spills can occur at the blast face due to leakage from the blast hole or by dripping out of the hose as the hose is moved between blast holes. All spills must be removed prior to blasting. Waste explosive must be collected before and after detonation to minimize N loss to the adit water and muck pile.

APPENDIX C – NITROGEN CONVERSION PROCESSES

1 PURPOSE

This appendix provides an overview of the nitrogen cycle, highlighting the key microbially-mediated nitrogen (N) conversion reactions and the reactions associated with N-based explosives. This overview is followed by a summary of water quality observations in the Waste Rock and Tailings Storage Facility (WRTSF) which are used to assess nitrogen conversion processes currently active in the WRTSF. Together this information is used to inform N management decisions at the Brucejack Mine (Brucejack).

2 NITROGEN REACTIONS IN THE ENVIRONMENT

2.1 Overview

In aqueous systems, nitrogen is stable as ammonia (as NH_3 or NH_4^+), nitrite (NO_2^-) and nitrate (NO_3^-) as well as dissolved nitrogen gas (N_2). The relative distribution of nitrogen between ammonia, nitrite and nitrate can shift according to the reduction-oxidation (redox) conditions of the water. Under oxidizing conditions, characterized by the presence of dissolved oxygen (oxic), nitrate is favoured. Whereas under reducing conditions, when dissolved oxygen is absent (anoxic), ammonia and nitrogen gas are favoured as shown in Figure 2-1.

Figure 2-1: Distribution of nitrogen species based on the reduction-oxidation potential (p*E*) of the aqueous system. Oxidizing conditions (positive p*E*) favour NO_3^- as the dominant N species, whereas reducing conditions (negative p*E*) favour conversion of NO_3^- to NH_3 and N_2. (Image credit: Stumm W. And Morgan J.J., 1981. Aquatic Chemistry: An Introduction Emphasizing Chemical Equilibria in Natural Waters, second edition).

The distribution of nitrogen species in the environment is also regulated by micro-organisms which convert nitrogen through various processes. These processes include nitrogen fixation, ammonification, nitrification, denitrification, anammox and dissimilatory nitrate reduction to ammonia (DNRA) (Figure 2-2). Together these processes and the associated chemical reactions (Table 2-1) comprise the N biogeochemical cycle which recycles nitrogen throughout the atmosphere and hydrosphere.

Figure 2-2: The microbially-mediated nitrogen biogeochemical cycle showing the inter-relationship between ammonification, nitrification, denitrification, annamox and dissimilatory nitrate reduction to ammonia (DNRA) processes. (Image credit: Bernhard, A. (2010) The Nitrogen Cycle: Processes, Players, and Human Impact. Nature Education Knowledge 3(10):25).

Table 2-1: Nitrogen cycling processes and corresponding chemical reactions.

Nitrogen Cycling Process	Chemical Reaction
Ammonia oxidation	$NH_3 + O_2 \rightarrow NO_2^- + 3H^+$
Ammonification	$N_2 + 8H^+ + 6e^- \rightarrow 2NH_4^+$
Ammonium nitrate dissolution	$NH_4\ NO_3 \rightarrow NH_4^+ + NO_3^-$
Anammox	$NH_4^+ + NO_2^- \rightarrow N_2 + 2H_2O$
Denitrification	$5\{CH_2O\} + 4NO_3^- + 4H^+ \rightarrow 5CO_2 + 2N_2 + 7H_2O$
Dissimilatory nitrate reduction to ammonia (DNRA)	$2\{CH_2O\} + NO_3^- + 2H^+ \rightarrow 2CO_2 + NH_4^+ + H_2O$
Nitrification	$2NH_3 + 3O_2 \rightarrow 2NO_3^- + 6H^+$
Nitrite oxidation	$2NO_2^- + 2O_2 \rightarrow 2NO_3^-$

Nitrogen in the form of ammonia and nitrate is often the limiting element for plant growth. Nitrogen gas is relatively inert and unreactive; however, certain organisms have adapted to convert nitrogen gas to ammonia through the nitrogen fixation process. Once nitrogen has been "fixed", it is available to be assimilated by plants and can be converted into organic forms such as amino acids and proteins.

As organisms die, microbial decomposition produces ammonia through the ammonification process. Conversely, nitrification is the process by which organisms convert ammonia to nitrite and nitrite to nitrate. Nitrification is favoured under oxic (i.e., presence of oxygen) conditions. Nitrate is converted back into nitrogen gas under anoxic to suboxic conditions when denitrification processes convert nitrate to nitrogen gas with nitrite as an intermediary product. Simultaneous anaerobic ammonium oxidation (anammox) processes can occur that combine ammonia and nitrite to nitrogen gas. These conditions are also conducive to DNRA processes that produce ammonia.

The discussion in following sections provides additional details on the nitrification and denitrification processes since these processes are most relevant to N in the WRTSF.

2.2 Nitrification (Oxidation) Reactions

Nitrification reactions in the natural environment (Table 2-2) are mediated by nitrifying organisms that are ubiquitous in groundwater, lakes and streams (Ward 2013; Ward *et al.*, 2011). These reactions typically occur under circum-neutral oxidizing conditions with the reaction rates for conversion of ammonia to nitrite and nitrite to nitrate increasing with increasing temperature and ammonia concentration.

Although the conversion rates are expected to be slower in cold-water systems, studies have shown that nitrification is active in cold-water northern lakes (Small *et al.*, 2013; Clevinger, 2013). The WRTSF is deep cold-water, circum-neutral and oxic throughout the water column. The entire water volume is exchanged over approximately 12 to 18 months. Conditions are conducive for the growth of nitrifying organisms throughout the water column, and the long residence time allows time for nitrification to occur. Based on observations of water quality, ammonia and nitrite oxidation processes are inferred to be active in the WRTSF throughout the water column (see Section 4).

Table 2-2: Key environmental factors influencing nitrification processes in cold water lakes

Environmental Factor	Description
Temperature	• In general, microbial growth rates and nitrification rates decrease with temperature; • Nitrification has been observed in lakes at 1 to 2 degrees C.
pH	• pH influences substrate and nutrient availability, affecting microbial growth rates; o low pH converts NO_2^- to HNO_2; HCO_3^- to H_2CO_3; o high pH converts NH_4^+ to NH_3; HCO_3^- to CO_3^{2-}. • Nitrification occurs over a range of pH, although circum-neutral conditions are favoured nitrification has been observed to occur as low as pH 3
Dissolved oxygen	• Oxygen is required for microbial growth • Below 0.5 mg-O_2/L dissolved oxygen there is little or no nitrification; • Nitrification consumes oxygen: o NH_4^+ to NO_2^-: 3.4 mg-O_2/L per mg-N/L; • NO_2^- to NO_3^-: 1.1 mg-O_2/L per mg-N/L.
Light	• Nitrifying bacteria are photosensitive and inhibited by ultraviolet light
Phosphorous	• Phosphorus is required for microbial growth; • Trace levels are sufficient to sustain nitrification in low nutrient lakes.
Substrate (Ammonia and Nitrite)	• Substrate is required for microbial growth; • Ammonia and nitrite oxidation rates are dependent on microbe populations; • Increase in substrate stimulates microbial growth and increases the nitrification rate; • Lack of substrate limits microbial growth, reducing the nitrification rate.
Chemicals	• High levels of heavy metals, inorganic and organic compounds may reduce microbial growth;

Note: Information compiled from: Bollmann *et al,* 2002; Kaplan *et al.*, 2000; Jeschke *et al.*, 2013, Clevinger, 2013; Small *et al.*, 2013; Anthonisen *et al.*, 1976.

Nitrification reactions in the WRTSF are expected to proceed throughout life of mine; however, nitrifying organisms are sensitive to environmental conditions and thus it is critical for monitoring data to be collected on a regular basis to assess any changes in these conditions. The interruption of nitrification processes can lead to accumulation of NH_3 or NO_2^-, or both. Some of the key environmental factors influencing nitrification processes are summarized in Table 2-2.

2.3 Denitrification and Reduction Processes

Denitrification processes are mediated by organisms that use ammonia, nitrite and nitrate as an energy sources and require organic carbon as a source of electrons for the reduction reactions. These conversion processes occur in anoxic or suboxic waters, and under mildly reducing to mildly oxidizing conditions. Other organisms mediate other conversions that can occur under these conditions such as conversion of nitrate to ammonia (DNRA), or ammonia to nitrogen gas (Anammox). The chemical equations for these processes are presented in Table 2-1, above.

Conditions that would support the growth of denitrifying, DNRA or Anammox organisms are not expected to occur in the WRTSF; however, should suboxic or anoxic zones develop and persist, the accumulation of ammonia may occur due to the interruption of nitrification processes. Denitrification and other nitrogen conversion processes could also occur within these zones leading to conversion of nitrate to nitrogen gas or ammonia, or both, as well as conversion of ammonia and nitrite to nitrogen gas.

3 NITROGEN FROM EXPLOSIVES

Ammonia and nitrate constitute the primary reactive ingredients in mining explosives. When detonated, the ammonia and nitrate combine to form nitrogen and other gases in an explosive reaction. Significant quantities of explosives are consumed during active mining and blasting residues can release nitrogen compounds to contact waters. In the ideal ammonium nitrate explosion reaction only gaseous nitrogen, oxygen and water are produced:

$$NH_4^+ + NO_3^- \rightarrow N_2 + 2H_2O + \frac{1}{2}O_2$$

However, in practice the explosion reaction converts less than 100% of the nitrogen to nitrogen gas with the remaining amounts as other nitrogen containing gases (*e.g.*, ammonia, nitrous oxides) that condense on blasted surfaces, ultimately entering contact water as ammonia, nitrite and nitrate.

4 NITROGEN MONITORING RESULTS FOR THE WRTSF

4.1 Monitoring Program

Water quality and flows are routinely monitored for mine dewatering and WRTSF discharge. Additional site investigations were conducted in 2016 through 2018 to characterize water quality throughout the water column. The water quality data indicate that microbially-mediated nitrification processes are active in the WRTSF, with higher proportions of nitrate observed in water from the

outlet as compared to mine water discharged to the WRTSF. The following sections summarize the data collected for mine water, the water column (BJ 35) and the WRTSF outlet (BJ 3.10).

4.2 Mine Water

During and after blasting, explosives residues are transferred to mine water from spraying and water accumulations in muck piles (blasted rock) on the mine floor. The blasted waste rock is then excavated and deposited in the WRTSF. Mine water is considered a proxy for the distribution of nitrogen species on waste rock surfaces, although this is complicated by recycling of treated WTP effluent to the underground mine for dust suppression.

Mining rates increased significantly in early 2016, therefore data from the 2016 to 2018 period were evaluated. As expected, concentrations of ammonia, nitrite and nitrate in mine water have increased in tandem with mining rate increases (Figure 4-1). From 2016 through 2018, nitrate ranged from approximately 5 to 60 mg-N/L. Ammonia and nitrite ranged from approximately 2 to 25 mg-N/L, and 0.5 to 6 mg-N/L, respectively.

The distribution of nitrogen species is shown in Figure 4-2. Overall, the proportional distributions of nitrate, ammonia and nitrite were relatively stable during the 2016 to 2018 period (approximately 70%, 25% and 5%, respectively). The monitoring data indicate the majority of the nitrogen added through waste rock deposition is in the form of nitrate with a significant proportion also present as ammonia.

Figure 4-1: Mine water concentrations of total nitrogen, nitrate, ammonia and nitrite from October 2014 through November 2018.

Figure 4-2: Proportional distribution of N in the form of nitrate, ammonia and nitrite in mine water from October 2014 through November 2018.

4.3 WRTSF Water Column (BJ 35)

The WRTSF water quality was periodically studied from 2016 to 2018 at station BJ 35, which is located in the vicinity of the deepest area of the WRTSF. Field parameters throughout the water column at this station were monitored using a profiling CTD configured with depth, temperature, pH, conductivity, dissolved oxygen and turbidity sensors. Water quality grab samples were collected annually in September with a Niskin grab sampler at variable depth intervals spanning 2 m below the surface to the bottom. The nitrogen species data are summarized and discussed below.

Based on the data sets acquired between 2016 and 2018, the WRTSF is stratified in September with two distinct layers. The surface layer is warm (approximately 6 to 9 °C) with variable depths ranging from approximately 5 to 15 m below the surface (Figure 4-3). The temperature of the cooler deep layer was generally uniform to the bottom (approximately 3.5 to 5.5 °C). The stratification of the WRTSF at this time of year is reflected in the shift in temperature, conductivity and dissolved oxygen concentrations that mark the depth boundary between the surface and deep layers (Figure 4-3).

The WRTSF water column was oxic during the study period but showed variable saturation levels from year to year. In September 2016 and 2017 dissolved oxygen saturation levels ranged from approximately 40% to 80% throughout the water column. In 2018 the dissolved oxygen levels were at approximately 80% saturation in the surface layer but ranged from approximately 5% to 20% saturation in the deep layer, lower than previous years. The decline in dissolved oxygen saturation is attributed to the temporary suspension of waste rock deposition for several months prior to monitoring in September 2018. Waste rock deposition is thought to pull oxygenated surface waters to depth as the waste rock descends through the water column, providing a continuous supply of oxic

water from the surface layer to the deep layer during waste rock deposition, which typically occurs continuously between the natural turnover mixing periods that occur twice annually (typically in June and September).

In all data sets, the concentration of nitrogen species generally decreased from the bottom to the surface, as shown in Figure 4-4, and stratification is reflected in the shift in nitrogen species concentrations between the surface and deep layers of the WRTSF. This observation is consistent with the expectation that inputs of nitrogen species from tailings and waste rock will initially accumulate at depth, due to the density induced by the TSS associated with these discharges, before slowly mixing upwards in the water column.

Nitrogen is dominantly present as nitrate, the nitrification end-member. Nitrate concentrations ranged from approximately 2 to 4 mg-N/L in the surface layer and from approximately 2 to 8 mg-N/L in the deep layer. In 2017 and 2018, ammonia concentrations showed a wide range from surface to depth, from approximately 0.01 to 0.65 mg-N. The lower ammonia concentrations at shallower depths relative to the bottom are attributed to nitrification processes that convert ammonia to nitrate as the bottom waters mix upwards. Nitrite concentrations, ranging from 0.005 to 0.025 mg-N/L, were relatively low at all measured intervals, indicating that ammonia oxidation is likely the rate limiting step for nitrification in the WRTSF.

Figure 4-3: Water column temperature, conductivity, turbidity and dissolved oxygen measured with a profiling CTD each September from 2016 through 2018.

Figure 4-4: Proportional distribution of ammonia, nitrite and nitrate measured in water column grab samples collected at specific depths each September from 2016 through 2018 (indicated by the plot symbols).

4.4 WRTSF Outlet (BJ 3.10)

Nitrogen at the BJ 3.10 is dominantly present as nitrate (typically >95% of all N present) with the balance present as ammonia and nitrite (Figure 4-5). Assuming that the mine water N distribution is representative of all N inputs to the WRTSF, with approximately 70% of N in the form of nitrate, then the observed enrichment of nitrate at BJ 3.10 may be attributed to nitrification processes in the WRTSF.

From August 2017 through February 2018 the proportion of N as ammonia increased from less than 1% to approximately 7% of all N at BJ 3.10. It is speculated environmental conditions were influenced by the discharge of tailings which began July 2017. This new discharge may have led to a temporary interruption of nitrification processes while the nitrifying organisms acclimatized to a slight change in conditions prior to resuming growth.

Figure 4-5: Proportional distribution of N in the form of nitrate, ammonia and nitrite at the BJ 3.10 from January 2016 through November 2018.

APPENDIX D - PREPARATION OF NMP METRICS

1 INTRODUCTION

The calculations used to derive Nitrogen Management Plan (NMP) metrics from monitoring data and records are described below. The NMP metrics should be updated on a monthly basis, including updates to plots used for NMP performance monitoring, similar to those presented in Section 7 of the NMP. Explosives use, nitrogen loading rates and nitrogen speciation are derived and compared to trigger values. Additional metrics not described below are derived as needed to aid with investigations or reporting.

2 EXPLOSIVES USE

Explosives use rates are monitored to evaluate source control measures. Good N source control is achieved when explosives use is similar to design values. Explosives use is monitored by calculating the powder factor (PF), which is equivalent to the amount of explosives (kg) used to blast a tonne of rock. Waste rock and ore blasted, and explosives use for each, are recorded on a daily basis by blasting crews and mine engineers. A monthly powder factor plot for ore (production) and waste (development) blasting is prepared, similar to NMP Figure 8-1.

3 MINE WATER

Nitrogen loads are transferred to mine water after a blast, therefore monitoring mine water N loading can indicate if excessive explosives loss is occurring during blasting. The total nitrogen (T-N) water quality parameter provides a non-specific measure of inorganic and organically bound N and is used with mine dewatering flows to estimate monthly N loads in mine water, per Equation 1.

Equation 1: $N = C_{mw} * Q_{mw} * 0.001 - C_{fw} * Q_{fw} * 0.001$

where:

N = Monthly N load (kg-N)
C_{mw} = Monthly average mine water T-N concentration (mg/L)
Q_{mw} = Monthly mine water volume (m^3)
C_{fw} = Fire/fresh water tank T-N concentration (mg/L)
Q_{fw} = Monthly flow directed from the fire/fresh water tank to the water box (m^3)

The monthly mine water loading rates are determined using the monthly N load (N) and the total tonnage of ore and waste rock blasted for the month, per Equation 2. A monthly loading rate plot is similar to NMP Figure 8-2 is updated.

Equation 2: $LR_N = \frac{N}{T}$

where:

LR_N = Monthly N loading rate per tonne of blasted rock (kg-N/t)
N = Monthly N load (kg-N)
T = Monthly blasted rock tonnage (t)

4 ORE

Ore is first processed in the SAG mill. At this stage water is added and the resulting slurry is ground to reduce the ore particle size. Nitrogen species are assumed to transfer entirely from the ore to the water in the slurry. The N loading rate for ore can be derived from water quality and flow data collected at the SAG mill.

The N load attributable to ore is derived from SAG mill water quality data, and instantaneous ore and process water feed rates. The change in the process water T-N concentration is calculated for each sampling event, as per Equation 4:

Equation 3: $\Delta C_N = C_{N-SAG\ Mill\ Discharge} - C_{N-SAG\ Mill\ Influent}$

where:

Δ CN = Change in T-N concentration (mg/L)
$C_{N\text{-}SAG\ Mill\ Discharge}$ = T-N concentration of SAG Mill discharge (mg/L)
$C_{N\text{-}SAG\ Mill\ Influent}$ = T-N concentration of SAG Mill influent (mg/L)

The SAG Mill influent feed rate (m^3/hr), ore feed rate (t/hr) and ΔC_N are used to calculate an instantaneous N load from ore using Equation 4 to calculate the ore N loading rate, and the ore N loading rate plot similar to NMP Figure 8-3 is updated.

Equation 4: $LR_{Ore} = \Delta C_N * 0.001 * \frac{FR_{pw}}{FR_{ore}}$

where:

LR_{Ore} = Loading rate per tonne of ore
Δ CN = Change in T-N concentration (mg/L)
FR_{ow} = Process water feed rate (m^3/hr)
FR_{ore} = Ore feed rate (t/hr)

5 TAILINGS

Tailings are discharged to the WRTSF bottom and N loads from tailings to the WRTSF are monitored. Tailings discharge flows and supernatant T-N concentration is used to estimate monthly N loads in tailings per Equation 5, and the N loading rate for tailings using Equation 2. The tailings N loading rate plot similar to NMP Figure 8-4 is updated.

Equation 5: $N = C_{SN} * Q_{SN} * 0.001$

where:

N = Monthly N load (kg-N)
C_{SN} = Tailings T-N concentration (mg/L)
Q_{SN} = Monthly supernatant volume (m^3)

6 WTP EFFLUENT

WTP effluent contains N loads transferred from all sources within the mill, the underground mine and the contact water system. WTP effluent accumulates N as it is recirculated during low flow months, when effluent is retained for use in ore processing and underground dust suppression. Concentrations of T-N in WTP effluent is used with WTP discharge flows to the WRTSF per Equation 5.

7 NITROGEN SPECIATION AND CONCENTRATION AT BJ 3.10

The concentrations and relative proportions of N species (ammonia, nitrite and nitrate) are monitored at BJ 3.10. The concentrations are compared to trigger values and discharge limits and plots similar to those in NMP Figure 8-7 are updated. The relative proportions of N species in mine water, tailings supernatant and at the WRTSF outlet (BJ 3.10) are derived by dividing the parameter concentration (as mg-N/L) by the sum of NH_3, NO_2^- and NO_3^- (as mg-N/L) and converting the ratio to a percentage. The proportion of T-N is compared to the sum of the N species to confirm that the N budget in the mine water is balanced. Monthly average T-N concentration at BJ 3.10 is used with BJ 3.10 discharge data to calculate the mass of N exported from the WRTSF per Equation 5.

8 WASTE ROCK

The N load from waste rock is back-calculated from the measured WRTSF N inventory and the N loads attributable to WTP effluent, STP Effluent and tailings. The waste rock N loading rate is back-calculated for the waste rock added to the WRTSF during the deposition period.

The WRTSF N inventory is derived from mass calculations for layers defined by the depth of each sample. The layer volume is estimated from a theoretical fill curve calculated from annual bathymetry surveys of the WRTSF. The layer volume and the corresponding T-N concentration are used in Equation 5 to calculate the N mass in each layer and the total WRTSF N inventory. The N exported from BJ 3.10, as described in Section 8, is added to the WRTSF inventory, and the previous N inventory is subtracted to derive the N load added to the WRTSF during the current period.

The N load terms are combined in Equation 6 to calculate the N load from waste rock. The N contributions from background input and NPAG quarry runoff are not measured and are therefore conservatively included the waste rock N load term.

Equation 3: $N_W = N_I + N_D - N_{WTP} - N_{STP} - N_T$

where:

N_W = N load (kg) attributed to waste rock
N_I = N inventory (kg) in the WRTSF
N_D = N load (kg) measured in the WRTSF discharge
N_{WTP} = N load (kg) measured in the WTP effluent
N_{STP} = N load (kg) measured in the STP effluent (treated domestic wastewater)
N_T = N load (kg) measured in tailings

The period waste rock N loading rate is determined using the period N load (N_w) and the total tonnage of waste rock placed in the WRTSF during the period, per Equation 2. The period loading rate plot similar to NMP Figure 8-5 is updated.

GLOSSARY AND ABBREVIATIONS

Terminology used in this document is defined where it is first used. The following list will assist readers who may choose to review only portions of the document.

EMA	*Environmental Management Act*
EWS	Eco Waste Solutions
HWR	*Hazardous Waste Regulation*
IOMM	Installation Operation and Maintenance Manual
KTA	Knipple Transfer Area
PLC	Programmable Logic Controller
Pretium	Pretium Resources Inc.
RIMP	Refuse Incinerator Management Plan
SOP	Standard Operating Procedure

1 PURPOSE

Environmental Management Act (EMA) Air Permit 107025 (PA-107025) authorizes Pretium Resources Inc. (Pretium) to operate two auxiliary fuel fired refuse incinerators throughout the life of the Brucejack Mine. The incinerators are operated in accordance with the Refuse Incinerator Management Plan (RIMP), as per Sections 11.7.7 and 4.5 of PA-107025. The purpose of this management plan is to provide direction on and methods for:

- measures to avoid potential wildlife attraction to the refuse incinerator area;
- a sampling and analysis plan for the waste oil burned;
- a tracking system to document the types and amounts of waste incinerated;
- a performance monitoring component including temperature readings; and
- an operational component describing how the operators will be trained and operate the refuse incinerators.

2 PERFORMANCE OBJECTIVES

The objectives of the RIMP are to manage and operate the incinerators for optimal performance and to track and monitor data and information required to comply with the conditions in PA-107025 for the Brucejack Mine.

3 SCOPE

The RIMP applies to the incinerator located at Brucejack Mine and the incinerator located at the Knipple Transfer Area (KTA), during all phases of the mine, until no longer required and facilities are decommissioned.

4 RELEVANT LEGISLATION, REGULATIONS AND EAC CONDITIONS

4.1 APPROVALS

Pretium is currently authorized to discharge contaminants to the air and ash to the ground from incinerators operated as part of the Brucejack Mine as per PA-107025 issued on January 9, 2014 (amended March 27, 2018 and July 8, 2021).

4.2 RELEVANT ENVIRONMENTAL ASSESSMENT CERTIFICATE CONDITIONS

Pretium was granted an Environmental Assessment Certificate (#M15-01) on March 26, 2015 that include a series of conditions associated with the Certificate. There are no conditions in the EAC that are required to be addressed within this plan.

4.3 RELEVANT DECISION STATEMENT CONDITIONS

Pretium was granted approval to proceed with the Brucejack Mine by the Government of Canada on July 30, 2015 in a Decision Statement that includes a series of conditions. There are no conditions in the Decision Statement that are required to be address within this plan.

4.4 RELEVANT LEGISLATION

Waste oil used to fuel the incinerators is analyzed quarterly and meets the specifications defined in Section 41(5) of Hazardous Waste Regulation (*HWR*) under the *EMA*.

4.5 ASSOCIATED MANAGEMENT PLANS

Management plans that support the activities associated with the RIMP include:

- Waste Management Plan;
- Wildlife Management Plan;
- Air Quality Management Plan; and
- Spill Response Plan.

5 ENVIRONMENTAL PROTECTION AND MANAGEMENT

5.1 INCINERATOR OPERATION

Optimal operation and performance of the incinerators is achieved through:

- management of the incineration process by trained personnel;
- operating the incinerator as per Section 6: Operating Instructions of the Installation, Operation and Maintenance Manual (IOMM) (Appendix A (Brucejack) & B (Knipple));
- incinerating acceptable waste products only, as defined in the permit and by the supplier ECO Waste Solutions (EWS) and for quantities as per the permit and the design of the incinerator; and,
- performing required maintenance as per Section 7: Maintenance Instructions of the Installation, Operation and Maintenance Manual.

5.1.1 Operator Responsibilities

It is the operator's role and responsibility to protect the environment by:

- complying with authorized discharge limits and operating practices specified in the permit to operate;
- minimizing emissions of particulate matter, HCl, toxic metals, carbon monoxide and organic compounds through proper incineration;
- operating the incinerator to generate high quality ash that is sterile (free of pathogens) and can be disposed of as per the permit;
- minimizing particulate matter emissions from ash handling;
- disposing of ash properly by sending it to the permitted disposal site; and
- performing regular maintenance inspections to identify deficiencies.

5.1.2 Operator Training

The incinerators are operated by individuals who have received training from the supplier, EWS. Operator qualifications include an aptitude for performing required equipment maintenance and operating the digital control panel. As the need for additional operators arises, they will be trained in-house by experienced operators. Future training by EWS will be supplied as required.

5.1.3 Waste Stream

Waste stream composition and quantity are important for the incinerator to operate properly. The solid waste material generated at the Brucejack Mine is typical of mixed camp non-hazardous solid waste consisting primarily of food-waste, kitchen waste including packaging, cardboard, wood waste and general refuse. The list of acceptable wastes as outlined in Section 5.1 of the Waste Management Plan, and also included in Section 6 of the Brucejack Installation, Operations and Maintenance Manual (Appendix A), is based upon guidance provided by EWS, and is supported by the waste segregation plan described in Section 5.2.4 of the Waste Management Plan. Waste is sorted at the source distinguishing waste designated for incinerator feed from other waste types. Waste is then transported directly to the incinerator or to the waste handling facility.

The following wastes will be limited in quantity:

- As per Section 1.7.5 of PA-107025 oil contaminated rags containing less than 3% of oil by weight may be incinerated provided they do not exceed 0.2% of the total waste incinerated per year;
- As per Section 1.7.6 of PA-107025 sewage sludge will be dewatered to a minimum of 25-30% solids content and comprise no more than 20% of the batch by weight; and
- As per operation specifications, kitchen grease and kitchen oils will be incinerated in limited quantities (up to a 2 ½ gallon pail) per batch.

The types of waste for each batch are weighed, using the scale that is housed within the incinerator building, and recorded. This prevents overloading the incinerator and promotes optimization of the waste feed characteristics for each batch, thereby contributing to effective and complete combustion.

The volume of waste per batch that each incinerator is design for is as follows:

- Brucejack Mine Site (Model: ECO M2TN WO): 1513 kg/batch/day plus up to 20 L/hour of waste oil.
- KTA (Model: CA100WO): 182 kg/batch; 364 kg per day plus up to 19 L/hour (5 gal/hour) of waste oil.

The incinerators were designed for the type and volume of waste mentioned above, and only those waste types and volumes are processed in the incinerator to maintain incinerator efficiency. Inappropriate materials including, but not limited to, reactive/explosive chemicals and items containing heavy metals, are not processed in the incinerator.

Waste oil used to fire the incinerators is collected at the source (i.e., maintenance facilities) in either containers less than 230 L capacity or in totes, which are transported to the incinerator and oil transferred to the incinerator waste oil tanks. Totes are either double-walled (i.e., Lube Pro totes with secondary containment built in) or placed in secondary containment when not in transport. Waste oil is burned as the first fuel of choice whenever available.

5.1.4 Optimal Operation

Section 6 of the Installation, Operation and Maintenance Manuals (Appendices A & B) provides Operation Instructions for each of the two incinerator types. Hard copies of these manuals are located at each incinerator facility.

Optimal operation of the incinerator depends on several factors, such as: composition and quantity of the waste, incinerator loading method and the temperature within the Secondary Chamber. The Secondary Chamber controls the temperature at 1000°C (1832°F), using a thermocouple, which constantly measures the temperature inside the chamber. The temperature readings are monitored by the system's programmable logic controller (PLC) and the PLC initiates operational changes such as increasing or decreasing the speed of the Secondary Chamber Blower and the output of the Secondary Chamber Burner.

Dewatered sewage sludge (bio solids) may be transported to the incinerator in sealed 20 kg to 25 kg heavy duty and combustible plastic bags. The sealed bags may be loaded into the primary incinerator chamber onto a layer of other solid camp wastes. The sewage sludge proportion does not exceed 20% of the batch by weight.

The solid waste, oily rags (if available), kitchen grease and dewatered sewage sludge are co-mingled to ensure that any wet low heat value waste is mixed with the other drier materials.

5.1.4.1 Sewage Sludge Handling

A prime rotary fan press is used to dewater the sewage sludge to a minimum of 25-30% solids content. The press, designed by FilterBoxx, is built to achieve the 25-30% solids content. A screw conveyor/feeder system is used to load the dewatered sewage sludge into reinforced plastic bags. Sludge contained in sealed bags may be transported to the incinerator, weighed and loaded into the incinerator at the appropriate time.

5.1.5 Incinerator Maintenance

Maintenance instructions for each incinerator are outlined in Section 7 of the Installation, Operation and Maintenance Manuals. Summary tables of preventative maintenance instructions are broken out into daily, weekly, monthly, quarterly, annual and 24-60-month maintenance procedures. Maintenance is performed by the operator or appropriate specialists.

5.1.6 Disposal of Ash

Adequately burned ash may be disposed of in the salvaged soil stockpile located at the KTA as per PA-107025. No large chunks of unburned waste material (other than metals or glass) should remain in the ash. Metals and glass that may be present after incineration, due to being missed in pre-segregation and sorting, will be removed prior to disposal. By following the manufacturer's operating

specifications, residual incinerator ash will be inert and non-toxic. The incinerator operator is responsible for efficient operation of the incinerator and a well- separated end-product.

Ash and waste residue from the incinerator are cooled and placed into tote for offsite disposal by 360 Environmental Solutions Ltd. or buried on site. Any runoff that might enter a burial site will be diverted away to prevent contact.

5.2 WILDLIFE PROTECTION

At the KTA, the incinerator building and waste handling facility building are enclosed within an electrified fence. At the Brucejack Mine, neither the building housing, the incinerator or the waste handling facility are planned to be fenced unless warranted.

Additional measures to minimize wildlife attractants are described in Section 5.2.5 of the Waste Management Plan and in Section 5.5 of the Wildlife Management Plan.

The onsite incinerators minimize the storage duration of kitchen wastes with burns scheduled either daily or every other day, depending on the number of people on site.

6 ENVIRONMENTAL MONITORING

6.1 PERFORMANCE MONITORING – TEMPERATURE

The integrated PLC in the Main Control Panel automatically monitors the entire incineration process and some system inputs are recorded and logged for record-keeping purposes, including temperature and pressure. Data can be transferred to storage by using the USB flash memory installed in the back of the HMI. Data from the incinerator that is logged automatically on the HMI will be manually retrieved from the HMI by the operator to create a record of temperature and pressure for reporting and inspection as required by PA-107025.

6.2 WASTE OIL ANALYSIS

Waste oil samples are collected and analyzed at a certified laboratory, as per Section 5.2 of PA-107025. Results are compared against the specifications defined in Section 41(5) of the *HWR* under the *EMA*.

HWR Section 41(5): A person must not, without approval, use waste oil as a fuel unless it meets the following specifications:

Table 6.2-1. Allowable metal and PCB concentrations in waste oil use as a fuel

Waste Oil Specifications for Use as a Fuel	
Column I Parameter	Column III Allowable Level for Fuel in Uses Other than for Cement Kilns
total arsenic	5.0 mg/L maximum
total cadmium	2.0 mg/L maximum
total organic halogens (as Cl)	1,500 mg/L maximum
total chromium	10 mg/L maximum
total lead	50 mg/L maximum
total polychlorinated biphenyls (PCB)	3.0 mg/L maximum

Samples are collected from the 1,000 L totes and other containers (less than 230 L) that are used to collect and transport waste oil. The Chain of Custody Record presented in Appendix C is used to record sampling events.

As per Section 5.2 of PA-107025, the frequency of the analyses is quarterly. Sample frequency may be reduced to annual provided Pretium demonstrates consistency in four consecutive quarterly results and that the content meets the requirements specified in Sections 1.7.4 (i.e. Section 41(5) of the *HWR* under the *EMA*). Should the annual results fail, Pretium must return to performing quarterly analyses.

6.3 SEWAGE SLUDGE ANALYSIS

Although sewage sludge solids are currently transported offsite for disposal, sludge may be incinerated provided Sections 1.7.6 and 5.2 of PA-107025 are met. Should sludge disposal via incineration be resumed, sludge samples will be collected quarterly to verify the PA-107025 criteria of 25-30% solid content is met. Upon demonstration that four consecutive quarterly results meet the requirements specified in Section 1.7.6, sample frequency will be reduced to annually. Should an annual result fail, Pretium will return to conducting quarterly analyses. Sludge samples are collected from the discharge hopper of the screw feeder while the transfer bags are being filled.

6.4 WORK PLANNING AND SCHEDULE

Monitoring frequency for temperature and pressure, waste oil and sewage sludge are outlined in Table 6.4-1.

Table 6.4-1. Monitoring Schedule

Monitoring	Frequency
Temperature & Pressure	Continuous
Waste Oil	Quarterly*
Sewage Sludge	Quarterly*

*Frequency may be reduced to annually as per Section 5.2 of PA-107025

7 REPORTING AND RECORDING

7.1 REPORTING

7.1.1 Compliance Reporting

7.1.1.1 Environmental Management Act Permit Reporting

Section 5.2.5 and 5.9 of PA-107025 require an annual assessment report be submitted to the BC Ministry of Environment. The report will include, but is not necessarily limited to, the following:

- summary of any non-compliance with the permit and remedial and preventative actions undertaken; include the copy of the Annual Status Report Form;
- summary of air quality and meteorological monitoring data obtained during the reporting period and interpretation of such data,
- summary of equipment performance monitoring data including continuous temperature and pressure recordings for the incinerators;
- summary of inspection and maintenance activities of the authorized works;
- results of analyses of waste oil used as fuel for the incinerators;
- results of lab analyses of sewage sludge for solids content;
- mass and percentage of sewage sludge per each batch of incineration;
- any new information or proposed changes relating to the authorized sources;
- summary of waste streams subject to incineration and open burning including annual quantification and waste storage methods.
- occurrences or observations of wildlife (medium and large carnivores) accessing waste, ash, or the incinerator area at the site; incidents of killing bears on the mine site due to potential concerns related to human-bear interactions; and mitigation measures taken;
- a statement regarding progress in reducing the waste stream, in accordance with the hierarchy of reduce, reuse and recycle principles.

The report will be submitted on or before March 31st of each year for the previous year's operations. Copies of this report will be sent to the Tsetsaut/Skii km Lax Ha First Nation, the Tahltan Central Council and Nisga'a Lisims Government.

7.1.2 External / Internal Reporting

Currently there are no other external/internal reporting requirements (i.e., reporting to advisory group or annual environmental report) identified for this management plan.

7.2 RECORD KEEPING / TRACKING

7.2.1 Waste Quantity and Composition

Wastes appropriate for incineration are sorted by type and weighed at the incinerator to assure the proper feed composition. The incinerator operators maintain a log of the waste composition and quantity for each batch incinerated. These records are kept at each facility and are made readily available in the event of an inspection.

7.2.2 Temperature and Pressure

Temperature and pressure data from the incinerator is logged automatically on the Human Machine Interface (HMI) and manually retrieved from the HMI by the operator to create a record. Data is downloaded weekly.

7.2.3 Monitoring Results

Pretium will assume the responsibility of data management and record-keeping of monitoring results. Data will be entered into suitable electronic databases and have quality control checks completed upon receipt of results. Data will be entered in a format and program that allows for comparison between quarters and will be stored in a single file format for each type of monitoring activity. Monitoring data will be stored for the life of the mine and be made available for review upon request.

The Chain of Custody Record form presented in Appendix C will create a record of sampling events.

7.2.4 Continuous Improvement, Follow-up, and Adaptive Management

If monitoring data are found to be out of compliance with permit conditions, adaptive management options will be assessed prior to implementation. The need for any corrective actions to reduce on-site emissions or install additional control measures will be determined on a case-by-case basis. Any modifications made to the plan, or any of the associated plans, will be communicated to regulatory authorities and First Nations where applicable.

7.2.5 Incident Response Records

Incident response records will be stored for a minimum of five years and made available for review upon request.

7.2.6 Permit Database and Amendments

The following permits related to refuse incineration are currently held for the Project:

- Environmental Management Act (2003) - Air Discharge Permit 107025 (amended July 22, 2015, July 12, 2016, November 5, 2017, March 27, 2018, and July 8, 2021).

Additional permit and permit amendments will be added on an as-needed basis.

General Description - Thermal Oxidation Concept

The **ECO M2TN WO** Incinerator system consists of a **Primary Chamber** and a **Secondary Chamber** (also known as the Afterburner). Both chambers are vessels constructed of steel with a special insulating liner known as refractory.

The **Primary Chamber** has a front door for loading of waste material and for the removal of residual ash.

The waste is loaded into the **Primary Chamber** until it is ¾ full. Once ¾ full the **Primary Chamber** is sealed and the combustion cycle begins. This type of system is known as *batch-fed* processing.

Primary Chamber

To begin the process of burning the solid waste, the **Primary Chamber Burner** is used to elevate the temperature of the **Primary Chamber** to ignite the waste. Once the **Primary Chamber** reaches a temperature of 650-850 ^{o}C (1200-1560 ^{o}F), by using a **Thermocouple** to measure the temperature of the **Primary Chamber**, the burn process becomes self-fuelling and the burner will shut off. To save fuel and control temperatures, only when the energy contained within the waste is depleted, will the burner periodically turn on.

The **Primary Chamber** operates under *controlled temperature* conditions. The amount of heat released, from the burning of the waste, is controlled by limiting the air into the **Primary Chamber** to less than what is required to complete combustion. This is described as *starved air* conditions. With controlled air and temperature the waste is dried, heated and burned thereby releasing moisture and volatile components. The non-volatile, combustible portion of the waste is burned in the **Primary Chamber** to provide heat while the non-combustible portion accumulates as ash. These conditions ensure that the waste is allowed to fully combust and is rendered sterile. In the end, the waste volume is reduced by over 90%.

Remaining in the **Primary Chamber** are non-combustibles, such as metal and glass, and carbonaceous residue. The incoming air, subjecting the non-combustibles to high temperatures, further burns the carbonaceous residue. The result is an oxidized ash product.

Controlling the gas velocity through the system is an important factor in limiting pollution. The gases flowing from the **Primary Chamber** are a result of the interaction of the air with the waste during the controlled burning process. Both the quantity and velocity of the gas product vary according to chamber temperature conditions and the type of waste being burned. The integrated controls for the **Primary** and **Secondary Chamber** act to minimize peaking activity thus controlling pollution automatically.

The combustion gases released in the **Primary Chamber** then pass into the **Secondary Chamber** through a turbulent mixing zone where ignition takes place and additional combustion air is provided to complete the burning process.

Secondary Chamber

As waste burns in the **Primary Chamber**, gases containing the products of combustion are pulled continuously into the high temperature zone of the **Secondary Chamber** where the oxidation reaction of the combustible products is completed.

The **Secondary Chamber** controls the temperature at 1000°C (1832 ^{o}F), using a **Thermocouple,** which constantly measures the temperature inside the chamber. The temperature readings are monitored by the system's PLC and the PLC will initiate operational changes such as increasing or decreasing the speed of the **Secondary Chamber Blower** and the output of the **Secondary Chamber Burner**.

The **Secondary Chamber Blower** air is introduced into the **Secondary Chamber** by an air ring manifold that surrounds the **Secondary Chamber**. The manifold has small air jets called tweers that open into the **Secondary Chamber** at the side walls and create a powerful vortex of excess air to mix the incoming gases and ensure complete combustion. The flow of air is tightly managed by the control system using a Variable Frequency Drive (VFD) to control the speed of the fan and modulating motors on the blower inlet dampers.

The **Secondary Chamber Blower** is extremely important as it creates the turbulence required to mix the gases and oxygenate them. This fosters the high efficiency combustion required to break hydrocarbon chains into carbon dioxide and water vapour. It also acts to cool the **Primary Chamber** and prevent temperature overruns.

Secondary Chamber Burner is similar to the burner used in the **Primary Chamber** except that it has a much higher output and it is self-modulated over a broad range for very precise temperature control.

The **Secondary Chamber** is sized to allow two seconds of retention time. This is the time that the gases from the **Primary Chamber** are retained in the **Secondary Chamber** before they exit to the next stage. Two seconds of retention is considered to be ideal to destroy any harmful organic hydrocarbons produced from the **Primary Chamber**.

Protecting the Environment

Why Incinerate

As society becomes more environmentally conscious, environmental regulations on the proper disposal of waste has become more stringent. As a result, incineration has become an environmentally responsible and socially acceptable alternative for handling waste at the point of need. However, incineration does not eliminate the need to landfill waste but it does reduce the amount of waste that must be placed in landfills.

Primary Advantages of incineration are:

- It greatly reduces the weight and volume of waste material that must be disposed of in landfills
- It destroys organic materials that may be harmful or that may be degradable to harmful materials in landfills

- The incinerator sterilizes the waste; that is, the high temperatures in incinerators can destroy any pathogens that may be in infectious waste materials
- The incinerator destroys animal or human pathological wastes that the general public finds objectionable to handle or see.

Environmental Concerns

The general public will not accept incineration as an option for treating waste of any kind, if they do not believe that it is safe environmentally. The primary concerns are about air pollutants produced by the incinerator and the toxicity of the residual ash.

Air Pollutants of Concern

Particulate matter may be defined as fine liquid or solid matter such as dust, smoke, mist, or fumes found in the gaseous emissions from the incinerator. Particulate matter emissions may have a dark or light color. Particulate matter emissions can be described in terms of opacity. Opacity is the degree to which light is obscured by a polluted gas (a clear window has 0 percent opacity while black paper has 100 percent opacity). Opacity may be measured with the naked eye or using an opacity monitor. Particulate matter is a problem because it can cause or aggravate respiratory problems in humans. It also creates aesthetic problems since it is readily noticed and is a nuisance because of soiling of exposed surfaces on houses and cars.

Hydrochloric HCl acid is generated when polyvinyl chloride (PVC) plastic (usually clear plastic) material is burned in the incinerator. The appearance of a white plume or cloud a short distance above the stack indicates that HCl is condensing. The major concerns about HCl are that it causes respiratory problems in humans, contributes to acid rain problems, and causes material damage to metals and concrete.

Toxic metals include cadmium, arsenic, beryllium, chromium, nickel, lead, and mercury. These metals may be found in municipal wastes. These metals are known to be hazardous to human health.

Organic compounds are compounds that contain primarily carbon and hydrogen and may also contain other elements such as oxygen, nitrogen, and chlorine in smaller amounts. Some organic compounds are known to cause or are suspected of causing cancer and are considered hazardous air pollutants. The public's primary concern is related to dioxin and furan emissions, but other organic compounds such as benzene and vinyl chloride may be emitted.

Carbon Monoxide (CO) also is generated during combustion if the combustor is not operated properly. (Your automobile generates some amount of CO.) CO is toxic to humans if concentrations are high enough, and it also is an indicator of combustion quality.

Solid Waste Ash Quality

One of the major objectives of incineration is to generate a high quality ash for land disposal. All pathogens should be destroyed, and almost all organic material should be completely burned. Ideally, no large chunks of unburned waste material (other than metals or glass) should remain in the waste. A measure of ash quality is "burnout," which is the percentage of organic material remaining in the waste. For example, a burnout of 95 percent means that the ash can contain only 5 percent organics. Adequately burned and quenched ash may be disposed of in a

sanitary (municipal) landfill. The ash should be stored in covered containers or kept wet prior to transport to the landfill to prevent 'fugitive \ emissions.' Individual landfills may have requirements that must be followed in order for your waste to be accepted. You should familiarize yourself with these requirements to prevent refusal of the waste.

The Operator – Your Role

It is the operator's role and responsibility to protect the environment by:

1. Complying with all emission limits and operating practices specified in the permit to operate.
2. Minimizing emissions of particulate matter, HCl, toxic metals, carbon monoxide, and organic compounds through proper incinerator;
3. Operating the incinerator to generate high quality ash that is sterile and can be disposed of in landfills;
4. Minimizing particulate matter emissions from ash handling;
5. Disposing of ash properly by sending it to appropriate disposal sites; and
6. Performing the regular maintenance inspections to catch any operational problems early.

Basic Combustion Principles

The Combustion Process

Combustion of MSW is a chemical reaction. In the incinerator, organic materials and oxygen react rapidly and violently to produce combustion gases and energy in the form of heat and light.

$$\text{Organic Solid Material + Oxygen} \xrightarrow[\text{Heat}]{} \text{Combustion Gas + Solid Residue + Energy(Heat)}$$

For the reaction to begin and to keep going, all three elements - organic material, oxygen, and heat-must be present. The organic material used in the reaction comes from two sources, waste and auxiliary fuel. Some organic material is contained in most solid waste types. Depending on the fraction of organics and the specific organic composition, the waste may be adequate to sustain combustion. Auxiliary fuel may be used to maintain combustion if the waste material does not contain enough organic material to maintain high temperatures. The combustion reaction between the organic material and oxygen that causes the organics to burn will occur only after the temperature of the organic material is raised to the point that combustion can begin.

Energy in the form of heat is required to raise the temperatures of the incinerator chamber and organic material and O_2. Initially, this energy usually is supplied by the pilot and auxiliary fuel burners. After the system is in full operation, the energy released from the burning waste often is adequate to maintain these high temperatures.

Fate of Combustion Air

The oxygen needed for the combustion reaction is supplied by the ambient combustion air. Combustion air is supplied to the combustion chambers through air ports by a forced draft fan,

by an induced draft fan, or by natural draft. In general, this air contains about 21 percent oxygen (O_2) and 79 percent nitrogen (N_2), so about 21 percent of the total combustion air fed to the incinerator is oxygen that is available to react with the organic material in the waste and fuel. The nitrogen passes through the chamber mostly unreacted; some nitrogen oxides are formed.

Oxygen Reaction

Solid waste contains two types of organic materials

1. Volatile Matter
2. Fixed Carbon

These two types of materials are involved in distinct types of combustion reactions, and the operating variables that control the two types of reaction are different.

Volatile matter is that portion of the waste that is vaporized (or evaporated) when the waste is heated. Combustion occurs after the material becomes a gas. The combustion variables that influence this reaction are gas temperature, residence time, and mixing.

- A minimum temperature is needed to start and sustain the chemical reaction.
- Residence time is the length of time, generally measured in seconds that the combustion gas spends in the high temperature combustion chamber. The residence time must be long enough for the reaction to be completed before it leaves the high temperature zone.
- Turbulent mixing of the volatile matter and combustion air is required to ensure that the organic material and oxygen are well mixed.

Fixed carbon is the nonvolatile organic portion of the waste. The combustion reaction is a solid-phase reaction that occurs in the primary chamber (although some materials may burn in suspension). Key operating parameters are temperature and solids retention time.

- The solids retention time is the length of time that the waste remains in the primary chamber.

Products of complete combustion are:

- Carbon dioxide
- Water

An example of volatile waste is backyard charcoal grill with starting fluid. The starting fluid is highly volatile. When put on the charcoal and ignited with a match, it rapidly volatilizes and burns. The charcoal contains less volatile matter and burns slowly as a fixed carbon bed.

Operating Factors Related to Combustion

The three operating factors that have the greatest effects on the combustion reaction are:

- Combustion airflow rate and distribution,
- Operating temperatures, and
- Waste feed rate and characteristics.

These three factors are all related. Controlling them controls the combustion reaction. The two key questions about combustion air are:

- How much combustion air is needed to sustain the combustion reaction?
- What happens if there is too much or too little combustion air?

Stoichiometric Air

In the chemical reaction between organic materials and oxygen, the amount of oxygen required under ideal or "perfect" conditions to burn all of the organic materials with no oxygen left over is the stoichiometric (or theoretical)-oxygen level. The amount of combustion air associated with that oxygen level is called the stoichiometric air level. At stoichiometric air level the combustion gas would contain no oxygen because it would all be used in the combustion reaction.

Substoichiometric Air

Airflows less than those required at stoichiometric levels are called deficient air or substoichiometric starved-air levels. Under starved-air conditions, the combustion gas would again contain no oxygen, but organics also would remain because combustion is not complete.

Excess Air

Air flows greater than those required at stoichiometric levels are called excess-air levels. Typically an incinerator operates with an overall 140 to 200 percent excess air level. That is, the incinerator operates with one and one-half to two times more air than required at stoichiometric levels. Excess air is used to assure that enough oxygen is available for complete combustion.

Control of Temperature as a Function of Air Level

Maximum combustion temperatures are always attained at stoichiometric conditions. As the amount of excess air is increased above the stoichiometric point, the temperature in the incinerator drops because energy is used to heat the combustion air. If the amount of combustion air is too great, the temperature drops below “good combustion temperature," and undesirable combustion products are generated as a result of incomplete combustion. As the amount of excess air is decreased, the combustion temperature increases until it becomes maximum at the stoichiometric point. Below the stoichiometric point, the temperature decreases because complete combustion has not occurred.

CONTROL OF TEMPERATURE AS A FUNCTION OF EXCESS AIR

The relationship of how combustion air level can affect temperature has just been shown. Temperature also plays an important role in the combustion of waste. Temperatures need to be maintained at levels high enough to ensure pathogen destruction and to sustain the combustion reaction. However, temperatures that are too high also cause problems. Continuous exposure of the combustor refractory to high temperatures is generally not desirable because it can cause the ash to fuse and can cause damage to the refractory.

Waste Characteristics

The primary characteristics of the waste that affect the combustion reaction are:

- The heating value
- The moisture content
- The chlorine content

Different wastes have different heating values and moisture contents. They will affect the combustion process.

The HEATING VALUE of a waste is a measure of the energy released when the waste is burned. It is measured in units of Btu/lb (J/kg). A heating value of about 5,000 Btu/lb (11.6×10^{-6} J/kg) or greater is needed to sustain combustion. Wastes with lower heating values can be burned but they will not maintain adequate temperature without the addition of auxiliary fuel. The heating value of the waste can be used to calculate total heat input to the incinerator where:

Heat Input (Btu/h) = Feed Rate (lb/h) x Heating Value (Btu/lb)

Heat input to the incinerator will affect temperature. More heat input yields higher temperature. Heat input also will affect air requirements; more air is required (1 SCF/100 Btu).

MOISTURE is evaporated from the waste as the temperature of the waste is raised in the combustion chamber. It passes through the incinerator, unchanged, as water vapor. Evaporation of moisture uses energy and reduces the temperature in the combustion chamber.

CHLORINE in plastics or solvents in the waste feed will react to form hydrochloric acid (HCl). This HCl can be an emission problem. It can create corrosion problems of the equipment downstream from the incinerator.

The heating value (Btu value) and moisture varies widely. Compare plastics (high Btu, no moisture) to Beddings, shavings, etc. to Anatomical

Summary of Key Operation Factors Affecting Combustion

1. Key factors are interrelated.
2. Air quality/distribution
3. Sufficient air for complete reaction
4. Distributed to promote mixing
5. Mixing
6. Assure contact of oxygen and organics
7. Temperature

8. High enough to sustain combustion
9. High enough to have complete reaction
10. Residence/retention time
11. Sufficient time to allow reaction to complete

Waste characteristics also are important

- Heating value
- Measure of energy released
- Heat input determines air required
- Moisture content
- Requires energy to vaporize water
- Chlorine content
- Affects HCl emissions

Products of Combustion Reaction

Complete Combustion

The primary products of waste incineration are:

- Combustion gases
- Solid residue (ash)
- Energy

The primary objectives of the combustion process are to generate an ash residue that is sterile (free of pathogens) and does not contain unburned, recognizable wastes; and to minimize air pollutants in the combustion gas stream.

The organic materials that enter the incinerator with the waste and fuel are primarily made up of carbon, hydrogen, and oxygen. Ideally, these organic materials react with oxygen in the combustion gas to form carbon dioxide and water vapor. The chemical reaction for this ideal situation is

$$\text{Organics} + O_2 + \text{Heat} \longrightarrow CO_2 + H_2O + \text{Heat}$$
(C, H, 0)

This ideal reaction represents complete combustion.

Incomplete Combustion

However, this ideal reaction does not occur in operating waste combustion systems. Factors that lead to a less than ideal reaction are poor mixing, too little combustion air, and low temperatures. Under those conditions products of incomplete combustion are emitted with the stack gases. The most common product of incomplete combustion is CO. Another product of incomplete combustion that often is emitted under poor mixing conditions or high temperature, low excess air conditions, is elemental carbon (or soot). The soot particles are very fine and generally result in high opacity at the combustion stack. Other products of incomplete combustion that cause concern because of their health impacts are hazardous organic

compounds such as benzene, dioxins, and furans. Although these compounds are not found in the waste, under incomplete combustion conditions they can be formed as intermediate combustion products.

The waste feed also includes inorganic materials; generally, they are not involved in the combustion reaction. The inorganic materials in the waste feed (ash) are either retained in the ash or are emitted as particulate matter in the combustion gas. Air velocities in the combustion bed are controlled to reduce the amount of inorganic material entrained (picked up by) the combustion gas and emitted with the combustion gas. If combustion is not complete, organics will remain in ash; this is typical…it is atypical to have 100 percent combustion of ash bed. Under poor conditions (low temperature, low turbulence in ash bed) the ash may have pathogens present, the ash may not be sterilized.

Combustion Indicators

The following indicators can be used to monitor combustion quality.

Opacity

The opacity of the combustion gas stream is a measure of the degree to which the stack gas plume blocks light.

- High opacities indicate high emissions.
- Opacity is primarily caused by noncombustible ash or uncombusted carbon (soot) in the flue gas.
- High opacities can indicate poor mixing or low levels of combustion air.
- High opacities also may be generated by high levels of HCl emissions or poor burner operation in the secondary chamber.

If a large amount of water vapor is present in the combustion gas, the water can condense when it cools as it leaves the stack forming a dense white "steam plume." This is not an indicator of poor combustion and should not be confused with a black or white smoke plume caused by soot or acid gases. Opacity can be visually determined by a person or measured by an instrument.

Other indicators which provide information about combustion conditions are measurements of the combustion gas oxygen and CO levels. However, these measurements require instruments and most facilities do not have those instruments.

Ash Quality

Visual appearance of ash can be an indicator of combustion problems. If an incinerator is operating properly, little organic material will remain in the ash. Whitish gray ash indicates better burnout and less carbon than black. The extent of organics combustion can be measured by the quantity of combustible materials remaining in the ash. Noted increases in combustibles in the ash indicate a combustion problem which may include bed temperatures that are too low, improper distribution of combustion air in the bed, or insufficient waste retention times.

NOTE:

Because the transformer is fused at 125% of the full load on the primary side, it doesn't require a circuit breaker in the secondary since every circuit has its own breaker. The main circuit breaker is not an electrical code requirement.

The distribution design shown is our standard and it is exclusive for the incinerator, no external equipment should be connected to this panel. We would like to keep the current design as the parts have been ordered and received and most of the layout has existing templates that makes our assembly easier and faster.

ECO WASTE SOLUTIONS

GENERAL ASSEMBLY & INSTALLATION INFORMATION

The **EWS Mobile Incinerator** is assembled with interconnections and external components to be mounted as required. Please review (section 4 on this manual) the Equipment Layout ECOM2TNWO-GA-rB and Piping ECO-M2TNWO P&ID prior to assembly.

Customer Responsibility

Provide all foundation work of packed gravel under the base frame and tanks. Provide electrical wiring between Main Disconnect Panel, Control Panel and Junction boxes. Connect provided electrical cables from Junction box associated Equipment as per Electrical wiring drawings where necessary. All electrical work is to be performed by Certified Electrician.

NOTE

a. **Fuel tanks should be out of the way and protected using bollards against accidental impact of mobile equipment (e.g. trucks, etc.)**

b. Foundation requirements between pads to be determined by customer

c. Specific location of incinerator to be determined by customer and site restrictions

- Install I-beams, spacers and equipment using a crane, forklift, come-a-longs, hydraulic jacks/hand-pumps, etc. Installation to be performed by qualified trades as per local code.
- Provide all utility services including connections to the equipment including fuel, electrical, air, etc. using basic hand tools. Installation of all Services to be performed by qualified local trades, as per local code.
- Provide proper protection of all equipment from accidental damage or vandalism (bollards, exterior lighting, etc).
- Perform any touch up painting and cleanup of equipment after assembly.
- Locate the fuel tank as per Equipment Layout to ensure maximum positive supply pressure on the suction side.
- Obtain any and all construction, operating and environmental permits and other approvals as may be required in the area of jurisdiction where the equipment is being deployed and operated prior to installation. EWS will assist in supplying technical information required for these permits to the customer as it relates to EWS equipment.
- Maintain ample space around all equipment for maintenance, cleaning and safety considerations. A suggested provision would be to provide a minimum of 1.83 meters from all major equipment surfaces and edges. Always allow proper space for the swing radius of the chamber doors including vehicular traffic.

NOTE

Do not scale drawings: If certain dimensions are required which are not shown on drawings, EWS should be contacted for the required dimension. EWS will not be responsible for any dimensional conflicts resulting from dimensions not shown on a

certified drawing. Do not use general sales literature or other general equipment submittals for construction, assembly and/or erection, unless so indicated.
Please note that some of the diagrams and/or photos in this MANUAL are conceptual in nature and may not be exact representations of the equipment purchased.

Preparation Prior to Assembly & Installation

Electrical & Fuel Availability

The electrical supply required is 600 VAC, 60 Hz, 3 phases. Connect power supply to Main Disconnect Panel (supplied by EWS) as per Supplied Electrical drawings in Section 4 of this manual.

DO NOT CONNECT THE EXTERNAL POWER SUPPLY TO THE EWS MOBILE INCINERATOR UNTIL ALL INTERNAL ELECTRICAL CONNECTIONS ARE COMPLETE AND THE SYSTEM IS COMPLETELY ASSEMBLED.

The fuel supply connections are located on the Secondary Chamber Container. Connect the flexible fuel supply lines to the fuel tank(s) located externally. There are fuel lines between the containers for fuel distribution which are to be connected before the external hook-ups and connections are made.

DO NOT CONNECT THE EXTERNAL FUEL SUPPLY TO THE EWS MOBILE INCINERATOR UNTIL ALL INTERNAL FUEL CONNECTIONS ARE COMPLETE AND THE SYSTEM IS COMPLETELY ASSEMBLED.

Assembly & Installation Overview

Specialized Tools and Equipment for Assembly and Installation

The complete assembly of the **EWS Mobile Incinerator** will require 2-3 full time qualified personnel for 2 days. The following list identifies the tools and equipment required to be supplied by the customer in order to proceed with the assembly:

- Crane
- Forklift
- Boom Lift, Scissor Lift and/or Scaffolding
- Steel Shims
- Ladder (12')
- Come-along
- Hydraulic Jack/pump
- Level
- Erection Wrench / Alignment bar

- Container Clamp 2”-Wrench
- Sling
- I-beam Clamp

The following list identifies the consumable items to proceed with the assembly:

- Anti-Seize Compound (Generic Graphite-Based Anti-Seize Compound)
- Gasket Spray-on Adhesive (Generic Spray-On Contact Cement)

Assembly Overview

The following general steps are the order in which the **EWS Mobile Incinerator** Package needs to be installed. Each step is detailed in the subsequent section.

ORDER OF ASSEMBLY (and detailed in following Section)

1) I-Beam & Spacer Base Structure (Base Frame Structure)
2) Connections Between Primary and Secondary Chamber Containers
3) T-Stack Section on Secondary Chamber Container
4) Internal Component Connections
5) Internal Connections
6) External Connections

NOTE

Important Notes to Consider Prior to and During Assembly

- Lifting lugs are provided on the stacks, and major accessories, and should be used in setting these units into position.
- Do not allow lifting chains or cables to put loads on piping, or mounting flanges as they may be damaged.
- Avoid dragging lifting gear across painted surfaces.
- When placing the system into position, be careful not to subject the refractory to mechanical shock, which may result in refractory damage.

Assembly Instructions

I-BEAM & SPACER BASE STRUCTURE (Base Frame Structure)

NOTE

For all fasteners used in assembly use regular-grade anti-seize spray to ensure that fasteners will be easily removed when disassembly is required.

NOTE

Do not fully torque bolts during initial assembly.

Correct Clamp Installation

When installing the clamps, install in such a manner that the installer pulls back on the wrench when tightening the clamp. From the installer's perspective, the smaller nut would then be located on the right of the large nut. If it is installed the other way, or during removal, a lift-truck or other lifting device will need to be employed for safety reasons.

Failure to follow the above instructions poses a safety hazard to an installer situated on top of the Primary Container as they would need to push forward to tighten or loosen the clamp.

ECO WASTE SOLUTIONS

CONNECTIONS BETWEEN PRIMARY AND SECONDARY CHAMBER CONTAINERS

ECO WASTE SOLUTIONS

Gasket adhesive spray being applied

Correctly Installed Gasket

NOTE

Once breech flanges are aligned and together bolt flanges together using the numerical order described in the pattern below.

Lifting Points
Container B (Secondary Chamber Container)
Move in this direction
Base Frame
Once in place, clamp Container B to Spacer
NOTE:
Place Container B about 0.5m (1-2ft) from spacer and move towards spacer until in place.

T-STACK SECTION AND SECONDARY CHAMBER CONTAINER

T-Stack and Stack Sections

NOTE

Each flange hole requires (1) bolt, (2) flat washers, (1) lock Washer and a Nut. Hard ware provided by EWS.

Install stack gaskets between stack sections.

Install refractory-lined *T-Stack Section* on top of the *Secondary Chamber* using the hardware provided. Then install the next three *Stack Sections* as per the drawing using hardware provided.

ECO WASTE SOLUTIONS

T-Stack and Stack Sections

This is a Sample Photo only of Erection of the Stack Sections

INTERNAL COMPONENT CONNECTIONS –

Flexible conduit in Container 2 (secondary chamber)

Feed flexible conduit from Secondary Container to Primary Container through utility duct into corresponding Junction boxes in Primary Container.

5 Junction Boxes located in Primary Chamber Container.

Connect each flexible conduit to the correspondent Junction Box (i.e. JB1 conduit with JB1 box) wire the terminal block inside the junction box following the labels on both the wires and the terminal block

DO NOT CONNECT THE ELECTRICAL UNLESS THE MAIN SUPPLY FROM THE SITE HAS BEEN INTERRUPTED AND THE INCINERATOR BREAKERS ARE IN THE OFF POSITION

Feed the 600v 60Hz power into the bottom of the Main Disconnect Panel. After the Main Disconnect Panel, Control panel and junctions boxes have been connected, the main supply from the site can be turned on now.

Switch on all incinerator breakers in the Breaker Panel

ECO WASTE SOLUTIONS

ECO WASTE SOLUTIONS

INTERNAL CONNECTIONS

Compressed air quick connect for Waste Oil Burner

Connect the air hose from the Waste oil Burner to the quick connect fitting

Feed wires for the tanks' level sensors and waste oil tank heater from the tanks through the opening beside the hose adaptors and connect to the junction boxes

Step 6: T-Stack and Stack Sections

Install stack gaskets between stack sections.

Install refractory-lined *T-Stack Section* on top of the *Secondary Chamber* using the hardware provided. Then install the next three *Stack Sections* as per the drawing using hardware provided.

T-Stack and Stack Sections

Propane Gas and Waste Oil Connections

<u>Reference</u>: Drawing ECOM2TNWO-GA-rB General Arrangement (GA)
Drawing ECOM2TNWO-P&ID

The Propane gas tank and evaporator are pre-assembled on a skid; the gas trains for the burners are pre-assembled to be installed in the building. The connection from the heavy ends trap in the tank skid to the building, including the low pressure regulator for the burners' gas train has to be carried on-site (by client's qualified contractors). There must be a proper clearance according to local regulations from the tank/evaporator skid to the containers. The complete propane installation has to be inspected and approved by the local authority (client's scope).

Propane Skid

The propane gas trains required more space than the space available inside the closed containers. To accommodate the extended propane gas train an extension room is formed using the open container doors in the Primary and Secondary chamber at eh burners' end. The roof, floor and end wall with a man door are supplied for assembly on-site

Propane Gas train extension room (Primary and Secondary containers)

Propane Burner, Waste Oil Burner and Gas Train Primary Chamber

ECO WASTE SOLUTIONS

Propane Burner Gas Train Secondary Chamber

Propane Burner Secondary Chamber

NOTE All Propane Gas connections to be done by a certified technician and should satisfy all local codes (all lines to be pressured tested), including the distance between the incinerator system and the tank.

Step 16: Electrical Connections
Reference: Electrical Drawings provided

NOTE All electrical connections, terminations and conduit installation to be done by a certified electrician and should satisfy all local codes.

Most of the internal wiring of the incinerator was completed at the factory and dismounted for shipping.

The wiring necessary on-site (by client's contactors) is:

- From the *power source* to the *Main Control Panel*
- From the incinerator's building to the propane vaporizer
- From the *Main Control Panel* to components Junction Box
- From the breaker box to the propane vaporizer
- From the *Main Control Panel* to the waste oil tank

Step 17: Start-Up

NOTE **CAUTION**: Do not attempt to place the equipment into operation until an EWS Service Technician has checked out all equipment and interlocks.

Upon completion of mechanical erection, interconnection of equipment and provisions of utilities as described above, arrangements should be made with the EWS field service department for scheduling of a service technician for initial start-up.

An EWS representative must perform start-up of all incinerator systems unless specifically arranged otherwise in writing by EWS.

Attempts to start-up incinerator systems by the buyer without prior written approval may result in revocation of all expressed or implied warranties.

Web: www.ecosolutions.com

Important Information

Proper operating and maintenance procedures must be followed in order for the ECO Model Incinerator system to perform at maximum efficiency.

Do not attempt to start or operate this equipment until this Operator Manual is read thoroughly and is understood.

The equipment has been designed with many safety features, however, like all thermal processes; this equipment is not free from the inherent hazards of high temperature processes.

Safety procedures and precautions must be followed at ALL times during operation.

There are safety procedures outlined in this Manual, however, no amount of written instruction can replace good judgment and safe operating practices.

Responsibility for the safe operation and maintenance of the equipment supplied rests solely on those operating it.

There are many engineered features incorporated into the ECO Model Incinerator system to free the operator of repetitive chores. They do not, however, relieve the operator of maintenance responsibilities. In order to maximize the operating life of the equipment, it is strongly recommended that the maintenance procedures, be followed diligently. It is advisable to keep an equipment log for recording maintenance activities along with unusual operation.

NOTE

In the event that the equipment is not operating in the normal manner, contact Eco Waste Solutions immediately at (905) 634-7022. It is important to report problems as soon as they are noticed to minimize damage that faulty operation could cause.

Design Specification Criteria

The **ECO M2TNWO** incinerator system was designed specifically for the **Brucejack** project under **Eco Waste Solutions (EWS)** proposal **PRB-ECO M2TN** presented on July 8, 2014 and based on information provided by Pretivm Resources Ltd.

The **Brucejack Project** is a gold mine located 65 km north of Stewart in northwestern, BC; the EWS team designed an incinerator with the following criteria in mind.

Waste Description

The solid waste material generated at this site is described as mainly camp and kitchen waste.

EWS assumed that the waste material is typical of mixed camp waste, non-hazardous solid waste consisting of food-waste, kitchen waste including packaging, cardboard, wood waste, and general refuse.

In addition, there will be some dewatered sewage treatment sludge. All of the solid waste materials will be available each day and will be processed as a mixture.

Important Notes

- Sewage sludge must be dewatered (equipment provided by others) to a minimum of 25-30% solid content prior to loading into the incinerator proposed herein
- Dewatered sewage sludge will be added onto a layer of other solid camp wastes and will comprise no more than 20% of the batch by weight. It will be loaded into the Primary chamber by utilizing a shovel (provided by others)
- Kitchen grease and kitchen oils should be in limited quantities (up to a 2 ½ gallon pail) per batch
- The solid waste, oil rags (if available), kitchen grease and dewatered sewage sludge will need to be co-mingled to ensure that any wet low heat value waste is mixed with the other drier materials
- Regardless of recycling programs that may or may not be in place at site, it is assumed that the solid camp waste will include some plastic packaging and containers. This waste is expected to be bagged or stored in skips/bins around the mine operation then brought to the incinerator by truck.
- Inappropriate materials including, but not limited to, reactive/explosive chemicals and items containing heavy metals will not be processed in the incinerator proposed herein.

Acceptable Waste-Streams

The **Eco Waste Solutions Waste Oxidizer** can process a range of waste materials. The following list has some of the potential waste streams that can be effectively processed in our system. This list is only a guide and should not be assumed to be an exhaustive list of materials. Please contact EWS for more details.

ECO WASTE SOLUTIONS

Acceptable Waste Materials Suitable for Processing in Eco Waste Solutions Technology

Solid Waste	Description	Origin
Food Waste	Food, food packaging and containers, plastic and paper waste from food preparation	Kitchen and dining areas
Domestic waste	General refuse such as paper, plastics, cans, bottles, cardboard, newsprint	Dormitory areas, recreation facilities, office areas, warehouse, plant and production facilities
Packaging	Cardboard boxes, paper, plastic containers, plastic film, Styrofoam, poly-weave bags	Inbound supplies to all work areas.
Wood waste	Skids, pallets, crates, including wood materials contaminated with chemical residues from Cyanide or explosives	Construction activity, inbound supplies, reagent and chemical packaging.
Absorbents	Rags, wipes, spill cleanup materials	From all work areas
Filters – Air and Fluid	Filters coated with fine particles and trapped solids, saturated with water or fluids (glycol, lube oils, fuel)	From water treatment facility, or generated at point of maintenance of vehicles, machinery and equipment
Medical Waste	Bandages, dressings, gloves, swabs, syringes, sharps	Medical clinic or first aid centre
Tires & Rubbers	Tires, belts, hoses	From vehicles and equipment maintenance shop
Waste Oil	**Description**	**Origin**
Used Oils	Used lubricating and hydraulic oils, including synthetics	From vehicles and equipment maintenance shop
Semi-solid Waste	**Description**	**Origin**
Sewage sludge	Dry filter cakes	From sewage treatment plant dewatering equipment
Kitchen grease, oils	Solid kitchen fats, grease, used cooking oil	Kitchen grease traps, fryers

1. Dewatered sewage sludge and kitchen grease can be comingled with waste – restrictions apply.

Unacceptable Waste-Streams

The following is a list of some of the waste-streams that should not be processed in the Eco Waste Oxidizer. This list is only a guide and should not be assumed to be an exhaustive list of materials. Please contact EWS for more details and to discuss your specific waste processing requirements.

A waste and procurement audit is highly recommended and encouraged to ensure that all sources of heavy metals are identified and diverted to other disposal methods. Small amounts of materials containing heavy metals may be acceptable if air pollution control equipment specially designed for metals removal is included with the package.

Unacceptable Waste Materials - NOT Suitable for Processing in Eco Waste Solutions Technology

Solid Waste	Description	Origin
Bulky Materials	Automotive or heavy equipment parts such as engine blocks and transmissions	From vehicles and equipment maintenance shop
Non-Combustible Materials	Drywall, asbestos, bricks, concrete, soils	Construction activity
Radioactive Materials	Smoke detectors, laboratory wastes	From Buildings, laboratories
Potentially Explosive Materials	Aerosol spray cans, large propane tanks, other pressurized vessels. Actual explosives	From warehouse, plant and production facilities
Heavy Metals	Items containing lead, mercury, cadmium, for example: batteries, electronic devices, fittings, old pipe work, fluorescent light bulbs, electrical switches, thermometers, PVC plastics, aluminum solder, photovoltaic cells	From maintenance activities, operations and construction activities
Liquid Waste	**Description**	**Origin**
High Alkaline or High Acid Materials	By-products of industrial processes, unrefined fuels	From warehouse, plant and production facilities

Waste Quantity

According to **Pretivm,** there will be three camps during construction and one during operation. For the two-year construction phase, the camps will house 550 people. Once in operation, the camp will decrease to 330 people for the anticipated 24+ years operation of the mine.

Pretivm provided EWS with a detailed list of waste materials (table below). Some of the waste material has been deemed unacceptable and are highlighted in red font, but the majority of the waste streams are acceptable and will be processed accordingly in the incinerator.

ECO WASTE SOLUTIONS

Catalog	Material	Quantity			
		Supply		Waste

	Sludge from Water Treatment Pla		t/yr	1500-3000?	t/yr TBD

It is important to note that the waste materials and corresponding volumes (as seen in the table) is based on a population of 330 people only (not 550, which is the higher population, during the construction phase). Pretivm advises us that they were only able to provide us with a **partial list**, of waste materials, at this time.

Based on the table, EWS performed calculations to determine the total volume of acceptable solid waste generated at the camps, including their waste characteristics (total moisture content, average waste density and average heat value). See table 1 below:

Table 1: EWS Calculations of Waste Volume & Waste Characteristics

Solid waste Mixed With Sewage Sludege												
Waste Category	% of Total MSW Stream	kg/year	Condition	As-Received Heat Value,HHV	Heat Value Percentage,HHV	H_2O content		Ash Content		Bulk Density	Specific Volume

Sewage Sludge	4.6%	*15000*	*Semi-Solid*	*1000*	*46*	*80%*	*3.68%*	*10%*	*0.46%*	*50.00*	*0.020*	0.00
TOTAL	***100.0%***	***326320.00***	***Solid***	***5651***		***35.0%***		***7.3%***		***12.369***	***0.081***	

To summarize the table above, EWS has prepared this table below:

Table 2: Summary of EWS Calculations of Waste Assumptions

Waste Description	Annual Waste Volume Generated	Daily Waste Volume Generated	Total Moisture Content	Average Waste Density	Average Heat Value
Mixed Solid Camp Waste Material	~330,000 kg	~894 kg	Up to 35%	12 lbs/ft^3	5600 BTU/lb

Based on the table, EWS performed calculations to determine the total volume of acceptable waste oils generated at the camps, including their waste characteristics (total moisture content and average heat value). See table 1 below:

Table 3: EWS Calculations of Waste Oils

Catalog	Material	Waste Quantity	Unit
Fluids/Oils/Fuels	Lubricants	830	L/yr
	Engine Oils	12000	L/yr
	Waste Hydr Oil	14400	L/yr
	Waste Trans Fluid	240	L/yr
	Brake Oil	24000	L/yr
	Axel Oil	8800	L/yr
	Total	60270	L/yr
	Flow Rate Daily	231	L/Day @ 5 days/week
	Flow Rate Hourly	38	L/Hr @ 6 hr/day
		10	GPH
	Assuming HHV	125000	Btu/Gallon
	Heat Output	1271023	Btu/Hr
	Air Capacity	12710	SCFH

To summarize the table above, EWS has prepared this table below:

Table 4: Summary of EWS Calculations

Waste Description	Annual Waste Oil Volume Generated	Daily Waste Oil Volume Generated	Total Moisture Content	Average Waste Density	Average Heat Value
Waste Oils	~60,270 L	~231 L	Up to 5%	n/a	12,5000 BTU/lb

However, as Pretivm indicated that this list was based on only 330 people and not 550 and that it was only a **partial list** of waste materials generated at the mining camps, EWS resorts to past experience working with mining clients in remote locations to determine the appropriate sizing of the incinerator package for the **Brucejack Project.**

To calculate the **solid waste generation** daily rate at any given mine site, EWS typically uses a per capita waste generation rate or “rule of thumb” of 2 kg per person per day.

Also, EWS uses an industry standard per capita waste generation rate of 0.75 kg to calculate the amount of **dewatered sewage sludge** produced on any given day at the mine site.

Please see table below for more information:

Table 5: EWS Per Capita Waste Generation Rates

Waste Material Description	Per Capita Waste Generation Rate
Mixed Solid Camp Waste	2.0 kg
Dewatered Sewage Sludge	0.75 kg
Total Mixed Waste Material Per Capita Waste Generation Rate	**2.75 kg**

It is assumed that the **waste oils** generated will not be affected by the size of the camp population and therefore believe that the waste oils generated at the mine site will remain the same as calculated in **Table 3: EWS Calculations of Waste Oils** and summarized in **Table 4: Summary of EWS Calculations.**

Therefore, based on this rule of thumb for solid waste, EWS calculates that approximately **1513 kg** of solid mixed waste material will be generated per day during the construction phase and up to **908 kg** per day during the operation phase. Please see table below for EWS calculations:

Table 6: EWS Calculated Daily Waste Generation by Project Phase

Project Phase	Population	Total Per Capita Waste Generation Rate	Total Daily Waste Generation Rate
Construction Phase	550	2.75 kg	1513 kg/day
Operation Phase	330	2.75 kg	908 kg/day

EWS Waste Assumptions

To compare, based on EWS past experience working with remote mine sites, the table below summarizes EWS typical waste assumptions which is very similar to the waste characteristics calculated in **Table 2: Summary of EWS Calculations of Waste Assumptions.**

Table 7: EWS Waste Characteristic Assumptions

Description	Total Moisture Content	Average Waste Density Range	Average Heat Value
Mixed Solid Camp Waste Material	Up to 45%	10-15 lbs/ft^3 160-240 kg/m^3	5000 BTU/lb 11655 KJ/kg

Addressing Waste Oil

To address the need of disposing waste oils generated at site, the ECO M2TNWO has two (2) **Waste Oil Burner (WOB) Packages**

These WOBs can dispose of the acceptable waste oils available on site and function as a fuel source to operate the incinerator system, in lieu of propane. This packaged burner will not only dispose of the waste oils in an environmentally sound manner, but it will also decrease the daily operating costs of the waste incinerator system.

To address the need of disposing any waste oils generated at site a **Waste Oil Burner (WOB) Package,** has been integrated as part of the incinerator system to dispose of up to 20 L/hr of waste oil

Waste Oil Specifications

•Each Waste Oil burner is designed to burn up to 10 L/hr of the following fuels:

Used crankcase oil up to 50 SAE
Used transmission fluid
Used hydraulic oils
#2 fuel oil
#4 fuel oil
#5 fuel oil

NOTE: Used oils may contain other substances, including gasoline, which may hinder performance.

• Hazardous wastes, such as chlorinated solvents, are NOT to be mixed with your used oil

NOTE

This incinerator was only designed for the type of waste and amount of waste mentioned above. It is important that the waste quantities and characteristics described above are processed in the incinerator. Otherwise, the incinerator system will not operate properly.

General Operating Overview

The operation of the **ECO M2TN WO Waste Incinerator** follows 7 general steps that take place over a 12-hour period.

Although all 7 steps are critical in the general operation of the incinerator system, this section of the manual focuses on **Step 1, Step 3** and **Step 4** and how to start the system and monitor it during operation.

This section will also cover **Step 7** on how to use the historical charts, store incinerator data, and access incinerator historical information for record keeping purposes.

Monitoring and Data Acquisition System

Overview

The **PLC** automatically monitors the entire process and some system inputs are recorded and logged for record-keeping purposes and also allows for historical trending of key operating conditions.

The integrated **PLC** in the Main Control Panel monitors and records the following:

1. Temperature sensors
2. Differential pressure sensors with transmitter (draft)
3. Monitoring of burner faults
4. Fan amperage monitoring via current transducer and VFD
5. Door position interlock monitoring
6. High temperature limit and interlock
7. Damper positions

All data can be transferred to storage by using the USB flash memory installed in the back of the HMI

Data Logging

Data from the Incinerator is logged automatically on the HMI and will need to be manually retrieved from the HMI.

Using Historical Charts

Accessing Historical Information

a. It is recommended that a dedicated folder be set on the destination computer that is used for storing data from the Incinerator Package (e.g. “Incinerator Data”)

b. Copy the data file “**RSView Enterprise Viewer.EXE”** from the USB Flash Memory (extracted from the back of HMI, in the panel) to this dedicated directory. Only has to be done the first time

c. Copy and rename the text file with the date to easily access previous week’s information.

d. To open data, double click on the RSView Enterprise Viewer application. From the File menu select Open. Make sure you are searching in the folder containing the historical data files.

e. In the Open dialogue box, in the File Name type **“ *.* ”** to view all files. Click on the specific Text Document that you wish to open.

f. Once the data is open, it will look similar to the following:

RSView Enterprise File Viewer - [List View - Nato_History (11-April-10)]

Ready

Saving Data to Excel

a. To save the data in a Microsoft Excel format – with the data open (as above) from the File menu select Save As and select the directory where you wish to save the file. Make sure you have a logical name in the File Name field (it will default to the same file name as the TXT file you have opened). Make sure CSV is selected in the "Save as Type" drop down box and select the Save button.

b. To view the file in Microsoft Excel, open the Excel application and from the File menu, select Open and then make sure that "Files of Type" is on "Text Files"

c. Choose the file you wish to open and select "Open" from the dialogue box. The file is now open in Excel.

HMI Operator Interface

Main Control Panel Components

Number	Name	Purpose
1	**Main Disconnect Switch**	Isolates the incinerator from its source of electric power.
2	**HMI Operator Interface**	Displays various screens reflecting system performance.
3	**Control Power ON**	1. Green light indicates the control power in the panel is on. 2. Pushing it if the **Emergency-Stop** is out will turn on the control power.
4	**Emergency Stop Pushbutton**	Stops the cycle if it is on and disables any possibility of starting it.
5	**Programming Port**	Allows access to PLC and HMI

The HMI Operator Interface

The **HMI Operator Interface** controls the operation of the incinerator directly from the **Main Control Panel.**

The **Main Menu** screen displays all the available options for viewing the system in operation.

The **HMI** has a touch-screen and items can be selected by touching them on the screen.

Main Menu

The first screen the operator will view is the **Main Menu** (see below).

Front View

When the ***Top View*** button is selected, an overview of the incinerator and related components is displayed. This shows key temperatures, flows, and other indicators of what is happening in the process in a real-time basis.

NOTE

The system will not start if there are alarms or faults present.

At any time, touch **Main Menu** to go back to the main screen.

Primary and Secondary Status

When the ***Primary Status*** **or Secondary Status** button is selected from the **Main Menu,** a screen will display the status of all the operating parameters of the Primary Chamber or Secondary Chamber accordingly, such as the temperatures and the time remaining in the cycle, as well as displaying other informational items such as status of the door and blowers, etc.

On the Primary Status screen, the operator can change the burn time of the cycle by selecting “BURN TIME” and entering a time (in minutes), to either prolong the burn time, or decrease the burn time depending on the waste mixture; for example a very wet batch of garbage will take more time to burn than a dryer waste.

In this Primary Status screen the burning of waste oil can be selected and where system is started

At any time, touch **Main Menu** to go back to the main screen.

Primary Status

Secondary Status

Alarm History

When the ***Alarm History*** button is selected a screen will display the last 128 faults with the date & time of occurrence.

The operator can press the *CLEAR ALARM HISTORY* to clear all of the faults, if they wish to. This does not affect the record-keeping feature of the system.

At any time, touch **Main Menu** to go back to the main screen.

Overview of Historical Charts

The **HMI** operator interface monitors and records (every minute) critical operating parameters of the incinerator system like the temperature, motors, draft, load weights and alarms. Each operating parameter has its own graphic display for the operator to view, at any given time. Each display can easily be selected from the **Main Menu** of the **HMI**. The display will show the specific data collected from previous burn cycles.

This **Incinerator Data** is important for regulatory purposes and for general operating purposes.

Temperature History

For example, when the ***Temperature History*** button is selected, the screen will display the trend in temperature during the operation of the system, include date & time of occurrence of that specific temperature.

Motor Currents History

When the ***Motor Currents History*** is selected a screen will display the motor currents from the Primary Burner and the Secondary Burner, in AMPS, during the operation of the system, including date & time of occurrence of that specific motor current.

Draft History

When the ***Draft History*** button is selected a screen will display the draft during the operation of the system, include date & time of occurrence of that specific draft trend.

Standard Daily Operating Procedures

Daily Circular Inspection

1. Check that all valves leading to the burners are open
2. Check that the slide gates on the blowers are open
3. Check waste oil valves from tank to burner are open and lines leak free
4. Check that all circuit breakers are in the “ON” position
    - In the main breaker panel
    - For the propane skid, check the circuit breaker in the primary container to ensure the vaporizer has power. The vaporizer should feel warm to the touch
5. Fix any items found incorrect.

Incinerator Daily Start up

1. Ensure that manual slide gates for each blower are in the open position for free airflow into the **Primary and Secondary Chambers**

1. Primary Chamber blower Manual Slide Gate Open Position
2. Primary Chamber blower Manual Slide Gate Closed Position
3. Secondary Chamber blower Manual Slide Gate Open

2. If propane odour is noticed, visually inspect the burner piping to ensure that there are no gas leaks.
3. Ensure the draft gauge connection is tight and sealed. This is tubing located in the back of the **Primary Chamber.**

Draft Gauge Hose connection

4. Unlatch clamps on the **Primary Chamber** door, open and secure in the open position

5. Ensure the Primary Chamber floor is cool (less than 50°C). Remove all the ash from the previous burn and store ash in ash bins.

If the floor is hotter than this temperature the waste may spontaneously catch on fire during loading.

6. Tips for loading. The following loading procedure will decrease burn time and allow for more uniform burn.
   a. Load the less dense waste first
   b. Load dry waste first. Placing wet waste near the top of the Primary Chamber allows moisture to evaporate early in the cycle.

c. Place waste on the weigh scale, once the waste is on the weigh scale the Operator has to push the RECORD WEIGHT (black button) on the Weigh Scale Push-Button Station. By pressing this button, the weight value of that particular load of waste is sent to the PLC and the weight is recorded. At this time, the MAXIMUM WEIGHT (green button) will flash green once to show that the weight has been logged.

d. Then, the operator must take the waste and load it into the Primary Chamber.

e. The operator returns to the weigh scale with some more waste and repeats Steps c and d. This entire procedure is repeated until the maximum load weight for the Primary Chamber is reached. The PLC will indicate this to the operator when the MAXIMUM WEIGHT (green light) comes on and remains on. This indicates that the maximum weight permitted, in this case, the incinerator is designed for a maximum of 2,000 kg of waste material.

f. The Primary Chambers are loaded, and the incinerator is ready to start.

NOTE

No more waste should be loaded into the Primary Chamber after the load has reached the maximum weight, or in the case of lower density waste, the chamber is ¾ full (the burner requires open space in front of it to allow for a proper flame)

NOTE

Do not throw the waste towards the sides of the Primary Chamber. Doing so will damage the ceramic fiber refractory.

NOTE

Load only the waste stream that the system has been designed for. DO NOT load a lot of high BTU rated waste for one burn (i.e. do not load three (3) 5 gallon pails of bacon grease or wood only). Doing so will result in excessive temperatures in the system reducing the life of the refractory.

NOTE

Do not load the Primary Chamber above its rated capacity by weight or above the burner opening.

7. Lock the **Primary Chamber** Door and ensure all latches are properly engaged.
8. Proceed to the **Main Control Panel.**

NOTE

The burn time will be set to the previous burn, if you wish to change the set time, proceed to the System Status screen and click on the BURN TIME button. The minimum number of minutes you can enter is 180 (3 hours). When you have finished, the time will be displayed in minutes beside the BURN TIME button

NOTE

The burn time value (in minutes) determines the length of the burn cycle before cool down cycle starts.

9. Check that the primary door shows closed on the **HMI SYSTEM STATUS** screen or the **HMI PRIMARY STATUS** screen**.**

   Check that no alarms are displayed. The **HMI** will display any faults, which need to be cleared before the system can start.

10. Check that the EMERGENCY STOP BUTTON is out.

11. Check that the **green control light is illuminated.**

    Do not use this incinerator to burn waste oil only. Always burn a complete load of solid waste when burning waste oil

12. On the **HMI** Primary Status Screen make sure to select the proper combination of Solid Waste, plus any combination of: no Waste Oil, Primary and and/or Secondary Waste Oil.

    a. Waste Oil System Off: Ensure the Waste Oil burners are pulled out and the Limit switches are made. The HMI Primary Status will show burners are out. ***Make sure to put the PLUGS into the opening of the waste oil burner in each chamber***.

Waste oil all the way out limit switch made

Chamber plug being installed

Waste oil burner secured with pin

b. WASTE OIL SYSTEM ON: Ensure the plug is removed from opening from the chamber or chambers where waste oil is going to be used, and push the Waste Oil Burner all the way in, making contact with the Limit Switch in, the HMI Primary Status will show which burner is in. Primary, Secondary or both

Remove plug

Push all the way in until front limit switch is made

13. On the **HMI** Primary Status Screen press the “START SYSTEM” button. The following steps will automatically take place, controlled by the **Main Control Panel**:

    a. Waste Oils System Off

        I. The **Primary Blower and Secondary Blower** will purge the system for 2 minutes.

        II. The **Secondary Burner** will purge for safety, and upon completion will ignite.

        III. Once the **Secondary Chamber** temperature reaches 1000°C, the **Primary Burner** will purge for safety and upon completion will ignite.

IV. The burn time will start counting down when the temperature in the **Primary Chambers** reaches 427°C.

b. Waste Oil System On

I. The **Primary Blower and Secondary Blower** will purge the system for 2 minutes.

II. The **Secondary Burner** and **Waste Oil Burner** will purge for safety, and upon completion they will ignite.

III. Once the **Secondary Chamber** temperature reaches 1000°C, the **Primary Burner** on will purge for safety and upon completion will ignite.

IV. The burn time will start counting down when the temperature in the **Primary Chambers** reaches 427°C.

NOTE The Main Control System will maintain proper operating conditions for the ECO M2TN WO.

14. During the system start-up, it is recommended to monitor its operation. The barometric damper on the T-stack helps control the draft through the system, recommended draft is between 20-30 Pa (displayed in Top View and Primary Status screens). Draft readings above 30 Pa result in gases traveling at high speed inside the system; reduce the draft by opening the damper (using the chain attached to the damper). Ensuring the draft stays within the recommended values, will maintain the system running an efficient burn, proper fuel consumption, clean emissions, etc.

After the burn cycle is completed the system will enter the cool-down cycle and the following things will occur:

- Primary Chamber & Secondary Chamber burners OFF
- Secondary Chamber Blower OFF
- Primary Modutrol 100% open
- Primary Blower ON

Once fully cooled and the temperature is below 50°C, proceed to the **Primary Chamber Clean Out Procedures**

Primary Chamber Clean Out Procedures

Operators responsible for loading and cleaning out incinerators should wear appropriate protective equipment, including eye protection, dust masks, heavy gloves and safety shoes with puncture-proof toes and soles to avoid injury.

Although the ash from the system is considered sterile and will not contain microorganisms, it may contain a quantity of sharp objects, such as broken glass and other sharps which may not be fully destroyed in the burning process, and may thus still pose a hazard to persons who clean out the ash and residues. Also removing the ash does create dust particles in the air. Dust should not be inhaled. The operator must wear dust protection safety gear.

Please follow these steps when the cycle is complete:

1. When the internal temperature of the **Primary Chamber** has cooled to less than 50°C, lock out the power to the system on the **Main Control Panel** by moving the main disconnect to the “OFF” position.
2. Unlock all door latches on the access door to the **Primary Chamber.**

3. While standing in front of the **Primary Chamber** door, slowly open the door to allow clear entry. Secure **Primary Chamber** Door in the OPEN position.
4. Clean the **Primary Chamber** by using ash handling tool(s) and proper safety equipment (not provided).
5. Inspect the interior of the **Primary Chamber** for wear and inspect around the door seals to ensure the door will maintain a tight seal upon closure.
6. Check the air inlet holes and remove any obstructions if necessary.
7. Inspect the door seals to ensure there are no gaps between the door gasket and the door jamb.
8. Close the **Primary Chamber** access door by clamping each latch until it is tight.
9. Clean the inspection **View Port** (glass) with a mild soap and water. To clean the view port, unscrew it by hand and re-tighten by hand.

In Case of Emergency

1. Go to manual Slide Gates on the **Primary Chamber**, located just after the blower and close them all the way. This will help to put the fire out in the **Primary Chamber** out.
2. Check alarms to see what the problem is.
3. Do not open the door of the **Primary Chamber** unless the temperature inside the chamber is below 50°C.
4. Call a certified technician to fix the problem and/or consult with **Eco Waste Solutions Customer Service Department at 905.634.7022, toll free 1-866-326-2876.**

Start Up After Power Failure

1. Once the power is restored turn breaker (main disconnect) back on.
2. The Operator Interface and PLC will begin a boot up procedure. Wait until the **HMI** on the **Main Control Panel** has booted up before turning the control power to the panel back on by pressing the Control Power ON button.
3. When the power is restored to the **Main Control Panel**, the button should illuminate.
4. If the system was interrupted during a burn cycle, on the **HMI SYSTEM STATUS** screen press the "**START BURN**" button to restart the system. If the system was interrupted during cool-down cycle, it will resume the cycle where it left off.
5. Ensure the propane vaporizer circuit breaker is "ON" and check if any of the propane pressure switches require reset at the burner valve train and at the top of the vaporizer.

Dealing with Warning and Faults

Troubleshooting

The burn cycle will not start if one of the following conditions exists:

1. The system still is in “cool-down” cycle. Wait until the “cool down” cycle is complete.
2. There is a fault in the system as indicated on the **HMI**.
3. Loss of power due to any one or more of the following:

- The main disconnect (see image) is off or there is no electrical power. Turn on the disconnect switch or check why there is no power.

Power is OFF in this position

Power is ON in this position

- An open circuit breaker or blown fuse. Check the breakers and fuses, replace any that are defective.

- The EMERGENCY STOP is pushed in. Twist the EMERGENCY STOP button to unlock, and then push the CONTROL POWER ON button. The CONTROL POWER BUTTON should now be illuminated green.

4. If on the Main Control Panel HMI the **Primary Chamber** door is not closed, the door has not been shut properly. Adjust the limit switch lever arm if necessary. Check the limit switch and that the wiring is in working order.

5. If fuel pressure is low, system will not start. This is an indication the vaporizer is not “ON”

6. If fuel pressure is high, the pressure switches will trip. The pressure switched will have to be reset and if they trip again the propane regulators will have to be checked.

PLC Processor Problem

- Check the run light on the PLC processor. If it is on the PLC it is ready.
- “OK LIGHT” is green = Controller is OK.
- “OK LIGHT” is Red Flashing = this is a recoverable fault, check the PLC processor. This fault is very unlikely to occur.
- OK LIGHT is Red = this is a non-recoverable controller fault. Cycle Power. The OK LED should change to flashing red. If LED remains solid red, replace the PLC. This fault is very unlikely to occur.
- DCHO light is green = this indicates the PLC processor has lost the program. The PLC is equipped with a flash card that will automatically load the program back onto the PLC.

ECO WASTE SOLUTIONS

Possible Problems, Causes and Solutions

Problem	Causes	Solutions
Blower Fails to start	Over load tripped, blown fuse	Turn power off. Open Panel and reset overload. Check fuse and replace.
	Motor starters or contactor coil is burnt out	Locate contactor for Blower and visually observe if the contactor is pulled in. Use a volt meter to check for voltage across the coil If there is voltage across the coil and the contactor is not pulled in, replace the contactor.
Secondary Burner won't ignite	Bad Electrodes	Refer to Maintenance Section of this manual.
	Fuel Pressure fault	Ensure there is enough fuel in the tank Reset pressure switches on burner fuel train Reset vaporizer switch (on top of vaporizer) Ensure vaporizer is turned ON
	Fuel Line Leak	If propane odor is noticed, close all valves, tighten any fittings or replace leaking piping.
	Door Switch not making contact	Make sure main door is closed and latched shut. Make sure limit switch is hitting striker plate.
	Burner main switch is turned off	Turn switch on.
	Burner alarm has been tripped	Acknowledge burn alarm and then hit the reset button on control panel.
	Bad Thermocouple	Replace thermocouple.
Primary Burner won't ignite	Bad Electrode	Refer to Maintenance Section of this manual.
	Fuel Pressure Fault	Ensure there is enough fuel in the tank Reset pressure switches on burner fuel train
	Fuel Line Leak	If propane odor is noticed, close all valves, tighten any fittings or replace leaking piping.

Problem	Causes	Solutions
	Door Switch not making contact or broken	Make sure main door is closed and latched shut. Make sure limit switch is hitting striker plate.
	Secondary temperature not at 1000°C	Wait until Secondary temperature is at 1000°C and try again.
	Burner main switch is turned off	Turn switch on.
	Burner alarm has been tripped	Acknowledge burn alarm and then hit the reset button on control panel.
Persistent Black Smoke	Insufficient air supply to Secondary Chamber to completely consume emissions	Check to ensure combustion air blower/damper assembly is operating properly.
	Secondary Chamber is not hot enough.	Check that the Secondary temperature is operating at required temperature set point.
	Secondary Chamber is not hot enough.	Too much draft, open barometric damper.
	Overloading or loading highly volatile material	Decrease load size on next batch (confirm by weighing), ensure the waste mix is correct.
	Burner failure	Check burner operation – if no flame or a poor flame is visible through the flame view port adjust air/fuel ratio.
	Operation at too high a Primary Chamber temperature	Check/decrease primary chamber combustion air.
Smoke coming out of Primary	Too much air	Check dampers on primary blower.
	Too much volatile material loaded	Decrease load size on next batch to ensure the waste mix is correct.
	Low draft	Close the barometric damper in the t-stack section
	Primary Chamber temperature too high	Waste loaded may not be a good mix of heat value .
Too much fuel usage	Too much secondary combustion air	Check/reduce secondary combustion air.
	Too much air infiltration	Reduce air flow by adjusting the damper.
	Fuel leakage	Check fuel trains and burners for fuel leakage.

Problem	Causes	Solutions
	Wet waste	Spread wet waste with other waste through several loads – do not charge all of the wet waste at one time.
	Excessive draft	Check/reduce draft – check door seals and other seals for leakage adjust damper.
	Burner setting too high	Check air/fuel mix.
Incomplete burnout/poor ash quality	Build-up around air holes – clogged with ash from previous burn	Check around air holes and clean.
	Poor draft	Draft should be -0.25-0.06 KPa (or 1.0-0.25"W.C).
	Too much wet waste – overloading system	Spread wet waste with other waste through several loads – do not charge all of the wet waste at one time.
	Insufficient burn time	Allow longer burn time period.
Waste Oil Burner		
System will not start when Solid is selected	Waste Oil burner is inserted into the Secondary Chamber	Remove Waste Oil burner assembly from the Secondary Chamber. And place the plug into the port
System will not start when Solid and Waste Oil are selected	Waste Oil burner is not inserted into the Secondary Chamber	Remove the plug from the port and insert the Waste Oil burner assembly into the Secondary Chamber.

Possible Alarms (Faults)

#	ALARM (System Fault)	SOLUTION
1	The Primary Chamber Thermocouple is faulted	See corrective maintenance procedures. Section 7 on this manual
2	The Secondary Chamber thermocouple is faulted	See corrective maintenance procedures. Section 7 on this manual
3	The Secondary Stack Thermocouple is faulted	See corrective maintenance procedures. Section 7 on this manual

#	ALARM (System Fault)	SOLUTION
4	The primary burner is faulted	The primary burner has failed to light when it received a signal telling it to start. To reset the burner, press the reset button located on the Burner. Ensure the vaporizer is ON, the pressure switches are not tripped and all valves from tank to burner are open If this does not start the burner, refer to Supplier Catalogue (Riello Burner) Section 8 of this manual.
5	The secondary burner is faulted	The secondary burner has failed to light when it received a signal telling it to start. To reset the burner, press the reset button located on the Burner. Ensure the vaporizer is ON, the pressure switches are not tripped and all valves from tank to burner are open If this does not start the burner refer to Supplier Catalogue (Riello Burner) Section 8 of this manual.
6	The system has shut down due to primary blower low air flow. 	Visually examine the primary blower for any obstructions that may be causing low air flow. Check slide gate located between Primary chamber and blower, ensure it is open. Check damper assembly, ensuring modutrol crank arm is still connected and that butterfly damper is open, allowing air flow. Air proving switch may be defective. Refer to Section 6 of this manual. There are two ports on the air flow switch marked V and P. Ensure the inlet tube is attached to the port marked “P” for pressure. V stands for vacuum. Ensure the “V” port is open to atmosphere and is not blocked. If no air restriction is observed (i.e. blockage in the tube) change the air proving switch. Refer to Section 7 of this manual.

#	ALARM (System Fault)	SOLUTION
7	The primary blower motor overload is tripped.	Turn power off on Control panel by turning the Main Disconnect to the OFF position. Reset overload.
8	The system has shut down due to secondary blower low air flow. 	Visually examine the Secondary Blower for any obstructions that may be causing low air flow. . Check slide gate located between Secondary chamber and blower, ensure it is open. Check damper assembly, ensuring Modutrol crank arm is still connected and that butterfly damper is open, allowing air flow. Air flow switch may be defective. Refer to Section 6 of this manual. There are two ports on the air flow switch marked V and P. Ensure the inlet tube is attached to the port marked “P” for pressure. V stands for vacuum. Ensure the “V” port is open to atmosphere and is not blocked. If no air restriction is observed (i.e. blockage in the tube) change the air proving switch. Refer to Section 7 of this manual.
9	The Secondary blower variable frequency drive is faulted.	Push fault reset button on the HMI If fault persist check the error code on the variable frequency drive and check manual for troubleshooting alarm.
10	The Waste oil tank is low	This is a warning which will appear for 5 seconds if you try and start the system when solid and waste oil is selected, the system will not start. Add waste oil to the tank and the alarm should reset itself.
11	The Waste oil burner is not all the way in.	Check that the burner is all the way in. Check the limit switch arm and wiring.
12	The Waste Oil burner is not all the way out.	Check that the burner is all the way out and connecting with the limit switch. Check the limit switch arm and wiring.

ECO WASTE SOLUTIONS

MAINTENANCE INSTRUCTIONS

SUMMARY OF PREVENTIVE MAINTENANCE INSTRUCTIONS

IF APPLICABLE: The air compressor pump is shipped with break-in oil which should be changed after the first 8 hours of operation.

Daily Maintenance

Freq.	Routine	Component	Description
Daily	Inspection & Cleaning	Burners	Inspect fuel lines for leaks.
Daily	Inspection & Cleaning	Refractory	Check inside the Chambers for shrinkage or any exposed metal.

Weekly Maintenance

Routine	Component	Description
Inspection & Cleaning	Blowers and Assembly	Modutrol crank arm connected to damper.
Inspection & Cleaning	Blowers and Assembly	Slide gates are open.
Inspection & Cleaning	Burners	Secondary Burner maintenence
Inspection & Cleaning	Waste Oil Burner Filter	Clean the canister filter
Inspection & Cleaning	Air compressor	Check air filter
Inspection & Cleaning	Air compressor	Pull ring on safety valve and allow the ring to snap back to normal position (Check for free operation of the safety valve)
Inspection & Cleaning	Thermocouples	Remove and clean thermocouples as necessary – inspect for damage. Replace if necessary.

Monthly Maintenance

Routine	Component	Description
Inspection & Cleaning	Blowers and Assembly	Check the fan wheel for any wear or corrosion, as either can cause catastrophic failures
Inspection & Cleaning	Refractory	Check the refractory in the Secondary Chamber for shrinkage, anything greater than 1.2cm should be patched (i.e. gaps between modules exposing metal surface)
Inspection & Cleaning	Waste Oil	Visually check all electrical components
Inspection & Cleaning	Waste Oil	Remove heater element from casing and inspect for build-up. Clean any deposits. When reinstalling the heater element always ensure the bundle will be restarted immersed. **NEVER** use the inline oil heater dry
Inspection & Cleaning	Air compressor	Check all fasteners for proper tightness.

Quarterly Maintenance

Routine	Component	Description
Inspection & Cleaning	Refractory	Inspect door gasket for damage or heat damage. Replace segments, if necessary. Doors must close tightly and securely.
Inspection & Cleaning	Refractory	Check all refractory for damage. Patch or replace as needed. Patch if modules show a little gap and replace modules if the modules have shrunk excessively (greater than 1”)
Inspection & Cleaning	Paint	Maintain paint exterior to protect metal from heat damage

Yearly Maintenance

Routine	Component	Description
Detailed Maintenance	Refractory	Replace door gasket
Inspection & Cleaning	Electrical	Check the limit switch

24 to 60 Months

.

Periodicity	Routine	Component	Description
24 Monthly	Detailed Maintenance	Refractory	Replace the door sills on Primary Chamber
24 Monthly	Detailed Maintenance	Refractory	Replace the door sills on Secondary Chamber
60 monthly	Detailed Maintenance	Refractory	Relining of Secondary Chamber.
60 monthly	Detailed Maintenance	Refractory	First stack section to be relined.
60 monthly	Detailed Maintenance	Fuel Tanks	Inspect Fuel tanks

PREVENTIVE MAINTENANCE INSTRUCTIONS

Instruction Classification

Each component is associated with an identification number, see table below:

System Component	Identification number
Primary Blower	01-001
Secondary Blower	02-001
Primary Burner	01-002
Secondary Burner	02-002
Refractory	05-001
Waste Oil Burner	02-003
Air Compressor	03-001
Main Control Panel	03-010
Paint	05-003
Electrical	05-004
Limit Switch	05-005

To differentiate if the instruction is weekly, monthly, quarterly or yearly, the above identification number will be followed by a letter:

Daily: D
Weekly: W
Monthly: M
Quarterly: Q
Yearly: Y

For example**, 01-001.Q.01** Primary blower assembly quarterly instruction number 1.

ECO WASTE SOLUTIONS

Zero Mechanical State & Lock Out Instructions

Proper maintenance of the equipment is essential to ensure long term, reliable operation of the EWS model Incinerator. The preventive maintenance instructions are outlined in this section of the Facility Manual.

NOTE
The warranty will become void if proper maintenance is not performed as instructed.

Safety

During maintenance of the EWS mobile incinerator, it is very important to be aware of special hazards. Two safety programs are described in the following sections:

1. Zero Mechanical State
2. Power Lock Out Instructions

Failure to comply with these instructions during maintenance could result in injury or death. The responsibility for implementation of a comprehensive safety program rests with the operating staff and supervision. The safety instructions in this Facility Manual should be considered only as a starting point for the safety program at site.

ACCIDENTS CAN BE PREVENTED
A CAREFUL WORKER IS THE BEST SAFETY DEVICE

Zero Mechanical State

Zero Mechanical State (ZMS) exists when the possibility of an unexpected mechanical movement has been eliminated. During maintenance, it is mandatory to totally deactivate the incinerator so that there is no possibility of an unexpected machine movement. Power lock-out, described in the next section, is commonly used for this purpose. Most machines are powered by electrical, hydraulic or pneumatic drives. Energy may be stored in a shutdown machine in various ways: Air pressure in a cylinder, hydraulic fluid stored in pressurized hoses, or machine members whose weight can generate fluid pressure. Therefore, just cutting off the electrical power may not be enough to neutralize all power sources. Certain maintenance instructions at site should require ZMS condition as a matter of course.

Zero Mechanical State (ZMS) Checklist

1. Every electrical power source to the incinerator must be cut off and locked out (to prevent others who may not be aware of maintenance work from turning the power back on inadvertently).
2. Ensure that the mechanical potential energy of the incinerator is at its lowest practical value so that opening of pipe, tubing, hose or actuation of any valve will not produce an unexpected movement that could cause injury.

3. Check that there is no pressurized fluid (air, oil, gas or other) trapped in the incinerator lines, cylinders or other components. This will ensure that there will be no incinerator motion when a valve is actuated.

4. Secure loose or freely moving parts so that there is no possibility of accidental movement.

Power Lock Out Instructions

Unexpected operation of electrical equipment started by automatic or manual remote control may cause injuries to persons who happen to be nearby. For this reason, when repair work is to be done on motors or other electrical equipment the circuit should be opened at the switch box and the switch pad locked in the OFF position. Tag the switch with a lock out tag indicating who must be contacted before the power is turned back on again.

BECAUSE OF THE SEVERE CONSEQUENCES, INCLUDING DEATH, OF NOT PROPERLY LOCKING OUT ELECTRICITY SUPPLIES DURING MAINTENANCE, THE SUPERVISOR SHOULD ENSURE THAT THERE IS ONLY 1 KEY FOR THE LOCK USED TO LOCK OUT THE POWER SUPPLY.

For identification, locks may be color coded to indicate different crews or shifts.

The Supervisor should maintain the master key and list of key numbers, and should keep an extra key to each lock for his department. The master key should not be loaned out under any circumstances.

No matter what method is used to lock out power, strict discipline and constant supervision should be employed during any equipment maintenance work.

Power Lock Out Checklist

1. Alert the operator of the equipment.

2. Before starting the work on an engine, motor, line shaft or other power transmission equipment or power-driven machine, make sure it cannot be set in motion without your knowledge.

3. Place your own padlock on the control switch, lever, or valve, even if someone has locked the control panel before you. You will not be protected unless you put your own padlock on it. (Another maintenance person could remove their lock and then someone else could start the equipment if they were not aware of maintenance work being done.)

When you are finished working, remove your own padlock. Never permit someone else to remove it for you. Be sure you are not exposing someone else to danger by removing your padlock

Daily Instructions

Primary & Secondary Chamber Burners: (01-002.D & 02-002.D)

Do not store flammable or hazardous materials in the vicinity of fuel burning appliances.

Improper installation, adjustment, alteration, service or maintenance can cause property damage, personal injury or death.

Burner shall be installed and maintained in accordance with manufacturer's requirements as outlined in the Burner manual, local codes and authorities having jurisdiction.

INSTRUCTION 01/02-002.D.02: INSPECTING THE FUEL LINES

1. Visually inspect all fuel lines to the Primary and Secondary Burner as well as to the Waste Oil burner for any leaks.

2. If any leaks are observed tighten or replace the piping section where the leak is occurring

Refractory: (05-001.D)

When working with the refractory make sure you use the proper tools; wear goggles, approved dust mask and gloves

INSTRUCTION 05-001.D.01: INSPECTING THE REFRACTORY

Ensure power is locked out.

Please follow all instructions outlined in *Zero Mechanical State & Lock Out Instructions.*

1. Open Primary Chamber door by unlatching all clamps.

2. Tie-off door to open position to ensure that it will not close unintentionally.

3. Enter Primary Chamber and check the refractory for shrinkage, any gap between the modules greater than 2.5 cm should be patched with the blanket refractory

4. Check for any exposed metal between the modules, if metal is exposed make sure to patch area with blanket material (PN: 501803) or new module (PN: 433026) (*CMI 4.4.2/05-001A & 4.4.2/05-001B)*Weekly Instructions

Primary & Secondary Chamber Blowers: (01-001.W & 02-001.W)

Do not attempt any maintenance on a fan unless the electrical supply has been completely disconnected and locked.

Please follow all instructions outlined in *Zero Mechanical State & Lock Out Instructions.*

A fan can windmill despite removal of all electrical power therefore, take extra care when working with fans in the system.

The rotating assembly should be blocked securely before attempting maintenance of any kind.

INSTRUCTION 01/02-001.W.01: DAMPER CRANK ARM

Check to see that the damper crank arm is connected to the damper and the rod.

Ensure mechanical linkage on damper is tight, if loose tighten with wrench.

PRIMARY BLOWER

1. Air Proving Switch
2. Modutrol Motor
3. Motor Crank Arm
4. Damper Crank Arm
5. Rod
6. Damper

SECONDARY BLOWER

1. Air Proving Switch
2. Modutrol Motor
3. Motor Crank Arm
4. Damper Crank Arm
5. Rod
6. Damper

A. Damper Crank arm and connection to Damper and Rod

INSTRUCTION 01/02-001.W.02: SLIDE GATES

Check to see if slide gates move freely.

1. Move slide gate in and out to ensure free movement. If sticking, use lubricant to loosen. Lubricant should be rated for a high temperature (>150°F) application.

2. Gates must be opened to allow under fire air to enter the chamber. They should only be closed to reduce air in abnormal operating conditions.

1. Sample Primary Chamber Slide Gate Open

2. Sample Primary Chamber Slide Gate Closed

3. Sample Secondary Chamber Slide gate Open

Primary & Secondary Chamber Burners: (01-002.W & 02-002.W)

Do not store flammable or hazardous materials in the vicinity of fuel burning appliances.

Improper installation, adjustment, alteration, service or maintenance can cause property damage, personal injury or death.

Burner shall be installed and maintained in accordance with manufacturer's requirements as outlined in the Burner manual, local codes and authorities having jurisdiction.

Switch off the electrical power. Please follow all instructions outlined in *Zero Mechanical State & Lock Out Instructions.* Cover must be removed to perform maintenance on burners.

ECO WASTE SOLUTIONS

INSTRUCTION 01/02-002.W.02: PRIMARY & SECONDARY BURNER MAINTENENCE

Refer to Burners manuals in section 8 of this manual

Primary Burner: Riello RS 28/M
Secondary Burner: Riello RS 100/M

Air Compressor: (03-001.W)

INTAKE AIR. Can contain carbon monoxide or other contaminants. Will cause serious injury or death. This air compressor is not designed, intended or approved for breathing air. Compressed air should not be used for breathing air application.

HAZARDOUS VOLTAGE. Can cause serious injury or death. Disconnect power and bleed pressure from the tank before servicing.

MOVING PARTS. Can cause serious injury. Do not operate with guards removed. Machine may start automatically. Disconnect power before servicing.

HOT SURFACES. Can cause serious injury. Do not touch. Allow to cool before servicing. Do not touch hot compressor or tubing.

HIGH PRESSURE AIR. Bypassing, modifying or removing safety/relief valves can cause serious injury or death. Do not bypass, modify or remove safety/relief valves. Do not direct the air stream at body. Rusted tanks can cause explosion and severe injury or death. Drain tank before each use. Drain valve located at bottom of tank.

RISK OF BURSTING. Use only suitable air handling parts acceptable for pressure of not less than the maximum allowable working pressure of the machine.

INSTRUCTION 03-001.W.02: INSPECTING AIR FILTERS IN AIR COMPRESSOR

Refer to Husky Compressor manual Model HLA3706056 in section 8 of this manual

INSTRUCTION 03-001.W.03: CLEANING COMPRESSOR & CHECKING SAFETY VALVE

Cleaning

A dirty compressor will cause abnormally high temperature and result in oil carbonization on valve components.

Clean all external parts of the compressor with compressed air. Concentrate the cleaning on the external fins where dirt can accumulate as cooling air is forced across them.

Refer to to Husky Compressor manual Model HLA3706056 in section 8 of this manual for:

Checking Safety Valve
Draning the Tank

Thermocouple: (05-002.W)

When working with electrical components, ensure lock out instructions are being followed.

Thermocouple Assembly

Thermocouple Element

ECO WASTE SOLUTIONS

INSTRUCTION 05-002.W.01: INSPECT THERMOCOUPLE FOR DAMAGE

Turn main power to the system off - Remove thermocouple and visually inspect for damage. If damaged, see *CMI 4.4.1/05-002A*

1. Primary Thermocouple (TC1)

2. Secondary Thermocouple (TC2) on Secondary Chamber Container

3. T-stack thermocouple (TC3not shown)

Monthly Instructions

Primary & Secondary Chamber Blowers: (01-001.M & 02-001.M)

Do not attempt any maintenance on a fan unless the electrical supply has been completely disconnected and locked. In many cases, a fan can windmill despite removal of all electrical power. The rotating assembly should be blocked securely before attempting maintenance of any kind.

Please follow all instructions outlined in *Zero Mechanical State & Lock Out Instructions.*

INSTRUCTION 01/02-001.M.01: CHECK FAN WHEEL

1. Check the fan wheel for any wear or corrosion, as either can cause catastrophic failures, if left in operation.
2. The wheel can be accessed one of two ways.
   a. Remove the blower assembly from the unit and look down the outlet of the blower.
   b. Remove the damper assembly from the inlet of the blower and inspect by looking through the inlet of the blower.
3. Check also for the build-up of material which can cause unbalance resulting in vibration, bearing wear and serious safety hazards.
4. Clean the wheel as required.
5. If replacement is necessary follow these steps:
   a. Remove damper assembly from the unit
   b. Remove the blower assembly
   c. Remove the blower housing around the wheel
   d. Loosen all set screws that are located on the wheel.
   e. A puller may be required if the wheel hasn't been removed for some time.
   f. Ensure the shaft "key" is installed on the shaft before installing the new wheel.
   g. When installing a new wheel, the wheel should be positioned in the housing with the correct spacing between the edge of the inlet cone and the wheel. The wheel to cone clearance on the Primary Blower is 0.3175 cm.
   h. Ensure that the wheel is installed securely before reassembling the blower assembly.
   i. Install the blower assembly
   j. Install the damper assembly

ECO WASTE SOLUTIONS

INSTRUCTION 05-001.M.01: INSPECT REFRACTORY

1. Ensure power is locked out.
2. Open Primary Chamber door.
3. Fasten door open, ensuring it will not close by its own weight.
4. Enter Primary Chamber and check the refractory for shrinkage, any gaps between the modules greater than 2.5 cm should be patched.
5. Fix gaps with supplied blanket by stuffing material into opening. (See *CMI 4.4.2/05-001A)*
6. Check for any exposed metal, if metal is exposed make sure to patch area with blanket material or new module. (See *CMI 4.4.2/05-001A* & *4.4.2/05-001B)*
7. Pay special attention to areas where the junction boxes are located, as any excessive heat may melt the wires within the box.
8. While inside the Primary Chamber using a flashlight check the status of the Dome and the center piece which consist of 3 holes.

Some cracking is normal, however if pieces are missing or have fallen out, (See *CMI 4.4.2/05-001E)*

Waste Oil Burner: (02-003.M)

Failure to maintain and / or improper servicing by unqualified personnel will adversely affect the proper, safe operation of your burner, will reduce the service life of your burner and will void your warranty

INSTRUCTION 02-003.M.01: INSPECT ELECTRICAL COMPONENTS

1. Check all electrical components for any heat damage.
2. If heat damage is observed remove and replace.

ECO WASTE SOLUTIONS

1. Slide out burner
2. Undo Bolt

3. Loosen Bolt

4. Open hinged hatch to access front components

INSTRUCTION 02-003.M.02: INSPECT HEATER ELEMENT

1. Remove heater element from casing and inspect for build-up

2. Clean any deposits.

3. If damaged, heater element needs to be replaced. Removal involves the following steps:
    a. Remove all electrical connections attached to the heater block identified in Picture #3 below.
    b. Remove all the bolts attaching the heater to the burner housing.
    c. Remove all fuel line connections.

d. Remove the heater element and install the new one. (PN: 33173)
e. Reinstall the heater block.

4. When reinstalling the heater element always ensure the element will be restarted immersed.

NEVER use the inline heater dry

1. Unscrew (yellow) electrical connection

2. Remove cover screw

3. Open hatch cover to expose heater element

Air Compressor: (03-001.M)

INTAKE AIR. Can contain carbon monoxide or other contaminants. Will cause serious injury or death. This air compressor is not designed, intended or approved for

breathing air. Compressed air should not be used for breathing air application unless treated in accordance with all applicable codes and regulations.

HAZARDOUS VOLTAGE. Can cause serious injury or death. Disconnect power and bleed pressure from the tank before servicing. Compressor must be connected to properly grounded circuit. Do not operate compressor in wet conditions. Store indoors.

MOVING PARTS. Can cause serious injury. Do not operate with guards removed. Machine may start automatically. Disconnect power before servicing. Lockout/Tagout machine.

HOT SURFACES. Can cause serious injury. Do not touch. Allow to cool before servicing.

HIGH PRESSURE AIR. Bypassing, modifying or removing safety/relief valves can cause serious injury or death. Do not bypass, modify or remove safety/relief valves. Do not direct air-stream at body. Rusted tanks can cause explosion and severe injury or death. Drain tank before each use. Drain valve located at bottom of tank.

RISK OF BURSTING. Use only suitable air handling parts acceptable for pressure of not less than the maximum allowable working pressure of the machine.

INSTRUCTION 03-001.M.01: CHECK FASTENERS FOR TIGHTNESS

1. Check all fasteners for tightness (tighten as required).

2. Check the safety valve manually, by pulling ring or lever, to make sure that it is not stuck. Allow the ring to snap back to normal position

Quarterly Instructions

Refractory: (05-001.Q)

When working with the refractory make sure you use the proper tools; wear goggles, dust mask and gloves

Please follow all instructions outlined in *Zero Mechanical State & Lock Out Instructions.*

INSTRUCTION 05-001.Q.01: INSPECT DOOR GASKETS

1. Open Primary Chamber door.
2. Fasten door open, ensuring the door will not close on its own.
3. Inspect door gasket for damage.
4. Replace any damaged segments of door gasket (PN: 462007) if necessary. Cut out the damaged section and replace with new door gasket. See *CMI 4.4.2/05-001C*.
5. Doors must close tightly and securely, ensuring a good seal.

Sample Primary Door (refractory lined)

1. Primary Door Gasket

ECO WASTE SOLUTIONS

INSTRUCTION 05-001.Q.02: INSPECT REFRACTORY FOR SHRINKAGE

1. Ensure power is locked out.
2. Open Primary Chamber door.
3. Fasten door open, ensuring they will not close on their own.
4. Enter Primary Chamber and check the refractory for shrinkage, anything greater than 2.54 cm should be patched.
5. Check to make sure the anchoring of the modules is still strong and intact, if any modules seem loose replace complete module with new module.

A. REMOVAL: Remove existing Module (physically pull away existing refractory from underlying Module Anchor).

B. Remove welded stud from steel casing (cut with hack saw or other device between Module Anchor and Furnace Casing/Shell).

Figure 1: Side view of the Weld Loc Module

Figure 2: Stud Gun with rasp and Torque Tube.

A. INSTALLATION: Once the new module (PN: 433026) is in place take the stud gun (PN: ECO-STUD) with rasp to the Torque Tube and drill into place.

B. Once it has tightened the Torque Tube should come off with the drill.

Paint: (05-003.Q)

Ensure proper ventilation and proper equipment is being used when using any paint product.

INSTRUCTION 05-003.Q.01: INSPECT AND MAINTAIN EXTERIOR PAINT

1. Maintain paint exterior to protect metal from heat and corrosion damage. This includes all components in the system including containers and incinerator components.

2. If discoloration is noted and painting needs to be performed, on areas where paint will be applied, you must do a light sanding before application.

3. Follow paint manufacturer's application instructions which will include surface preparation, priming and painting.

Paint Specifications:

Incinerator Paint: This is the paint coated directly on the incinerator shell. This includes the following components:

1. Primary Chamber
2. Secondary Chamber
3. Hot Stack Section (Black)

Finish needs to be able to withstand temperatures in the 650-750°F (340-400°C) range.

Parts: There are no paint specifications for each individual component. This is left up to the discretion of the customer.

Yearly Instructions

Refractory: (05-001.Y)

When working with the refractory make sure you use the proper tools; wear goggles, dust mask and gloves

INSTRUCTION 05-001.Y.01:
CHECK DOOR GASKET ALONG PRIMARY CHAMBER DOOR

1. If required replace the door gasket. The gasket can last over 2 years but will depend on the careful use by the operator when loading and unloading.

2. Remove the damaged section of door gasket from door and reinstall new gasket (PN: 462007)

Sample Primary Door (refractory lined)

Primary Door Gasket

Electrical: (05-004.Y)

When working with electrical components ensure lock out instructions are being followed

Please follow all instructions outlined in *Zero Mechanical State & Lock Out Instructions.*

ECO WASTE SOLUTIONS

INSTRUCTION 05-004.Y.01: CHECK LIMIT SWITCHES

NOTA System must not be running or in cool down to perform this inspection.

1. Open Primary Chamber door and check top view screen on the HMI Panel view to ensure that it indicates door is open.

2. Close Primary Chamber door and check top view screen on the HMI Panel View to ensure that it indicates door is closed.

3. All limit switches located on the unit are checked this way.

4. Replace limit switches (PN: 802T-APE) if necessary.

Primary Chamber Limit Switch

Waste Oil Burner Out Limit Switch

Waste Oil Burner In Limit Switch

Waste Oil Burner In Limit Switch

Waste Oil Burner Out Limit Switch

Waste Oil Burner: (02-003.Y)

Failure to maintain and / or improper servicing by unqualified personnel will adversely affect the proper, safe operation of your burner, will reduce the service life of your burner and will void your warranty

INSTRUCTION 02-003.Y.01: SERVICING THE METERING PUMP

1. Remove the pump head cover.
2. Remove the screen and wash it.
3. Remove and discard the used gasket.
4. Install a new gasket.
5. Replace the screen and pump head cover.

For more detail, refer to OEM Waste Oil Burner Manual

Corrective Maintenance Instructions (CMI)

The following instructions relate to the replacement or correction (fixing) of components of the EWS Mobile Incinerator Package.

These Corrective Instructions are grouped in this section by the following:

4.4.1 General Corrective Maintenance Instructions
4.4.2 Refractory Corrective Maintenance Instructions
4.4.3 Primary & Secondary Burner Corrective Maintenance Instructions
4.4.4 Primary & Secondary Blower Corrective Maintenance Instructions
4.4.5 Waste Oil Burner Corrective Maintenance Instructions
4.4.6 Main Control Panel Corrective Maintenance Instructions

As per the *Preventive Maintenance Instructions Manual*, the following table is utilized to identify the components of the system that require corrective maintenance.

System Component		**Identification number**	
Thermocouple		**05-002**	
	Replacing Thermocouple		4.4.1/05-002A
Limit Switch		**05-005**	
	Limit Switch Replacement		4.4.1/05-005A
Refractory		**05-001**	
	Wall Refractory: Gaps between the Modules		4.4.2/05-001A
	Wall Refractory: Replacement of the Modules		4.4.2/05-001B
	Door Gasket		4.4.2/05-001C
	Castable Refractory		4.4.2/05-001D
	Temporary Repair of Castable		4.4.2/05-001E
Primary Blower		**01-001**	
	Air Proving Switch Replacement		4.4.4/01-001A
	Damper Calibration		4.4.4/01-001B
	Modutrol Resistor Replacement		4.4.4/01-001C
	Damper Crank Arm Replacement		4.4.4/01-001D
	Motor Replacement		4.4.4/01-001E
	Modutrol Motor & Transformer Replacement		4.4.4/01-001F
Secondary Blower		**02-001**	
	Air Proving Switch Replacement		4.4.4/02-001A
	Damper Calibration		4.4.4/02-001B
	Modutrol Resistor Replacement		4.4.4/02-001C
	Damper Crank Arm Replacement		4.4.4/02-001D
	Motor Replacement		4.4.4/02-001E
	Modutrol Motor & Transformer Replacement		4.4.4/02-001F
Waste Oil Burner		**02-003**	
	Waste Oil Burner		4.4.5/02-003A
	Waste Oil Burner Parts Replacement		4.4.5/02-003B
	Waste Oil Burner J-Pump Replacement		4.4.5/02-003C
Main Control Panel		**03-010**	
	Main Control Panel		4.4.6/03-010A
	Reboot PLC		4.4.6/03-010B

LIMIT SWITCH REPLACEMENT (4.4.1/05-005A)

1. Loosen the 2 screws holding the limit switch in place.
2. Remove limit switch, replace with a new one (PN: 802T-APE).
3. Take arm off of old body and mount to new.
4. Tighten the 2 screws holding the limit switch body.

REPLACING THERMOCOUPLE (4.4.1/05-002A)

The thermocouple will require routine replacement. The environment inside the incinerator will erode the protection tube to the point of failure. If the element is exposed to this environment it will be destroyed and will need to be replaced.

1. Unscrew thermocouple lid and remove wires.
2. Remove protection tube. To aid with this a vise and a pipe wrench will be needed.
3. Remove element and replace with new element (PN: TK-K08B-0100-S) and protection tube (PN: TA-A427A-K08B-010).

4. Reinstall on incinerator.

5. After installation turn power back on. Observe the temperature reading of the thermocouple you were just working on. If the wires were installed incorrectly the temperature will read the opposite temperature. (I.e. 20°C would read as -20°C). If this is the case open the thermocouple housing and switch the wires.

Refractory Corrective Maintenance Instructions

When working with the refractory make sure you use the proper tools; wear goggles, dust mask and gloves

WALL REFRACTORY: GAPS BETWEEN THE MODULES (4.4.2/05-001A)

The ceramic block refractory will shrink over time exposing the exterior metal shell. These gaps need to be filled in with ceramic refractory blanket.

1. Identify gaps in the chamber that are larger than 1” in width between the modules or if you can see exterior shell.

2. With a Utility knife cut a length of ceramic blanket (PN: 501803) that will fit in the gap between the modules.

3. Stuff the blanket into the space with a straight edge or ruler.

WALL REFRACTORY: REPLACEMENT OF MODULES (4.4.2/05-001B)

Excessive damage to a section of refractory may necessitate the replacement of modules in the incinerator. Such damage is largely due to mechanical wear. The following diagram walks through the removal and installation of new modules.

A. REMOVAL: Remove existing Module (physically pull away existing refractory from underlying Module Anchor)

B. Remove welded stud from steel casing (cut with hack saw or other device between Module Anchor and Furnace Casing/Shell)

Figure 2: Stud Gun with rasp and Torque Tube (part of module assembly).

Figure 1: Side view of the Weld Loc Module

C. INSTALLATION: Once the new module is in place take the stud gun with rasp to the Torque Tube and drill into place.

D. Once it has tightened the Torque Tube should come off with the drill.

DOOR GASKET REFRACTORY (4.4.2/05-001C)

The door gasket will degrade over time and will need to be replaced. The bottom of the door will see more degradation due to the waste burning in that vicinity.

1. Identify the damaged section of gasket that will need to be removed
2. With a utility knife cut out the section that needs to be replaced.
3. A new piece of gasket (PN: 462007) will need to be cut the same length as the removed piece.
4. With contact cement coat the gasket on one side and the door section and install.

CASTABLE REFRACTORY (4.4.2/05-001D)

Operators will notice that the castable refractory will show signs of minor cracking. The minor cracking is normal. Large sections of castable should not separate from the rest of the monolithic cast. Such occurrences are largely due to a sudden impact from machinery or dropping of the units themselves. Mortar is supplied to help with a temporary repair while a permanent repair is resolved.

TEMPORARY REPAIR OF CASTABLE (4.4.2/05-001E)

1. Find the pieces of castable refractory that have separated.
2. Clean both the pieces of refractory and the area where the separation occurred.
3. Spread an even amount of high temperature mortar (PN: 452036) on the pieces and the area of separation.
4. Put the pieces back where they originated and support as necessary for a minimum of an hour while the mortar cures.

LEVEL SWITCH REPLACEMENT (4.4.3/01-002G & 02-002G)

The level switch is located in the Waste Oil Tank.

NOTE

Tank does not have to be emptied to replace.

1. Unplug the level switch.
2. Disconnect the cord and remove the level switch.
3. Replace level switch (PN: FS301-01) and reconnect the cord.
4. Plug in the level switch.

Primary & Secondary Blower Corrective Maintenance Instructions

Do not attempt any maintenance on a fan unless the electrical supply has been completely disconnected and locked. In many cases, a fan can windmill despite removal of all electrical power. The rotating assembly should be blocked securely before attempting maintenance of any kind.

Primary Blower Assemblies are not a commonly repaired part on the incinerator. Parts within this assembly will need to be repaired or replaced. They are outlined below.

Primary Blower

1. Air Proving Switch
2. Modutrol Motor
3. Motor Crank Arm
4. Damper Crank Arm
5. Rod
6. Damper

Secondary Blower Assemblies are not a commonly repaired part on the incinerator. Parts within this assembly will need to be repaired or replaced. They are outlined below.

Secondary Blower

1. Air Proving Switch
2. Modutrol Motor
3. Motor Crank Arm
4. Damper Crank Arm
5. Rod
6. Damper

AIR PROVING SWITCH REPLACEMENT (4.4.4/01-001A & 02-001A)

1. Ensure all power is locked out.
2. Remove wiring from switch.
3. Remove tubing from switch.
4. Unscrew screws at the two locations and remove switch.
5. Reinstall new switch (PN: SML8221210034) complete with tubing and wiring and then retighten.
6. Turn power back on.

DAMPER CALIBRATION (4.4.4/01-001B & 02-001B)

Sometimes the damper linkage will slip when the connections become loose (Items 3,4,5 in the Secondary Blower photo) In order to ensure that the linkage is correctly calibrated the operator will need to look at the display screen on the control panel while the unit is in operation

1. Read the %Open value on the control panel operator interface for the Primary Blower.
2. During operation the damper is factory preset to be 0% open, or fully closed.
3. Look inside the damper (Item 6) and ensure that the linkage is completely closed.
4. If it is, then this maintenance is complete.
5. Should the damper be open even a small percentage the linkages are to be loosened and the damper adjusted to be completely closed, and then retighten.

MODUTROL RESISTOR REPLACEMENT (4.4.4/01-001C & 02-001C)

The Modutrol resistors are located inside the top lid of the Modutrol motor. Remove the lid to the Modutrol motor by unscrewing the top four (4) screws. The connection between the control panel and the Modutrol is made with a small white connector with 3 terminals. Jumpered between these terminals is the resistors.

Remove and replace the resistors one at a time to ensure the correct resistors are replaced. You identify the correct resistor by examining the color band on the center node of the resistor. Replace like resistors.

DAMPER CRANK ARM REPLACEMENT (4.4.4/01-001D & 02-001D)

The crank arm will only need to be replaced if the arm is damaged due to misuse. Identify the damper crank arm (Item #4 in the picture on the previous page).

Identify the location of the linkage on the rod and the damper arm with a marker, so the new crank arm will be in the same spot when reinstalled. Remove the connections to the crank arm and replace with the new one (PN: 26026G) and ensure it is in the same spot as the old one.

MOTOR REPLACEMENT (4.4.4/01-001E & 02-001E)

Information on replacing the motor can be found in the OEM manual New York Blower, Installation, Maintenance and Operating, IM-160 Junior Fans.

MODUTROL MOTOR & TRANSFORMER REPLACEMENT (4.4.4/01-001F & 02-001F)

To replace the Modutrol motor all power to the system need to be off as you will need to expose electrical connections. First get the new motor and orientate the motor in the same direction as the old motor. Identify where the conduit is connected on the old motor and punch the connector holes for the new motor.

Removal

1. Remove all electrical terminations and remove the transformer.
2. Install the transformer in the new Modutrol motor.
3. Remove all conduit connections on the motor.
4. Remove the damper arm and linkage from the motor.
5. Unbolt the motor from the damper, and ensure all nuts and bolts are kept for the new motor install

Install

1. Bolt the new motor in the same orientation as the old motor.
2. Install the damper arm and linkage to the motor
3. Install all conduit connections

Terminate all electrical connections the same as the old motor.

REPLACE THE BLOWER CONTACTOR 4.4.4/01-001G

1. Turn Main Disconnect Switch into the OFF position.
2. Open Panel.
3. Remove the wires.
4. Pull the retaining clip up.
5. Tilt contactor forward and remove.
6. To reinstall tilt new contactor until it clicks back in.
7. Pull the retaining clip back down to lock.
8. Reinstall wires.
9. Close panel.
10. Turn power back on.

Waste Oil Burner Corrective Maintenance Instructions

Failure to maintain and/or improper servicing by unqualified personnel will adversely affect the efficient and safe operation of your burner, will reduce the service life and will void your warranty.

WASTE OIL BURNER HEATER ELEMENT CLEANING / REPLACEMENT (4.4.5/02-003A)

Slide out burner undo bolt

Loosen hinge hatch bolt

Open hinged hatch to access front components

Unscrew (yellow) electrical connection

Remove Cover Screw

Open hatch cover to expose heater element

Remove heater element from casing and inspect for build-up.

Clean any deposits.

When reinstalling the heater element (PN: 33173) always ensure the element will be restarted immersed in waste oil. A dry element while in operation will reduce the life of the element.

WASTE OIL BURNER PARTS REPLACEMENT (4.4.5/02-003B)

The waste oil burner has the following parts that may need replacing:

Part Description	Part #	Description of replacement
Primary Control	33391	Locate remove and reinstall new one
Igniters Transformer	33189	Locate remove and reinstall new one
CAD Cell	33116	Locate remove and reinstall new one
Fan Squirrel Cage	31113	Locate remove and reinstall new one
Blower Motor	33337	Locate remove and reinstall new one
Retention Head	11427	Locate remove and reinstall new one
Air Pressure switch	33057	Locate remove and reinstall new one
Heater Block	26090	Locate remove and reinstall new one
Air / Oil Solenoid	32322	Locate remove and reinstall new one

WASTE OIL BURNER J-PUMP REPLACEMENT (4.4.5/02-003C)

Waste Oil Burner Pump (J-Pump) Sample location

Removing the pump requires the power to be off to the system. When this is done complete the following step:

1. Open the junction box on the side of the motor of the pump. Disconnect the electrical connections and remove the conduit connection
2. With fuel containment cloth remove the waste oil connection from the pump inlet and outlet.
3. Unbolt the pump. Remove from the chamber

Install the new pump by reversing the above steps.

MAIN CONTROL PANEL (4.4.6/03-010A)

All control panel diagnostics are to be completed by certified or trained technicians. Electrical drawings / diagrams are provided to aid electricians with any diagnostics.

REBOOT PLC (4.4.6/03-010B)

Turn Main Disconnect to the off position on the front of the Control Panel. Turn the main disconnect back on.

General Description - Thermal Oxidation Concept

The **CA100WO** Incinerator system consists of a **Primary Chamber** and a **Secondary Chamber** (also known as the Afterburner). Both chambers are vessels constructed of steel with a special insulating liner known as refractory.

The **Primary Chamber** has a front door for loading of waste material and for the removal of residual ash.

The waste is loaded into the **Primary Chamber** until it is ¾ full. Once ¾ full the **Primary Chamber** is sealed and the combustion cycle begins. This type of system is known as *batch-fed* processing.

Primary Chamber

To begin the process of burning the solid waste, the **Primary Chamber Burner** is used to elevate the temperature of the **Primary Chamber** to ignite the waste. Once the **Primary Chamber** reaches a temperature of 650-850 ^{o}C (1200-1560 ^{o}F), by using a **Thermocouple** to measure the temperature of the **Primary Chamber**, the burn process becomes self-fuelling and the burner will shut off. To save fuel and control temperatures, only when the energy contained within the waste is depleted, will the burner periodically turn on.

The **Primary Chamber** operates under *controlled temperature* conditions. The amount of heat released, from the burning of the waste, is controlled by limiting the air into the **Primary Chamber** to less than what is required to complete combustion. This is described as *starved air* conditions. With controlled air and temperature the waste is dried, heated and burned thereby releasing moisture and volatile components. The non-volatile, combustible portion of the waste is burned in the **Primary Chamber** to provide heat while the non-combustible portion accumulates as ash. These conditions ensure that the waste is allowed to fully combust and is rendered sterile. In the end, the waste volume is reduced by over 90%.

Remaining in the **Primary Chamber** are non-combustibles, such as metal and glass, and carbonaceous residue. The incoming air, subjecting the non-combustibles to high temperatures, further burns the carbonaceous residue. The result is an oxidized ash product.

Controlling the gas velocity through the system is an important factor in limiting pollution. The gases flowing from the **Primary Chamber** are a result of the interaction of the air with the waste during the controlled burning process. Both the quantity and velocity of the gas product vary according to chamber temperature conditions and the type of waste being burned. The integrated controls for the **Primary** and **Secondary Chamber** act to minimize peaking activity thus controlling pollution automatically.

The combustion gases released in the **Primary Chamber** then pass into the **Secondary Chamber** through a turbulent mixing zone where ignition takes place and additional combustion air is provided to complete the burning process.

Secondary Chamber

As waste burns in the **Primary Chamber**, gases containing the products of combustion are pulled continuously into the high temperature zone of the **Secondary Chamber** where the oxidation reaction of the combustible products is completed.

The **Secondary Chamber** controls the temperature at 1000°C (1832 ^{o}F), using a **Thermocouple,** which constantly measures the temperature inside the chamber. The temperature readings are monitored by the system's PLC and the PLC will initiate operational changes such as increasing or decreasing the speed of the **Secondary Chamber Blower** and the output of the **Secondary Chamber Burner**.

The **Secondary Chamber Blower** air is introduced into the **Secondary Chamber** by an air ring manifold that surrounds the **Secondary Chamber**. The manifold has small air jets called tweers that open into the **Secondary Chamber** at the side walls and create a powerful vortex of excess air to mix the incoming gases and ensure complete combustion. The flow of air is tightly managed by the control system using a Variable Frequency Drive (VFD) to control the speed of the fan and modulating motors on the blower inlet dampers.

The **Secondary Chamber Blower** is extremely important as it creates the turbulence required to mix the gases and oxygenate them. This fosters the high efficiency combustion required to break hydrocarbon chains into carbon dioxide and water vapour. It also acts to cool the **Primary Chamber** and prevent temperature overruns.

Secondary Chamber Burner is similar to the burner used in the **Primary Chamber** except that it has a much higher output and it is self-modulated over a broad range for very precise temperature control.

The **Secondary Chamber** is sized to allow two seconds of retention time. This is the time that the gases from the **Primary Chamber** are retained in the **Secondary Chamber** before they exit to the next stage. Two seconds of retention is considered to be ideal to destroy any harmful organic hydrocarbons produced from the **Primary Chamber**.

Protecting the Environment

Why Incinerate

As society becomes more environmentally conscious, environmental regulations on the proper disposal of waste has become more stringent. As a result, incineration has become an environmentally responsible and socially acceptable alternative for handling waste at the point of need. However, incineration does not eliminate the need to landfill waste but it does reduce the amount of waste that must be placed in landfills.

Primary Advantages of incineration are:

- It greatly reduces the weight and volume of waste material that must be disposed of in landfills
- It destroys organic materials that may be harmful or that may be degradable to harmful materials in landfills
- The incinerator sterilizes the waste; that is, the high temperatures in incinerators can destroy any pathogens that may be in infectious waste materials
- The incinerator destroys animal or human pathological wastes that the general public finds objectionable to handle or see.

Environmental Concerns

The general public will not accept incineration as an option for treating waste of any kind, if they do not believe that it is safe environmentally. The primary concerns are about air pollutants produced by the incinerator and the toxicity of the residual ash.

Air Pollutants of Concern

Particulate matter may be defined as fine liquid or solid matter such as dust, smoke, mist, or fumes found in the gaseous emissions from the incinerator. Particulate matter emissions may have a dark or light color. Particulate matter emissions can be described in terms of opacity. Opacity is the degree to which light is obscured by a polluted gas (a clear window has 0 percent opacity while black paper has 100 percent opacity). Opacity may be measured with the naked eye or using an opacity monitor. Particulate matter is a problem because it can cause or aggravate respiratory problems in humans. It also creates aesthetic problems since it is readily noticed and is a nuisance because of soiling of exposed surfaces on houses and cars.

Hydrochloric HCl acid is generated when polyvinyl chloride (PVC) plastic (usually clear plastic) material is burned in the incinerator. The appearance of a white plume or cloud a short distance above the stack indicates that HCl is condensing. The major concerns about HCl are that it causes respiratory problems in humans, contributes to acid rain problems, and causes material damage to metals and concrete.

Toxic metals include cadmium, arsenic, beryllium, chromium, nickel, lead, and mercury. These metals may be found in municipal wastes. These metals are known to be hazardous to human health.

Organic compounds are compounds that contain primarily carbon and hydrogen and may also contain other elements such as oxygen, nitrogen, and chlorine in smaller amounts. Some organic compounds are known to cause or are suspected of causing cancer and are considered hazardous air pollutants. The public's primary concern is related to dioxin and furan emissions, but other organic compounds such as benzene and vinyl chloride may be emitted.

Carbon Monoxide (CO) also is generated during combustion if the combustor is not operated properly. (Your automobile generates some amount of CO.) CO is toxic to humans if concentrations are high enough, and it also is an indicator of combustion quality.

Solid Waste Ash Quality

One of the major objectives of incineration is to generate a high quality ash for land disposal. All pathogens should be destroyed, and almost all organic material should be completely burned. Ideally, no large chunks of unburned waste material (other than metals or glass) should remain in the waste. A measure of ash quality is "burnout," which is the percentage of organic material remaining in the waste. For example, a burnout of 95 percent means that the ash can contain only 5 percent organics. Adequately burned and quenched ash may be disposed of in a sanitary (municipal) landfill. The ash should be stored in covered containers or kept wet prior to transport to the landfill to prevent 'fugitive \ emissions.' Individual landfills may have requirements that must be followed in order for your waste to be accepted. You should familiarize yourself with these requirements to prevent refusal of the waste.

The Operator – Your Role

It is the operator's role and responsibility to protect the environment by:

1. Complying with all emission limits and operating practices specified in the permit to operate.
2. Minimizing emissions of particulate matter, HCl, toxic metals, carbon monoxide, and organic compounds through proper incinerator;
3. Operating the incinerator to generate high quality ash that is sterile and can be disposed of in landfills;
4. Minimizing particulate matter emissions from ash handling;
5. Disposing of ash properly by sending it to appropriate disposal sites; and
6. Performing the regular maintenance inspections to catch any operational problems early.

Basic Combustion Principles

The Combustion Process

Combustion of MSW is a chemical reaction. In the incinerator, organic materials and oxygen react rapidly and violently to produce combustion gases and energy in the form of heat and light.

$$\text{Organic Solid Material + Oxygen} \xrightarrow[\text{Heat}]{} \text{Combustion Gas + Solid Residue + Energy(Heat)}$$

For the reaction to begin and to keep going, all three elements - organic material, oxygen, and heat-must be present. The organic material used in the reaction comes from two sources, waste and auxiliary fuel. Some organic material is contained in most solid waste types. Depending on the fraction of organics and the specific organic composition, the waste may be adequate to sustain combustion. Auxiliary fuel may be used to maintain combustion if the waste material does not contain enough organic material to maintain high temperatures. The combustion reaction between the organic material and oxygen that causes the organics to burn will occur only after the temperature of the organic material is raised to the point that combustion can begin.

Energy in the form of heat is required to raise the temperatures of the incinerator chamber and organic material and O_2. Initially, this energy usually is supplied by the pilot and auxiliary fuel burners. After the system is in full operation, the energy released from the burning waste often is adequate to maintain these high temperatures.

Fate of Combustion Air

The oxygen needed for the combustion reaction is supplied by the ambient combustion air. Combustion air is supplied to the combustion chambers through air ports by a forced draft fan, by an induced draft fan, or by natural draft. In general, this air contains about 21 percent oxygen (O_2) and 79 percent nitrogen (N_2), so about 21 percent of the total combustion air fed to the incinerator is oxygen that is available to react with the organic material in the waste and fuel. The nitrogen passes through the chamber mostly unreacted; some nitrogen oxides are formed.

Oxygen Reaction

Solid waste contains two types of organic materials

1. Volatile Matter
2. Fixed Carbon

These two types of materials are involved in distinct types of combustion reactions, and the operating variables that control the two types of reaction are different.

Volatile matter is that portion of the waste that is vaporized (or evaporated) when the waste is heated. Combustion occurs after the material becomes a gas. The combustion variables that influence this reaction are gas temperature, residence time, and mixing.

- A minimum temperature is needed to start and sustain the chemical reaction.
- Residence time is the length of time, generally measured in seconds that the combustion gas spends in the high temperature combustion chamber. The residence time must be long enough for the reaction to be completed before it leaves the high temperature zone.
- Turbulent mixing of the volatile matter and combustion air is required to ensure that the organic material and oxygen are well mixed.

Fixed carbon is the nonvolatile organic portion of the waste. The combustion reaction is a solid-phase reaction that occurs in the primary chamber (although some materials may burn in suspension). Key operating parameters are temperature and solids retention time.

- The solids retention time is the length of time that the waste remains in the primary chamber.

Products of complete combustion are:
- Carbon dioxide
- Water

One example of volatile waste is backyard charcoal grill with starting fluid. The starting fluid is highly volatile. When put on the charcoal and ignited with a match, it rapidly volatilizes and burns. The charcoal contains less volatile matter and primarily burns slowly as a fixed carbon bed.

Operating Factors Related to Combustion

The three operating factors that have the greatest effects on the combustion reaction are:

- Combustion airflow rate and distribution,
- Operating temperatures, and
- Waste feed rate and characteristics.

These three factors are all related. Controlling them controls the combustion reaction. The two key questions about combustion air are:

- How much combustion air is needed to sustain the combustion reaction?
- What happens if there is too much or too little combustion air?

Stoichiometric Air

In the chemical reaction between organic materials and oxygen, the amount of oxygen required under ideal or "perfect" conditions to burn all of the organic materials with no oxygen left over is called the stoichiometric (or theoretical)-oxygen level. The amount of combustion air associated with that oxygen level is called the stoichiometric air level. At stoichiometric air level the combustion gas would contain no oxygen because it would all be used in the combustion reaction.

Substoichiometric Air

Airflows less than those required at stoichiometric levels are called deficient air or substoichiometric starved-air levels. Under starved-air conditions, the combustion gas would again contain no oxygen, but organics also would remain because combustion is not complete.

Excess Air

Air flows greater than those required at stoichiometric levels are called excess-air levels. Typically an incinerator operates with an overall 140 to 200 percent excess air level. That is, the incinerator operates with one and one-half to two times more air than required at stoichiometric levels. Excess air is used to assure that enough oxygen is available for complete combustion.

Control of Temperature as a Function of Air Level

Maximum combustion temperatures are always attained at stoichiometric conditions. As the amount of excess air is increased above the stoichiometric point, the temperature in the incinerator drops because energy is used to heat the combustion air. If the amount of combustion air is too great, the temperature drops below “good combustion temperature," and undesirable combustion products are generated as a result of incomplete combustion. As the amount of excess air is decreased, the combustion temperature increases until it becomes maximum at the stoichiometric point. Below the stoichiometric point, the temperature decreases because complete combustion has not occurred.

CONTROL OF TEMPERATURE AS A FUNCTION OF EXCESS AIR

The relationship of how combustion air level can affect temperature has just been shown. Temperature also plays an important role in the combustion of waste. Temperatures need to be maintained at levels high enough to ensure pathogen destruction and to sustain the combustion reaction. However, temperatures that are too high also cause problems. Continuous exposure of the combustor refractory to high temperatures is generally not desirable because it can cause the ash to fuse and can cause damage to the refractory.

Waste Characteristics

The primary characteristics of the waste that affect the combustion reaction are:

- The heating value

- The moisture content
- The chlorine content

Different wastes have different heating values and moisture contents. They will affect the combustion process.

The HEATING VALUE of a waste is a measure of the energy released when the waste is burned. It is measured in units of Btu/lb (J/kg). A heating value of about 5,000 Btu/lb (11.6×10^{-6} J/kg) or greater is needed to sustain combustion. Wastes with lower heating values can be burned but they will not maintain adequate temperature without the addition of auxiliary fuel. The heating value of the waste can be used to calculate total heat input to the incinerator where:

Heat Input (Btu/h) = Feed Rate (lb/h) x Heating Value (Btu/lb)

Heat input to the incinerator will affect temperature. More heat input yields higher temperature. Heat input also will affect air requirements; more air is required (1 SCF/100 Btu).

MOISTURE is evaporated from the waste as the temperature of the waste is raised in the combustion chamber. It passes through the incinerator, unchanged, as water vapor. Evaporation of moisture uses energy and reduces the temperature in the combustion chamber.

CHLORINE in plastics or solvents in the waste feed will react to form hydrochloric acid (HCl). This HCl can be an emission problem. It can create corrosion problems of the equipment downstream from the incinerator.

The heating value (Btu value) and moisture varies widely. Compare plastics (high Btu, no moisture) to Beddings, shavings, etc. to Anatomical

Summary of Key Operation Factors Affecting Combustion

1. Key factors are interrelated.
2. Air quality/distribution
3. Sufficient air for complete reaction
4. Distributed to promote mixing
5. Mixing
6. Assure contact of oxygen and organics
7. Temperature
8. High enough to sustain combustion
9. High enough to have complete reaction
10. Residence/retention time
11. Sufficient time to allow reaction to complete

Waste characteristics also are important

- Heating value
- Measure of energy released
- Heat input determines air required
- Moisture content
- Requires energy to vaporize water
- Chlorine content

- Affects HCl emissions

Products of Combustion Reaction

Complete Combustion

The primary products of waste incineration are:

- Combustion gases
- Solid residue (ash)
- Energy

The primary objectives of the combustion process are to generate an ash residue that is sterile (free of pathogens) and does not contain unburned, recognizable wastes; and to minimize air pollutants in the combustion gas stream.

The organic materials that enter the incinerator with the waste and fuel are primarily made up of carbon, hydrogen, and oxygen. Ideally, these organic materials react with oxygen in the combustion gas to form carbon dioxide and water vapor. The chemical reaction for this ideal situation is

$$\text{Organics} + O_2 + \text{Heat} \longrightarrow CO_2 + H_2O + \text{Heat}$$
(C, H, 0)

This ideal reaction represents complete combustion.

Incomplete Combustion

However, this ideal reaction does not occur in operating waste combustion systems. Factors that lead to a less than ideal reaction are poor mixing, too little combustion air, and low temperatures. Under those conditions products of incomplete combustion are emitted with the stack gases. The most common product of incomplete combustion is CO. Another product of incomplete combustion that often is emitted under poor mixing conditions or high temperature, low excess air conditions, is elemental carbon (or soot). The soot particles are very fine and generally result in high opacity at the combustion stack. Other products of incomplete combustion that cause concern because of their health impacts are hazardous organic compounds such as benzene, dioxins, and furans. Although these compounds are not found in the waste, under incomplete combustion conditions they can be formed as intermediate combustion products.

The waste feed also includes inorganic materials; generally, they are not involved in the combustion reaction. The inorganic materials in the waste feed (ash) are either retained in the ash or are emitted as particulate matter in the combustion gas. Air velocities in the combustion bed are controlled to reduce the amount of inorganic material entrained (picked up by) the combustion gas and emitted with the combustion gas. If combustion is not complete, organics will remain in ash; this is typical…it is atypical to have 100 percent combustion of ash bed. Under poor conditions (low temperature, low turbulence in ash bed) the ash may have pathogens present, the ash may not be sterilized.

Combustion Indicators

The following indicators can be used to monitor combustion quality.

Opacity

The opacity of the combustion gas stream is a measure of the degree to which the stack gas plume blocks light.

- High opacities indicate high emissions.
- Opacity is primarily caused by noncombustible ash or uncombusted carbon (soot) in the flue gas.
- High opacities can indicate poor mixing or low levels of combustion air.
- High opacities also may be generated by high levels of HCl emissions or poor burner operation in the secondary chamber.

If a large amount of water vapor is present in the combustion gas, the water can condense when it cools as it leaves the stack forming a dense white "steam plume." This is not an indicator of poor combustion and should not be confused with a black or white smoke plume caused by soot or acid gases. Opacity can be visually determined by a person or measured by an instrument.

Other indicators which provide information about combustion conditions are measurements of the combustion gas oxygen and CO levels. However, these measurements require instruments and most facilities do not have those instruments.

Ash Quality

Visual appearance of ash can be an indicator of combustion problems. If an incinerator is operating properly, little organic material will remain in the ash. Whitish gray ash indicates better burnout and less carbon than black. The extent of organics combustion can be measured by the quantity of combustible materials remaining in the ash. Noted increases in combustibles in the ash indicate a combustion problem which may include bed temperatures that are too low, improper distribution of combustion air in the bed, or insufficient waste retention times.

ASSEMBLY & INSTALLATION PROCEDURES

CA 100WO

Corporate Office:

Eco Waste Solutions

5195 Harvester Road, Unit 14

Burlington, ON, Canada L7L 6E9

Tel: 905-634-7022 Fax: 905-634-0831

Email: info@ecosolutions.com

Web: www.ecosolutions.com

Introduction

The unit will require assembly in the field. Consult Eco Waste Solutions (EWS) for component weights so that properly sized cranes are available at the site for unloading and erecting.

This incinerator has been knocked down for packaging and transportation inside 20' shipping containers.

Lifting lugs are provided on stacks, and major accessories. These lugs should be used in setting the pieces into position. Do not attach lifting chains or cables to piping or mounting flanges as they may be damaged. Avoid dragging lifting gear across painted surfaces as this will cause damage to the high temperature paint. When placing the incinerator into position be extremely careful not to subject the refractory to mechanical shock as this may result in refractory damage.

Additional utility connections are as follows and some instructions follow at the end of this section:

- Electrical
- Propane Gas

Incinerator Assembly and Installation Procedures

Assembly of CA 100WO Incinerator System

Reference: Drawing: CA 100 WO 00 General Arrangement (GA)

Step 1: Foundation for building
The incinerator's building and related components must be installed on a level concrete pad or compacted gravel pad. It is recommended that appropriate consultation with civil engineers and/or architects is taken before designing an appropriate foundation.

Please refer to EWS supplied drawings BUILDING FLOOR.

Preparation of 14'x14' floor to accommodate CA-100 WO

- Set up and bolt C-channel and I-Beams together using lettered markings as a guide

Install (weld) the provided ¼ "check plate for floor surfaces.

Once the building floor is installed with the checkered plate welded on the appropriate foundation, the primary chamber and the secondary chamber can be placed on the building floor.

Step 2: Primary Chamber

The location of the *Primary Chamber* is already determined in the building floor. Set *Primary Chamber* into position. Shim with steel shim plates until level. Install anchor bolts in all six (6) locations on the base.

Primary Chamber

Step 3: Insulating Blanket

Install the provided insulating blanket along top edge of Primary dome.

Dome Side/Top

Dome: Top View

Dome: Side View

Step 4: Secondary Chamber Door

With the door attached to the secondary chamber, disassemble the guides attached to the door. These guides will ride on the rails shipped loose

Rails

Install the rails to the secondary chamber using the pre-installed threaded Brackets

This secondary chamber door can only be opened when the incinerator is cold and for maintenance purposes.

Step 5: Secondary Chamber

Install the *Secondary Chamber* aligned (see below) with the *Primary Chamber* as per the installation drawings. Lower *Secondary Chamber* slowly onto *Primary Chamber* compressing the insulating blanket between the *Primary* and the *Secondary* Chambers. Align bolt holes and bolt together using hardware provided.

At this point, the CA 100WO Model Incinerator should look as follows:

Step 6: T-Stack and Stack Sections

Install stack gaskets between stack sections.

Install refractory-lined *T-Stack Section* on top of the *Secondary Chamber* using the hardware provided. Then install the next three *Stack Sections* as per the drawing using hardware provided.

ECO WASTE SOLUTIONS

T-Stack and Stack Sections

This is a Sample Photo <u>only</u> of Erection of the Stack Sections

Step 7: Building Assembly

At this point EWS recommends the erection of the building around the CA-100WO as per '*Ellipta Assembly Instructions'* in O&M Manual.

- Sheet metal siding panels will require clipping to fit around stack. Weld two piece ring flange to T-Stack just above roof line.
- Attach flashing provided between ring flange and building roof.

Collar installed to stack section

Flashing sections to be installed over the collar and attached to the building roof

Step 8: Primary Chamber Burner

Have a licensed gas fitter, install *Primary Chamber Burner* and gasket in Primary Burner port using the hardware provided.

Step 9: Secondary Chamber Burner

Have a licensed gas fitter; install *Secondary Chamber Burner* and gasket in secondary burner port using the hardware provided.

Step 10: Primary Chamber Blower

Install the *Primary Chamber Blower* mount frame using the hardware provided.

Install the *Primary Chamber Blower Assembly* including motor and damper on top of the mount frame using the hardware provided.

Primary Chamber Blower

Step 11: Secondary Chamber Blower

Install the *Secondary Chamber Blower* mount frame using the hardware provided.

Install the *Secondary Chamber Blower Assembly* including motor and damper on top of the mount frame using the hardware provided.

Secondary Chamber Blower

Step 12: Thermocouples

Install the three (3) ¾" *Thermocouples* at positions indicated in red below in Primary Chamber, Secondary Chamber and T-Stack (not shown in picture).

NOTE When wiring the thermocouples there must be no splices between the Main Control Panel and the thermocouple. Use the thermocouple wire provided.

On the Thermocouples the red wire is NEGATIVE and the Yellow is POSITIVE.

Step 13: Viewports

Install three (3) 2" threaded *viewports* at positions indicated in red below on the *Primary Chamber* door, the right hand side of the *Secondary Chamber* burner and on the right hand side of the *Primary Chamber* burner.

NOTE The viewports should be hand tightened only, do NOT over tighten.

Step 14: Waste Oil Burner

Refer to Clean Burn OEM manuals

- Mount the waste oil burner slide frame assembly onto the lower section of the Secondary with hardware provided.
- Mount the waste oil burner (Clean Burn) on the slide frame assembly on the red bracket.

Accumulator Block

Step 15 Propane Gas and Waste Oil Connections

<u>Reference</u>: Drawing CA 100-WO-00 General Arrangement (GA)
Drawing CA 100-WO-01 P&ID

The Propane gas tank and evaporator are pre-assembled on a skid; the gas trains for the burners are pre-assembled to be installed in the building. The connection from the heavy ends trap in the tank skid to the building, including the low pressure regulator for the burners' gas train has to be carried on-site (by client's qualified contractors). There must be a proper clearance according to local regulations from the tank/evaporator skid to the building . The complete propane installation has to be inspected and approved by the local authority (client's scope).

Propane Skid

Propane Burners gas Train

NOTE All Propane Gas connections to be done by a certified technician and should satisfy all local codes (all lines to be pressured tested), including the distance between the incinerator system and the tank.

Step 16: Electrical Connections
Reference: Electrical Drawings provided

NOTE All electrical connections, terminations and conduit installation to be done by a certified electrician and should satisfy all local codes.

Most of the internal wiring of the incinerator was completed at the factory and dismounted for shipping.

The wiring necessary on-site (by client's contactors) is:

- From the *power source* to the *Main Control Panel*
- From the incinerator's building to the propane vaporizer
- From the *Main Control Panel* to components Junction Box
- From the breaker box to the propane vaporizer
- From the *Main Control Panel* to the waste oil tank

Step 17: Start-Up

NOTE **CAUTION**: Do not attempt to place the equipment into operation until an EWS Service Technician has checked out all equipment and interlocks.

Upon completion of mechanical erection, interconnection of equipment and provisions of utilities as described above, arrangements should be made with the EWS field service department for scheduling of a service technician for initial start-up.

An EWS representative must perform start-up of all incinerator systems unless specifically arranged otherwise in writing by EWS.

Attempts to start-up incinerator systems by the buyer without prior written approval may result in revocation of all expressed or implied warranties.

Web: www.ecosolutions.com

Important Information

Proper operating and maintenance procedures must be followed in order for the CA Model Incinerator system to perform at maximum efficiency.

Do not attempt to start or operate this equipment until this Operator Manual is read thoroughly and is understood.

The equipment has been designed with many safety features, however, like all thermal processes; this equipment is not free from the inherent hazards of high temperature processes.

Safety procedures and precautions must be followed at ALL times during operation.

There are safety procedures outlined in this Manual, however, no amount of written instruction can replace good judgment and safe operating practices.

Responsibility for the safe operation and maintenance of the equipment supplied rests solely on those operating it.

There are many engineered features incorporated into the CA Model Incinerator system to free the operator of repetitive chores. They do not, however, relieve the operator of maintenance responsibilities. In order to maximize the operating life of the equipment, it is strongly recommended that the maintenance procedures, be followed diligently. It is advisable to keep an equipment log for recording maintenance activities along with unusual operation.

NOTE

In the event that the equipment is not operating in the normal manner, contact Eco Waste Solutions immediately at (905) 634-7022. It is important to report problems as soon as they are noticed to minimize damage that faulty operation could cause.

Design Specification Criteria

The **CA100WO** incinerator system was designed specifically for the **Brucejack** project under **Eco Waste Solutions (EWS)** proposal **PRB-CA 100** presented on December 3, 2014 and based on information provided by Pretivm Resources Ltd.

The **Brucejack Project** is a gold mine located 65 km north of Stewart in northwestern, BC; the EWS team designed an incinerator with the following criteria in mind.

Waste Description

The solid waste material generated at this mine camp is described as mainly camp and kitchen waste.

EWS assumes that the waste material is typical of mixed camp waste, non-hazardous solid waste consisting of food-waste, kitchen waste including packaging, cardboard, wood waste, and general refuse.

- Inappropriate materials including, but not limited to, reactive/explosive chemicals and items containing heavy metals will not be processed in the incinerator proposed herein.

Project

The **Brucejack Project** is a gold mine located 65 km north of Stewart in northwestern, BC.

Waste Description

This Ca100 WO incinerator is required to process camp waste as follows:

CA 100 Incinerator Package

	CA 100
Maximum Incinerator Processing Rate	182 kg/batch
Hours of operation	Burn Cycle 3-5 hours, Cool-Down Cycle 4 hours
Maximum Waste processed in 24 hours (operated twice per day only)	364 kg per day (over 2 batches)

To address the need of disposing any waste oils generated at site a **Waste Oil Burner (WOB) Package,** has been integrated as part of the incinerator system to dispose of up to 5gal/hr of waste oil

ECO WASTE SOLUTIONS

EWS Waste Assumptions

In addition to daily waste generation rates, one of the most critical assumptions to be made in planning a waste management/incineration disposal system is the estimation of the waste density. With batch incinerators in particular, waste density is critical to determining the size of the incineration system.

We have based our assumptions upon our experience but should site specific data be available, it should be considered in the design assumptions.

Description	Total Moisture Content	Density	Higher Heat Value
Mixed Solid Waste	Up to 40%	10-15 lbs/ft^3 160-240 kg/m^3	6,500 BTU/lb 15,150 KJ/kg

Waste Oil Specifications

- The Waste Oil burner is designed to burn up to 5 gal/hr of the following fuels:

Used crankcase oil up to 50 SAE
Used transmission fluid
Used hydraulic oils
#2 fuel oil
#4 fuel oil
#5 fuel oil

NOTE: Used oils may contain other substances, including gasoline, which may hinder performance.

- Hazardous wastes, such as chlorinated solvents, are NOT to be mixed with your used oil

NOTE

This incinerator was only designed for the type of waste and amount of waste mentioned above. It is important that the waste quantities and characteristics described above are processed in the incinerator. Otherwise, the incinerator system will not operate properly.

General Operating Overview

The operation of the **CA 100WO Waste Incinerator** follows 7 general steps that take place over a 12-hour period.

Although all 7 steps are critical in the general operation of the incinerator system, this section of the manual focuses on **Step 1, Step 3** and **Step 4** and how to start the system and monitor it during operation.

This section will also cover **Step 7** on how to use the historical charts, store incinerator data, and access incinerator historical information for record keeping purposes.

Monitoring and Data Acquisition System

Overview

The **PLC** automatically monitors the entire process and some system inputs are recorded and logged for record-keeping purposes and also allows for historical trending of key operating conditions.

The integrated **PLC** in the Main Control Panel monitors and records the following:

1. Temperature sensors
2. Differential pressure sensors with transmitter (draft)
3. Monitoring of burner faults
4. Fan amperage monitoring via current transducer and VFD
5. Door position interlock monitoring
6. High temperature limit and interlock
7. Damper positions

All data can be transferred to storage by using the USB flash memory installed in the back of the HMI

Data Logging

Data from the Incinerator is logged automatically on the HMI and will need to be manually retrieved from the HMI.

Using Historical Charts

Accessing Historical Information

a. It is recommended that a dedicated folder be set on the destination computer that is used for storing data from the Incinerator Package (e.g. “Incinerator Data”)

b. Copy the data file “**RSView Enterprise Viewer.EXE”** from the USB Flash Memory (extracted from the back of HMI, in the panel) to this dedicated directory and rename the file with the date to easily access previous week’s information.

c. **“”**.

d. To open data, double click on the RSView Enterprise Viewer application. From the File menu select Open. Make sure you are searching in the folder containing the historical data files.

e. In the Open dialogue box, in the File Name type “***.***” to view all files. Click on the specific Text Document that you wish to open.

f. Once the data is open, it will look similar to the following:

Date	Time	MilTm	Marker	TagIndex	Status	Value

Saving Data to Excel

a. To save the data in a Microsoft Excel format – with the data open (as above) from the File menu select Save As and select the directory where you wish to save the file. Make sure you have a logical name in the File Name field (it will default to the same file name as the TXT file you have opened). Make sure CSV is selected in the "Save as Type" drop down box and select the Save button.

b. To view the file in Microsoft Excel, open the Excel application and from the File menu, select Open and then make sure that "Files of Type" is on "Text Files"

c. Choose the file you wish to open and select "Open" from the dialogue box. The file is now open in Excel.

HMI Operator Interface

Main Control Panel Components

Number	Name	Purpose
1	**Main Disconnect Switch**	Isolates the incinerator from its source of electric power.
2	**HMI Operator Interface**	Displays various screens reflecting system performance.
3	**Control Power ON**	1. Green light indicates the control power in the panel is on. 2. Pushing it if the **Emergency-Stop** is out will turn on the control power.
4	**Emergency Stop Pushbutton**	Stops the cycle if it is on and disables any possibility of starting it.
5	**USB Port**	Allows access to PLC and HMI

The HMI Operator Interface

The **HMI Operator Interface** controls the operation of the incinerator directly from the **Main Control Panel.**

The **Main Menu** screen displays all the available options for viewing the system in operation.

The **HMI** has a touch-screen and items can be selected by touching them on the screen.

Main Menu

The first screen the operator will view is the **Main Menu** (see below).

Front View

When the ***Front View*** button is selected, an overview of the incinerator and related components is displayed. This shows key temperatures, flows, and other indicators of what is happening in the process in a real-time basis.

NOTE

The system will not start if there are alarms or faults present.

At any time, touch **Main Menu** to go back to the main screen.

Primary and Secondary Status

When the ***Primary Status* or Secondary Status** button is selected from the **Main Menu,** a screen will display the status of all the operating parameters of the Primary Chamber or Secondary Chamber accordingly, such as the temperatures and the time remaining in the cycle, as well as displaying other informational items such as status of the door and blowers, etc.

The operator can change the burn time of the cycle by selecting “BURN TIME” and entering a time (in minutes). The operator may do this over time to either prolong the burn time, or decrease the burn time depending on the waste mixture; for example a very wet batch of garbage will take more time to burn than a dryer batch of waste.

At any time, touch **Main Menu** to go back to the main screen.

Primary Status

Secondary Status

Alarm History

When the ***Alarm History*** button is selected a screen will display the last 128 faults with the date & time of occurrence.

The operator can press the *CLEAR ALARM HISTORY* to clear all of the faults, if they wish to. This does not affect the record-keeping feature of the system.

At any time, touch **Main Menu** to go back to the main screen.

Overview of Historical Charts

The **HMI** operator interface monitors and records (every minute) critical operating parameters of the incinerator system like the temperature, motors, draft, load weights and alarms. Each operating parameter has its own graphic display for the operator to view, at any given time. Each display can easily be selected from the **Main Menu** of the **HMI**. The display will show the specific data collected from previous burn cycles.

This **Incinerator Data** is important for regulatory purposes and for general operating purposes.

Temperature History

For example, when the ***Temperature History*** button is selected, the screen will display the trend in temperature during the operation of the system, include date & time of occurrence of that specific temperature.

Motor Currents History

When the ***Motor Currents History*** is selected a screen will display the motor currents from the Primary Burner and the Secondary Burner, in AMPS, during the operation of the system, including date & time of occurrence of that specific motor current.

Draft History

When the ***Draft History*** button is selected a screen will display the draft during the operation of the system, include date & time of occurrence of that specific draft trend.

Standard Daily Operating Procedures

Daily Circular Inspection

1. Check that all valves leading to the burners are open
2. Check that the slide gates on the blowers are open
3. Check waste oil valves from tank to burner are open and lines leak free
4. Check that all circuit breakers are in the “ON” position
    - In the main breaker panel
    - For the propane skid, check the circuit breaker at the back of the building to ensure the vaporizer has power. The vaporizer should feel warm to the touch
5. Fix any items found incorrect.

Incinerator Daily Start up

1. Ensure that manual slide gates for each blower are in the open position for free airflow into the **Primary and Secondary Chambers**

Primary Chamber Blower Manual Slide Gate Open

Secondary Chamber Blower Manual Slide Gate Open

2. If propane odour is noticed, visually inspect the burner piping to ensure that there are no gas leaks.
3. Ensure the draft gauge connection is tight and sealed. This is tubing located in the back of the **Primary Chamber.**
4. Unlatch clamps on the **Primary Chamber** door, open and secure in the open position

5. Ensure the Primary Chamber floor is cool (less than 50°C). Remove all the ash from the previous burn and store ash in ash bins.

If the floor is hotter than this temperature the waste may spontaneously catch on fire during loading.

6. Tips for loading. The following loading procedure will decrease burn time and allow for more uniform burn.
   a. Load the less dense waste first
   b. Load dry waste first. Placing wet waste near the top of the Primary Chamber allows moisture to evaporate early in the cycle.
   c. Place waste on the weigh scale, the operator has to manually record the waste weight being loaded to the CA 100 model incinerator
   d. Then, the operator must take the waste and load it into the Primary Chamber.
   e. The operator returns to the weigh scale with some more waste and repeats Steps c and d. This entire procedure is repeated until the maximum load weight is reached, in this case 182kg per load cycle

NOTE

No more waste should be loaded into the Primary Chamber after the load has reached the maximum weight, or in the case of lower density waste, the chamber is ¾ full (the burner requires open space in front of it to allow for a proper flame)

NOTE

Do not throw the waste towards the sides of the Primary Chamber. Doing so will damage the ceramic fiber refractory.

NOTE

Load only the waste stream that the system has been designed for. DO NOT load a lot of high BTU rated waste for one burn (i.e. do not load three (3) 5 gallon pails of bacon grease or wood only). Doing so will result in excessive temperatures in the system reducing the life of the refractory.

NOTE

Do not load the Primary Chamber above its rated capacity by weight or above the burner opening.

7. Lock the **Primary Chamber** Door and ensure all latches are properly engaged.
8. Proceed to the **Main Control Panel.**

NOTE

The burn time will be set to the previous burn, if you wish to change the set time, proceed to the System Status screen and click on the BURN TIME button. The minimum number of minutes you can enter is 180 (3 hours). When you have finished, the time will be displayed in minutes beside the BURN TIME button

NOTE

The burn time value (in minutes) determines the length of the burn cycle before cool down cycle starts.

9. Check that the primary door shows closed on the **HMI SYSTEM STATUS** screen or the **HMI FRONT VIEW** screen**.**

   Check that no alarms are displayed. The **HMI** will display any faults, which need to be cleared before the system can start.
10. Check that the EMERGENCY STOP BUTTON is out.
11. Check that the **green control light is illuminated.**

Do not use this incinerator to burn waste oil only. Always burn a complete load of solid waste when burning waste oil

12. On the **HMI** System Status Screen make sure to select Solid Waste or Solid Waste and Waste oil (System Mode)
    a. SOLID WASTE SELECTED: Ensure the Waste Oil burner is pulled out and the Limit switch is made. ABB HMI Side View will show burner is out. ***Make sure to put the PLUG into the opening of the Secondary Chamber***.
    b. SOLID WASTE AND WASTE OIL SELECTED: Ensure the plug is removed from opening and push the Waste Oil Burner all the way in, making connection with the Limit Switch in, the HMI Side View will show burner is in.

Remove plug

Push all the way in until front limit switch is made

13. On the **HMI** Primary Status Screen press the “START SYSTEM” button. The following steps will automatically take place, controlled by the **Main Control Panel**:
    a. SOLID WASTE SELECTED
        I. The **Primary Blower and Secondary Blower** will purge the system for 2 minutes.
        II. The **Secondary Burner** will purge for safety, and upon completion will ignite.
        III. Once the **Secondary Chamber** temperature reaches 1000°C, the **Primary Burner** will purge for safety and upon completion will ignite.
        IV. The burn time will start counting down when the temperature in the **Primary Chambers** reaches 427°C.
    b. SOLID WASTE AND WASTE OIL SELECTED
        I. The **Primary Blower and Secondary Blower** will purge the system for 2 minutes.

ECO WASTE SOLUTIONS

II. The **Secondary Burner** and **Waste Oil Burner** will purge for safety, and upon completion they will ignite.

III. Once the **Secondary Chamber** temperature reaches 1000°C, the **Primary Burner** on will purge for safety and upon completion will ignite.

IV. The burn time will start counting down when the temperature in the **Primary Chambers** reaches 427°C.

NOTE

The Main Control Panel System will maintain proper operating conditions for the CA100WO.

After the burn cycle is completed the system will enter the cool-down cycle and the following things will occur:

- Primary Chamber & Secondary Chamber burners OFF
- Secondary Chamber Blower OFF
- Primary Modutrol 100% open
- Primary Blower ON

Once fully cooled and the temperature is below 50°C, proceed to the **Primary Chamber Clean Out Procedures**.

Primary Chamber Clean Out Procedures

Operators responsible for loading and cleaning out incinerators should wear appropriate protective equipment, including eye protection, dust masks, heavy gloves and safety shoes with puncture-proof toes and soles to avoid injury.

Although the ash from the system is considered sterile and will not contain microorganisms, it may contain a quantity of sharp objects, such as broken glass and other sharps which may not be fully destroyed in the burning process, and may thus still pose a hazard to persons who clean out the ash and residues. Also removing the ash does create dust particles in the air. Dust should not be inhaled. The operator must wear dust protection safety gear.

Please follow these steps when the cycle is complete:

1. When the internal temperature of the **Primary Chamber** has cooled to less than 50°C, lock out the power to the system on the **Main Control Panel** by moving the main disconnect to the “OFF” position.
2. Unlock all door latches on the access door to the **Primary Chamber.**
3. While standing in front of the **Primary Chamber** door, slowly open the door to allow clear entry. Secure **Primary Chamber** Door in the OPEN position.

4. Clean the **Primary Chamber** by using ash handling tool(s) and proper safety equipment (not provided).
5. Inspect the interior of the **Primary Chamber** for wear and inspect around the door seals to ensure the door will maintain a tight seal upon closure.
6. Check the air inlet holes and remove any obstructions if necessary.
7. Inspect the door seals to ensure there are no gaps between the door gasket and the door jamb.
8. Close the **Primary Chamber** access door by clamping each latch until it is tight.
9. Clean the inspection **View Port** (glass) with a mild soap and water. To clean the view port, unscrew it by hand and re-tighten by hand.

In Case of Emergency

1. Go to manual Slide Gates on the **Primary Chamber**, located just after the blower and close them all the way. This will help to put the fire out in the **Primary Chamber** out.
2. Check alarms to see what the problem is.
3. Do not open the door of the **Primary Chamber** unless the temperature inside the chamber is below 50°C.
4. Call a certified technician to fix the problem and/or consult with **Eco Waste Solutions Customer Service Department at 905.634.7022, toll free 1-866-326-2876.**

Start Up After Power Failure

1. Once the power is restored turn breaker (main disconnect) back on.
2. The Operator Interface and PLC will begin a boot up procedure. Wait until the **HMI** on the **Main Control Panel** has booted up before turning the control power to the panel back on by pressing the Control Power ON button.
3. When the power is restored to the **Main Control Panel**, the button should illuminate.
4. If the system was interrupted during a burn cycle, on the **HMI SYSTEM STATUS** screen press the "**START BURN**" button to restart the system. If the system was interrupted during cool-down cycle, it will resume the cycle where it left off.
5. Ensure the propane vaporizer circuit breaker is "ON" and check if any of the propane pressure switches require reset at the burner valve train and at the top of the vaporizer.

Dealing with Warning and Faults

Troubleshooting

The burn cycle will not start if one of the following conditions exists:

1. The system still is in “cool-down” cycle. Wait until the “cool down” cycle is complete.
2. There is a fault in the system as indicated on the **HMI**.
3. Loss of power due to any one or more of the following:
    - The main disconnect (see image) is off or there is no electrical power. Turn on the disconnect switch or check why there is no power.

Power is OFF in this position

Power is ON in this position

- An open circuit breaker or blown fuse. Check the breakers and fuses, replace any that are defective.
- The EMERGENCY STOP is pushed in. Twist the EMERGENCY STOP button to unlock, and then push the CONTROL POWER ON button. The CONTROL POWER BUTTON should now be illuminated green.

4. If on the Main Control Panel HMI the **Primary Chamber** door is not closed, the door has not been shut properly. Adjust the limit switch lever arm if necessary. Check the limit switch and that the wiring is in working order.

5. If fuel pressure is low, system will not start. This is an indication the vaporizer is not “ON”

6. If fuel pressure is high, the pressure switches will trip. The pressure switched will have to be reset and if they trip again the propane regulators will have to be checked.

PLC Processor Problem

- Check the run light on the PLC processor. If it is on the PLC it is ready.
- “OK LIGHT” is green = Controller is OK.
- “OK LIGHT” is Red Flashing = this is a recoverable fault, check the PLC processor. This fault is very unlikely to occur.
- OK LIGHT is Red = this is a non-recoverable controller fault. Cycle Power. The OK LED should change to flashing red. If LED remains solid red, replace the PLC. This fault is very unlikely to occur.
- DCHO light is green = this indicates the PLC processor has lost the program. The PLC is equipped with a flash card that will automatically load the program back onto the PLC.

ECO WASTE SOLUTIONS

Possible Problems, Causes and Solutions

Problem	Causes	Solutions
Blower Fails to start	Over load tripped, blown fuse	Turn power off. Open Panel and reset overload. Check fuse and replace.
	Motor starters or contactor coil is burnt out	Locate contactor for Blower and visually observe if the contactor is pulled in. Use a volt meter to check for voltage across the coil If there is voltage across the coil and the contactor is not pulled in, replace the contactor.
Secondary Burner won't ignite	Bad Electrodes	Refer to Maintenance Section of this manual.
	Fuel Pressure fault	Ensure there is enough fuel in the tank Reset pressure switches on burner fuel train Reset vaporizer switch (on top of vaporizer) Ensure vaporizer is turned ON
	Fuel Line Leak	If propane odor is noticed, close all valves, tighten any fittings or replace leaking piping.
	Door Switch not making contact	Make sure main door is closed and latched shut. Make sure limit switch is hitting striker plate.
	Burner main switch is turned off	Turn switch on.
	Burner alarm has been tripped	Acknowledge burn alarm and then hit the reset button on control panel.
	Bad Thermocouple	Replace thermocouple.
Primary Burner won't ignite	Bad Electrode	Refer to Maintenance Section of this manual.
	Fuel Pressure Fault	Ensure there is enough fuel in the tank Reset pressure switches on burner fuel train
	Fuel Line Leak	If propane odor is noticed, close all valves, tighten any fittings or replace leaking piping.

ECO WASTE SOLUTIONS

Problem	Causes	Solutions
	Door Switch not making contact or broken	Make sure main door is closed and latched shut. Make sure limit switch is hitting striker plate.
	Secondary temperature not at 1000°C	Wait until Secondary temperature is at 1000°C and try again.
	Burner main switch is turned off	Turn switch on.
	Burner alarm has been tripped	Acknowledge burn alarm and then hit the reset button on control panel.
Persistent Black Smoke	Insufficient air supply to Secondary Chamber to completely consume emissions	Check to ensure combustion air blower/damper assembly is operating properly.
	Secondary Chamber is not hot enough.	Check that the Secondary temperature is operating at required temperature set point.
	Secondary Chamber is not hot enough.	Too much draft, open barometric damper.
	Overloading or loading highly volatile material	Decrease load size on next batch (confirm by weighing), ensure the waste mix is correct.
	Burner failure	Check burner operation – if no flame or a poor flame is visible through the flame view port adjust air/fuel ratio.
	Operation at too high a Primary Chamber temperature	Check/decrease primary chamber combustion air.
Smoke coming out of Primary	Too much air	Check dampers on primary blower.
	Too much volatile material loaded	Decrease load size on next batch to ensure the waste mix is correct.
	Low draft	Close the barometric damper in the t-stack section
	Primary Chamber temperature too high	Waste loaded may not be a good mix of heat value .
Too much fuel usage	Too much secondary combustion air	Check/reduce secondary combustion air.
	Too much air infiltration	Reduce air flow by adjusting the damper.
	Fuel leakage	Check fuel trains and burners for fuel leakage.

Problem	Causes	Solutions
	Wet waste	Spread wet waste with other waste through several loads – do not charge all of the wet waste at one time.
	Excessive draft	Check/reduce draft – check door seals and other seals for leakage adjust damper.
	Burner setting too high	Check air/fuel mix.
Incomplete burnout/poor ash quality	Build-up around air holes – clogged with ash from previous burn	Check around air holes and clean.
	Poor draft	Draft should be -0.25-0.06 KPa (or 1.0-0.25"W.C).
	Too much wet waste – overloading system	Spread wet waste with other waste through several loads – do not charge all of the wet waste at one time.
	Insufficient burn time	Allow longer burn time period.
Waste Oil Burner		
System will not start when Solid is selected	Waste Oil burner is inserted into the Secondary Chamber	Remove Waste Oil burner assembly from the Secondary Chamber. And place the plug into the port
System will not start when Solid and Waste Oil are selected	Waste Oil burner is not inserted into the Secondary Chamber	Remove the plug from the port and insert the Waste Oil burner assembly into the Secondary Chamber.

Possible Alarms (Faults)

#	ALARM (System Fault)	SOLUTION
1	The Primary Chamber Thermocouple is faulted	See corrective maintenance procedures. Section 7 on this manual
2	The Secondary Chamber thermocouple is faulted	See corrective maintenance procedures. Section 7 on this manual
3	The Secondary Stack Thermocouple is faulted	See corrective maintenance procedures. Section 7 on this manual

#	ALARM (System Fault)	SOLUTION
4	The primary burner is faulted	The primary burner has failed to light when it received a signal telling it to start. To reset the burner, press the reset button located on the Burner. Ensure the vaporizer is ON, the pressure switches are not tripped and all valves from tank to burner are open If this does not start the burner, refer to Supplier Catalogue (Riello Burner) Section 8 of this manual.
5	The secondary burner is faulted	The secondary burner has failed to light when it received a signal telling it to start. To reset the burner, press the reset button located on the Burner. Ensure the vaporizer is ON, the pressure switches are not tripped and all valves from tank to burner are open If this does not start the burner refer to Supplier Catalogue (Riello Burner) Section 8 of this manual.
6	The system has shut down due to primary blower low air flow. 	Visually examine the primary blower for any obstructions that may be causing low air flow. Check slide gate located between Primary chamber and blower, ensure it is open. Check damper assembly, ensuring modutrol crank arm is still connected and that butterfly damper is open, allowing air flow. Air proving switch may be defective. Refer to Section 6 of this manual. There are two ports on the air flow switch marked V and P. Ensure the inlet tube is attached to the port marked “P” for pressure. V stands for vacuum. Ensure the “V” port is open to atmosphere and is not blocked. If no air restriction is observed (i.e. blockage in the tube) change the air proving switch. Refer to Section 7 of this manual.

#	ALARM (System Fault)	SOLUTION
7	The primary blower motor overload is tripped.	Turn power off on Control panel by turning the Main Disconnect to the OFF position. Reset overload.
8	The system has shut down due to secondary blower low air flow. 	Visually examine the Secondary Blower for any obstructions that may be causing low air flow. . Check slide gate located between Secondary chamber and blower, ensure it is open. Check damper assembly, ensuring Modutrol crank arm is still connected and that butterfly damper is open, allowing air flow. Air flow switch may be defective. Refer to Section 6 of this manual. There are two ports on the air flow switch marked V and P. Ensure the inlet tube is attached to the port marked “P” for pressure. V stands for vacuum. Ensure the “V” port is open to atmosphere and is not blocked. If no air restriction is observed (i.e. blockage in the tube) change the air proving switch. Refer to Section 7 of this manual.
9	The Secondary blower variable frequency drive is faulted.	Push fault reset button on the HMI If fault persist check the error code on the variable frequency drive and check manual for troubleshooting alarm.
10	The Waste oil tank is low	This is a warning which will appear for 5 seconds if you try and start the system when solid and waste oil is selected, the system will not start. Add waste oil to the tank and the alarm should reset itself.
11	The Waste oil burner is not all the way in.	Check that the burner is all the way in. Check the limit switch arm and wiring.
12	The Waste Oil burner is not all the way out.	Check that the burner is all the way out and connecting with the limit switch. Check the limit switch arm and wiring.

ECO WASTE SOLUTIONS

MAINTENANCE INSTRUCTIONS

SUMMARY OF PREVENTIVE MAINTENANCE INSTRUCTIONS

IF APPLICABLE: The air compressor pump is shipped with break-in oil which should be changed after the first 8 hours of operation.

Daily Maintenance

Freq.	Routine	Component	Description
Daily	Inspection & Cleaning	Burners	Inspect fuel lines for leaks.
Daily	Inspection & Cleaning	Refractory	Check inside the Chambers for shrinkage or any exposed metal.

Weekly Maintenance

Routine	Component	Description
Inspection & Cleaning	Blowers and Assembly	Modutrol crank arm connected to damper.
Inspection & Cleaning	Blowers and Assembly	Slide gates are open.
Inspection & Cleaning	Burners	Secondary Burner maintenence
Inspection & Cleaning	Waste Oil Burner Filter	Clean the canister filter
Inspection & Cleaning	Air compressor	Check air filter
Inspection & Cleaning	Air compressor	Pull ring on safety valve and allow the ring to snap back to normal position (Check for free operation of the safety valve)
Inspection & Cleaning	Thermocouples	Remove and clean thermocouples as necessary – inspect for damage. Replace if necessary.

ECO WASTE SOLUTIONS

Monthly Maintenance

Routine	Component	Description
Inspection & Cleaning	Blowers and Assembly	Check the fan wheel for any wear or corrosion, as either can cause catastrophic failures
Inspection & Cleaning	Refractory	Check the refractory in the Secondary Chamber for shrinkage, anything greater than 1.2cm should be patched (i.e. gaps between modules exposing metal surface)
Inspection & Cleaning	Waste Oil	Visually check all electrical components
Inspection & Cleaning	Waste Oil	Remove heater element from casing and inspect for build-up. Clean any deposits. When reinstalling the heater element always ensure the bundle will be restarted immersed. **NEVER** use the inline oil heater dry
Inspection & Cleaning	Air compressor	Check all fasteners for proper tightness.

Quarterly Maintenance

Routine	Component	Description
Inspection & Cleaning	Blowers and Assembly	Lubricate all bearings – lubrication intervals depend on operating speed (RPM). Clean cooling fan on motors.
Inspection & Cleaning	Refractory	Inspect door gasket for damage or heat damage. Replace segments, if necessary. Doors must close tightly and securely.
Inspection & Cleaning	Refractory	Check all refractory for damage. Patch or replace as needed. Patch if modules show a little gap and replace modules if the modules have shrunk excessively (greater than 1”)
Inspection & Cleaning	Paint	Maintain paint exterior to protect metal from heat damage

Yearly Maintenance

Routine	Component	Description
Detailed Maintenance	Refractory	Replace door gasket
Inspection & Cleaning	Electrical	Check the limit switch

24 to 60 Months

.

Periodicity	Routine	Component	Description
24 Monthly	Detailed Maintenance	Refractory	Replace the door sills on Primary Chamber
24 Monthly	Detailed Maintenance	Refractory	Replace the door sills on Secondary Chamber
60 monthly	Detailed Maintenance	Refractory	Relining of Secondary Chamber.
60 monthly	Detailed Maintenance	Refractory	First stack section to be relined.
60 monthly	Detailed Maintenance	Fuel Tanks	Inspect Fuel tanks

ECO WASTE SOLUTIONS

PREVENTIVE MAINTENANCE INSTRUCTIONS

Instruction Classification

Each component is associated with an identification number, see table below:

System Component	Identification number
Primary Blower	01-001
Secondary Blower	02-001
Primary Burner	01-002
Secondary Burner	02-002
Refractory	05-001
Waste Oil Burner	02-003
Air Compressor	03-001
Main Control Panel	03-010
Paint	05-003
Electrical	05-004
Limit Switch	05-005

To differentiate if the instruction is weekly, monthly, quarterly or yearly, the above identification number will be followed by a letter:

Daily: D
Weekly: W
Monthly: M
Quarterly: Q
Yearly: Y

For example**, 01-001.Q.01** Primary blower assembly quarterly instruction number 1.

Zero Mechanical State & Lock Out Instructions

Proper maintenance of the equipment is essential to ensure long term, reliable operation of the EWS model Incinerator. The preventive maintenance instructions are outlined in this section of the Facility Manual.

NOTE

The warranty will become void if proper maintenance is not performed as instructed.

Safety

During maintenance of the EWS mobile incinerator, it is very important to be aware of special hazards. Two safety programs are described in the following sections:

1. Zero Mechanical State
2. Power Lock Out Instructions

Failure to comply with these instructions during maintenance could result in injury or death. The responsibility for implementation of a comprehensive safety program rests with the operating staff and supervision. The safety instructions in this Facility Manual should be considered only as a starting point for the safety program at site.

ACCIDENTS CAN BE PREVENTED
A CAREFUL WORKER IS THE BEST SAFETY DEVICE

Zero Mechanical State

Zero Mechanical State (ZMS) exists when the possibility of an unexpected mechanical movement has been eliminated. During maintenance, it is mandatory to totally deactivate the incinerator so that there is no possibility of an unexpected machine movement. Power lock-out, described in the next section, is commonly used for this purpose. Most machines are powered by electrical, hydraulic or pneumatic drives. Energy may be stored in a shutdown machine in various ways: Air pressure in a cylinder, hydraulic fluid stored in pressurized hoses, or machine members whose weight can generate fluid pressure. Therefore, just cutting off the electrical power may not be enough to neutralize all power sources. Certain maintenance instructions at site should require ZMS condition as a matter of course.

Zero Mechanical State (ZMS) Checklist

1. Every electrical power source to the incinerator must be cut off and locked out (to prevent others who may not be aware of maintenance work from turning the power back on inadvertently).
2. Ensure that the mechanical potential energy of the incinerator is at its lowest practical value so that opening of pipe, tubing, hose or actuation of any valve will not produce an unexpected movement that could cause injury.

3. Check that there is no pressurized fluid (air, oil, gas or other) trapped in the incinerator lines, cylinders or other components. This will ensure that there will be no incinerator motion when a valve is actuated.

4. Secure loose or freely moving parts so that there is no possibility of accidental movement.

Power Lock Out Instructions

Unexpected operation of electrical equipment started by automatic or manual remote control may cause injuries to persons who happen to be nearby. For this reason, when repair work is to be done on motors or other electrical equipment the circuit should be opened at the switch box and the switch pad locked in the OFF position. Tag the switch with a lock out tag indicating who must be contacted before the power is turned back on again.

BECAUSE OF THE SEVERE CONSEQUENCES, INCLUDING DEATH, OF NOT PROPERLY LOCKING OUT ELECTRICITY SUPPLIES DURING MAINTENANCE, THE SUPERVISOR SHOULD ENSURE THAT THERE IS ONLY 1 KEY FOR THE LOCK USED TO LOCK OUT THE POWER SUPPLY.

For identification, locks may be color coded to indicate different crews or shifts.

The Supervisor should maintain the master key and list of key numbers, and should keep an extra key to each lock for his department. The master key should not be loaned out under any circumstances.

No matter what method is used to lock out power, strict discipline and constant supervision should be employed during any equipment maintenance work.

Power Lock Out Checklist

1. Alert the operator of the equipment.

2. Before starting the work on an engine, motor, line shaft or other power transmission equipment or power-driven machine, make sure it cannot be set in motion without your knowledge.

3. Place your own padlock on the control switch, lever, or valve, even if someone has locked the control panel before you. You will not be protected unless you put your own padlock on it. (Another maintenance person could remove their lock and then someone else could start the equipment if they were not aware of maintenance work being done.)

When you are finished working, remove your own padlock. Never permit someone else to remove it for you. Be sure you are not exposing someone else to danger by removing your padlock

Daily Instructions

Primary & Secondary Chamber Burners: (01-002.D & 02-002.D)

Do not store flammable or hazardous materials in the vicinity of fuel burning appliances.

Improper installation, adjustment, alteration, service or maintenance can cause property damage, personal injury or death.

Burner shall be installed and maintained in accordance with manufacturer's requirements as outlined in the Burner manual, local codes and authorities having jurisdiction.

INSTRUCTION 01/02-002.D.02: INSPECTING THE FUEL LINES

1. Visually inspect all fuel lines to the Primary and Secondary Burner as well as to the Waste Oil burner for any leaks.

2. If any leaks are observed tighten or replace the piping section where the leak is occurring

Refractory: (05-001.D)

When working with the refractory make sure you use the proper tools; wear goggles, approved dust mask and gloves

INSTRUCTION 05-001.D.01: INSPECTING THE REFRACTORY

Ensure power is locked out.

Please follow all instructions outlined in *Zero Mechanical State & Lock Out Instructions.*

1. Open Primary Chamber door by unlatching all clamps.

2. Tie-off door to open position to ensure that it will not close unintentionally.

3. Enter Primary Chamber and check the refractory for shrinkage, any gap between the modules greater than 2.5 cm should be patched with the blanket refractory

4. Check for any exposed metal between the modules, if metal is exposed make sure to patch area with blanket material (PN: 501803) or new module (PN: 433026) (*CMI 4.4.2/05-001A & 4.4.2/05-001B)*Weekly Instructions

Primary & Secondary Chamber Blowers: (01-001.W & 02-001.W)

Do not attempt any maintenance on a fan unless the electrical supply has been completely disconnected and locked.

Please follow all instructions outlined in *Zero Mechanical State & Lock Out Instructions.*

A fan can windmill despite removal of all electrical power therefore, take extra care when working with fans in the system.

The rotating assembly should be blocked securely before attempting maintenance of any kind.

INSTRUCTION 01/02-001.W.01: DAMPER CRANK ARM

Check to see that the damper crank arm is connected to the damper and the rod.

Ensure mechanical linkage on damper is tight, if loose tighten with wrench.

PRIMARY BLOWER

1. Air Proving Switch
2. Modutrol Motor
3. Motor Crank Arm
4. Damper Crank Arm
5. Rod
6. Damper

ECO WASTE SOLUTIONS

SECONDARY BLOWER

1. Air Proving Switch
2. Modutrol Motor
3. Motor Crank Arm
4. Damper Crank Arm
5. Rod
6. Damper

A. Damper Crank arm and connection to Damper and Rod

INSTRUCTION 01/02-001.W.02: SLIDE GATES

Check to see if slide gates move freely.

1. Move slide gate in and out to ensure free movement. If sticking, use lubricant to loosen. Lubricant should be rated for a high temperature (>150°F) application.

2. Gates must be opened to allow under fire air to enter the chamber. They should only be closed to reduce air in abnormal operating conditions.

1. Sample Primary Chamber Slide Gate Open

2. Sample Primary Chamber Slide Gate Closed

3. Sample Secondary Chamber Slide gate Open

Primary & Secondary Chamber Burners: (01-002.W & 02-002.W)

Do not store flammable or hazardous materials in the vicinity of fuel burning appliances.

Improper installation, adjustment, alteration, service or maintenance can cause property damage, personal injury or death.

Burner shall be installed and maintained in accordance with manufacturer's requirements as outlined in the Burner manual, local codes and authorities having jurisdiction.

Switch off the electrical power. Please follow all instructions outlined in *Zero Mechanical State & Lock Out Instructions.* Cover must be removed to perform maintenance on burners.

ECO WASTE SOLUTIONS

INSTRUCTION 01/02-002.W.02: PRIMARY & SECONDARY BURNER MAINTENENCE

Refer to Burners manuals in section 8 of this manual

Primary Burner: Riello 40 Model G900
Secondary Burner: Riello RS 38/M

Air Compressor: (03-001.W)

INTAKE AIR. Can contain carbon monoxide or other contaminants. Will cause serious injury or death. This air compressor is not designed, intended or approved for breathing air. Compressed air should not be used for breathing air application.

HAZARDOUS VOLTAGE. Can cause serious injury or death. Disconnect power and bleed pressure from the tank before servicing.

MOVING PARTS. Can cause serious injury. Do not operate with guards removed. Machine may start automatically. Disconnect power before servicing.

HOT SURFACES. Can cause serious injury. Do not touch. Allow to cool before servicing. Do not touch hot compressor or tubing.

HIGH PRESSURE AIR. Bypassing, modifying or removing safety/relief valves can cause serious injury or death. Do not bypass, modify or remove safety/relief valves. Do not direct the air stream at body. Rusted tanks can cause explosion and severe injury or death. Drain tank before each use. Drain valve located at bottom of tank.

RISK OF BURSTING. Use only suitable air handling parts acceptable for pressure of not less than the maximum allowable working pressure of the machine.

INSTRUCTION 03-001.W.02: INSPECTING AIR FILTERS IN AIR COMPRESSOR

Refer to Dewalt Compressor manual Model D55168 in section 8 of this manual

INSTRUCTION 03-001.W.03: CLEANING COMPRESSOR & CHECKING SAFETY VALVE

Cleaning

A dirty compressor will cause abnormally high temperature and result in oil carbonization on valve components.

Clean all external parts of the compressor with compressed air. Concentrate the cleaning on the external fins where dirt can accumulate as cooling air is forced across them.

Refer to Dewalt Compressor manual Model D55168 in section 8 of this manual for:

Checking Safety Valve
Draning Air Tank

Thermocouple: (05-002.W)

When working with electrical components, ensure lock out instructions are being followed.

Thermocouple Assembly

Thermocouple Element

ECO WASTE SOLUTIONS

INSTRUCTION 05-002.W.01: INSPECT THERMOCOUPLE FOR DAMAGE

Turn main power to the system off - Remove thermocouple and visually inspect for damage. If damaged, see *CMI 4.4.1/05-002A*

1. Secondary Thermocouple (TC2) on Secondary Chamber Container
2. Primary Thermocouple (TC1)
3. Stack Thermocouple (TC3) not shown

ECO WASTE SOLUTIONS

Monthly Instructions

Primary & Secondary Chamber Blowers: (01-001.M & 02-001.M)

Do not attempt any maintenance on a fan unless the electrical supply has been completely disconnected and locked. In many cases, a fan can windmill despite removal of all electrical power. The rotating assembly should be blocked securely before attempting maintenance of any kind.

Please follow all instructions outlined in *Zero Mechanical State & Lock Out Instructions.*

INSTRUCTION 01/02-001.M.01: CHECK FAN WHEEL

1. Check the fan wheel for any wear or corrosion, as either can cause catastrophic failures, if left in operation.
2. The wheel can be accessed one of two ways.
   a. Remove the blower assembly from the unit and look down the outlet of the blower.
   b. Remove the damper assembly from the inlet of the blower and inspect by looking through the inlet of the blower.
3. Check also for the build-up of material which can cause unbalance resulting in vibration, bearing wear and serious safety hazards.
4. Clean the wheel as required.
5. If replacement is necessary follow these steps:
   a. Remove damper assembly from the unit
   b. Remove the blower assembly
   c. Remove the blower housing around the wheel
   d. Loosen all set screws that are located on the wheel.
   e. A puller may be required if the wheel hasn't been removed for some time.
   f. Ensure the shaft "key" is installed on the shaft before installing the new wheel.
   g. When installing a new wheel, the wheel should be positioned in the housing with the correct spacing between the edge of the inlet cone and the wheel. The wheel to cone clearance on the Primary Blower is 0.3175 cm.
   h. Ensure that the wheel is installed securely before reassembling the blower assembly.
   i. Install the blower assembly
   j. Install the damper assembly

ECO WASTE SOLUTIONS

INSTRUCTION 05-001.M.01: INSPECT REFRACTORY

1. Ensure power is locked out.
2. Open Primary Chamber door.
3. Fasten door open, ensuring it will not close by its own weight.
4. Enter Primary Chamber and check the refractory for shrinkage, any gaps between the modules greater than 2.5 cm should be patched.
5. Fix gaps with supplied blanket by stuffing material into opening. (See *CMI 4.4.2/05-001A)*
6. Check for any exposed metal, if metal is exposed make sure to patch area with blanket material or new module. (See *CMI 4.4.2/05-001A* & *4.4.2/05-001B)*
7. Pay special attention to areas where the junction boxes are located, as any excessive heat may melt the wires within the box.
8. While inside the Primary Chamber using a flashlight check the status of the Dome and the center piece which consist of 3 holes.

Some cracking is normal, however if pieces are missing or have fallen out, (See *CMI 4.4.2/05-001E)*

Waste Oil Burner: (02-003.M)

Failure to maintain and / or improper servicing by unqualified personnel will adversely affect the proper, safe operation of your burner, will reduce the service life of your burner and will void your warranty

INSTRUCTION 02-003.M.01: INSPECT ELECTRICAL COMPONENTS

1. Check all electrical components for any heat damage.
2. If heat damage is observed remove and replace.

ECO WASTE SOLUTIONS

1. Slide out burner
2. Undo Bolt

3. Loosen Bolt

4. Open hinged hatch to access front components

INSTRUCTION 02-003.M.02: INSPECT HEATER ELEMENT

1. Remove heater element from casing and inspect for build-up

2. Clean any deposits.

3. If damaged, heater element needs to be replaced. Removal involves the following steps:
    a. Remove all electrical connections attached to the heater block identified in Picture #3 below.
    b. Remove all the bolts attaching the heater to the burner housing.
    c. Remove all fuel line connections.

d. Remove the heater element and install the new one. (PN: 33173)
e. Reinstall the heater block.

4. When reinstalling the heater element always ensure the element will be restarted immersed.

NEVER use the inline heater dry

1. Unscrew (yellow) electrical connection

2. Remove cover screw

3. Open hatch cover to expose heater element

Air Compressor: (03-001.M)

INTAKE AIR. Can contain carbon monoxide or other contaminants. Will cause serious injury or death. This air compressor is not designed, intended or approved for

breathing air. Compressed air should not be used for breathing air application unless treated in accordance with all applicable codes and regulations.

HAZARDOUS VOLTAGE. Can cause serious injury or death. Disconnect power and bleed pressure from the tank before servicing. Compressor must be connected to properly grounded circuit. Do not operate compressor in wet conditions. Store indoors.

MOVING PARTS. Can cause serious injury. Do not operate with guards removed. Machine may start automatically. Disconnect power before servicing. Lockout/Tagout machine.

HOT SURFACES. Can cause serious injury. Do not touch. Allow to cool before servicing.

HIGH PRESSURE AIR. Bypassing, modifying or removing safety/relief valves can cause serious injury or death. Do not bypass, modify or remove safety/relief valves. Do not direct air-stream at body. Rusted tanks can cause explosion and severe injury or death. Drain tank before each use. Drain valve located at bottom of tank.

RISK OF BURSTING. Use only suitable air handling parts acceptable for pressure of not less than the maximum allowable working pressure of the machine.

INSTRUCTION 03-001.M.01: CHECK FASTENERS FOR TIGHTNESS

1. Check all fasteners for tightness (tighten as required).

2. Check the safety valve manually, by pulling ring or lever, to make sure that it is not stuck. Allow the ring to snap back to normal position

Quarterly Instructions

Primary & Secondary Chamber Blowers: (01-001.Q & 02-001.Q)

Do not attempt any maintenance on a fan unless the electrical supply has been completely disconnected and locked. In many cases, a fan can windmill despite removal of all electrical power. The rotating assembly should be blocked securely before attempting maintenance of any kind.

Please follow all instructions outlined in *Zero Mechanical State & Lock Out Instructions.*

INSTRUCTION 01/02-001.Q.01: LUBRICATE BEARINGS

1. Lubricate the bearings, but do not over lubricate.

2. Bearings are completely filled with grease at the factory; they may run at an elevated temperature during initial operation. Surface temperatures may reach 180°F and grease may bleed from the bearing seals. This is normal and no attempt should be made to replace lost grease. Bearing surface temperatures will decrease when the internal grease quantity reaches a normal operating level.

3. Bearings should be lubricated with premium quality lithium-based grease conforming to NLGI Grade 2. Examples are:

   Mobil - Mobilgrease XHP
   Texaco - Premium RB
   Chevron - Amolith #2
   Shell - Alvania #2

4. Add grease to the bearing via the grease nipple while running the fan or rotating the shaft by hand. Be sure all guards are in place if lubrication is performed while the fan is operating. Add just enough grease to cause a slight purging at the seals. Do not over lubricate.

1. Sample Secondary Blower Cover

1. Sample Grease Nipples

Refractory: (05-001.Q)

When working with the refractory make sure you use the proper tools; wear goggles, dust mask and gloves

Please follow all instructions outlined in *Zero Mechanical State & Lock Out Instructions.*

INSTRUCTION 05-001.Q.01: INSPECT DOOR GASKETS

1. Open Primary Chamber door.
2. Fasten door open, ensuring the door will not close on its own.
3. Inspect door gasket for damage.
4. Replace any damaged segments of door gasket (PN: 462007) if necessary. Cut out the damaged section and replace with new door gasket. See *CMI 4.4.2/05-001C*.
5. Doors must close tightly and securely, ensuring a good seal.

Sample Primary Door (refractory lined)

1. Primary Door Gasket

ECO WASTE SOLUTIONS

INSTRUCTION 05-001.Q.02: INSPECT REFRACTORY FOR SHRINKAGE

1. Ensure power is locked out.
2. Open Primary Chamber door.
3. Fasten door open, ensuring they will not close on their own.
4. Enter Primary Chamber and check the refractory for shrinkage, anything greater than 2.54 cm should be patched.
5. Check to make sure the anchoring of the modules is still strong and intact, if any modules seem loose replace complete module with new module.

A. REMOVAL: Remove existing Module (physically pull away existing refractory from underlying Module Anchor).

B. Remove welded stud from steel casing (cut with hack saw or other device between Module Anchor and Furnace Casing/Shell).

Figure 1: Side view of the Weld Loc Module

Figure 2: Stud Gun with rasp and Torque Tube.

A. INSTALLATION: Once the new module (PN: 433026) is in place take the stud gun (PN: ECO-STUD) with rasp to the Torque Tube and drill into place.

B. Once it has tightened the Torque Tube should come off with the drill.

ECO WASTE SOLUTIONS

Paint: (05-003.Q)

Ensure proper ventilation and proper equipment is being used when using any paint product.

INSTRUCTION 05-003.Q.01: INSPECT AND MAINTAIN EXTERIOR PAINT

1. Maintain paint exterior to protect metal from heat and corrosion damage. This includes all components in the system including containers and incinerator components.

2. If discoloration is noted and painting needs to be performed, on areas where paint will be applied, you must do a light sanding before application.

3. Follow paint manufacturer's application instructions which will include surface preparation, priming and painting.

Paint Specifications:

Incinerator Paint: This is the paint coated directly on the incinerator shell. This includes the following components:

1. Primary Chamber
2. Secondary Chamber
3. Hot Stack Section (Black)

Finish needs to be able to withstand temperatures in the 650-750°F (340-400°C) range.

Parts: There are no paint specifications for each individual component. This is left up to the discretion of the customer.

Yearly Instructions

Refractory: (05-001.Y)

When working with the refractory make sure you use the proper tools; wear goggles, dust mask and gloves

INSTRUCTION 05-001.Y.01:
CHECK DOOR GASKET ALONG PRIMARY CHAMBER DOOR

1. If required replace the door gasket. The gasket can last over 2 years but will depend on the careful use by the operator when loading and unloading.

2. Remove the damaged section of door gasket from door and reinstall new gasket (PN: 462007)

Sample Primary Door (refractory lined)

Primary Door Gasket

Electrical: (05-004.Y)

When working with electrical components ensure lock out instructions are being followed

Please follow all instructions outlined in *Zero Mechanical State & Lock Out Instructions.*

ECO WASTE SOLUTIONS

INSTRUCTION 05-004.Y.01: CHECK LIMIT SWITCHES

NOTA System must not be running or in cool down to perform this inspection.

1. Open Primary Chamber door and check top view screen on the HMI Panel view to ensure that it indicates door is open.

2. Close Primary Chamber door and check top view screen on the HMI Panel View to ensure that it indicates door is closed.

3. All limit switches located on the unit are checked this way.

4. Replace limit switches (PN: 802T-APE) if necessary.

Primary Chamber Limit Switch

Waste Oil Burner Out Limit Switch

Waste Oil Burner In Limit Switch

Waste Oil Burner In Limit Switch

Waste Oil Burner Out Limit Switch

Waste Oil Burner: (02-003.Y)

Failure to maintain and / or improper servicing by unqualified personnel will adversely affect the proper, safe operation of your burner, will reduce the service life of your burner and will void your warranty

INSTRUCTION 02-003.Y.01: SERVICING THE METERING PUMP

1. Remove the pump head cover.
2. Remove the screen and wash it.
3. Remove and discard the used gasket.
4. Install a new gasket.
5. Replace the screen and pump head cover.

For more detail, refer to OEM Waste Oil Burner Manual

Corrective Maintenance Instructions (CMI)

The following instructions relate to the replacement or correction (fixing) of components of the EWS Mobile Incinerator Package.

These Corrective Instructions are grouped in this section by the following:

4.4.1 General Corrective Maintenance Instructions
4.4.2 Refractory Corrective Maintenance Instructions
4.4.3 Primary & Secondary Burner Corrective Maintenance Instructions
4.4.4 Primary & Secondary Blower Corrective Maintenance Instructions
4.4.5 Waste Oil Burner Corrective Maintenance Instructions
4.4.6 Main Control Panel Corrective Maintenance Instructions

As per the *Preventive Maintenance Instructions Manual*, the following table is utilized to identify the components of the system that require corrective maintenance.

System Component		**Identification number**	
Primary Burner		**01-002**	
	Replacing Fuel Filter		4.4.1/01-002A
Secondary Burner		**02-002**	
	Replacing Fuel Filter		4.4.1/02-002A
Thermocouple		**05-002**	
	Replacing Thermocouple		4.4.1/05-002A
Limit Switch		**05-005**	
	Limit Switch Replacement		4.4.1/05-005A
Refractory		**05-001**	
	Wall Refractory: Gaps between the Modules		4.4.2/05-001A
	Wall Refractory: Replacement of the Modules		4.4.2/05-001B
	Door Gasket		4.4.2/05-001C
	Castable Refractory		4.4.2/05-001D
	Temporary Repair of Castable		4.4.2/05-001E
Primary Blower		**01-001**	
	Air Proving Switch Replacement		4.4.4/01-001A
	Damper Calibration		4.4.4/01-001B
	Modutrol Resistor Replacement		4.4.4/01-001C
	Damper Crank Arm Replacement		4.4.4/01-001D
	Motor Replacement		4.4.4/01-001E
	Modutrol Motor & Transformer Replacement		4.4.4/01-001F
Secondary Blower		**02-001**	
	Air Proving Switch Replacement		4.4.4/02-001A
	Damper Calibration		4.4.4/02-001B
	Modutrol Resistor Replacement		4.4.4/02-001C
	Damper Crank Arm Replacement		4.4.4/02-001D
	Motor Replacement		4.4.4/02-001E
	Modutrol Motor & Transformer Replacement		4.4.4/02-001F
Waste Oil Burner		**02-003**	
	Waste Oil Burner		4.4.5/02-003A
	Waste Oil Burner Parts Replacement		4.4.5/02-003B

	Waste Oil Burner J-Pump Replacement		4.4.5/02-003C
Main Control Panel		**03-010**	
	Main Control Panel		4.4.6/03-010A
	Reboot PLC		4.4.6/03-010B

General Corrective Maintenance Instructions

LIMIT SWITCH REPLACEMENT (4.4.1/05-005A)

1. Loosen the 2 screws holding the limit switch in place.
2. Remove limit switch, replace with a new one (PN: 802T-APE).
3. Take arm off of old body and mount to new.
4. Tighten the 2 screws holding the limit switch body.

REPLACING THERMOCOUPLE (4.4.1/05-002A)

The thermocouple will require routine replacement. The environment inside the incinerator will erode the protection tube to the point of failure. If the element is exposed to this environment it will be destroyed and will need to be replaced.

1. Unscrew thermocouple lid and remove wires.
2. Remove protection tube. To aid with this a vise and a pipe wrench will be needed.
3. Remove element and replace with new element (PN: TK-K08B-0100-S) and protection tube (PN: TA-A427A-K08B-010).

4. Reinstall on incinerator.

5. After installation turn power back on. Observe the temperature reading of the thermocouple you were just working on. If the wires were installed incorrectly the temperature will read the opposite temperature. (I.e. 20°C would read as -20°C). If this is the case open the thermocouple housing and switch the wires.

Refractory Corrective Maintenance Instructions

When working with the refractory make sure you use the proper tools; wear goggles, dust mask and gloves

WALL REFRACTORY: GAPS BETWEEN THE MODULES (4.4.2/05-001A)

The ceramic block refractory will shrink over time exposing the exterior metal shell. These gaps need to be filled in with ceramic refractory blanket.

1. Identify gaps in the chamber that are larger than 1” in width between the modules or if you can see exterior shell.

2. With a Utility knife cut a length of ceramic blanket (PN: 501803) that will fit in the gap between the modules.

3. Stuff the blanket into the space with a straight edge or ruler.

WALL REFRACTORY: REPLACEMENT OF MODULES (4.4.2/05-001B)

Excessive damage to a section of refractory may necessitate the replacement of modules in the incinerator. Such damage is largely due to mechanical wear. The following diagram walks through the removal and installation of new modules.

A. REMOVAL: Remove existing Module (physically pull away existing refractory from underlying Module Anchor)

B. Remove welded stud from steel casing (cut with hack saw or other device between Module Anchor and Furnace Casing/Shell)

Figure 1: Side view of the Weld Loc Module

Figure 2: Stud Gun with rasp and Torque Tube (part of module assembly).

C. INSTALLATION: Once the new module is in place take the stud gun with rasp to the Torque Tube and drill into place.

D. Once it has tightened the Torque Tube should come off with the drill.

DOOR GASKET REFRACTORY (4.4.2/05-001C)

The door gasket will degrade over time and will need to be replaced. The bottom of the door will see more degradation due to the waste burning in that vicinity.

1. Identify the damaged section of gasket that will need to be removed
2. With a utility knife cut out the section that needs to be replaced.
3. A new piece of gasket (PN: 462007) will need to be cut the same length as the removed piece.
4. With contact cement coat the gasket on one side and the door section and install.

CASTABLE REFRACTORY (4.4.2/05-001D)

Operators will notice that the castable refractory will show signs of minor cracking. The minor cracking is normal. Large sections of castable should not separate from the rest of the monolithic cast. Such occurrences are largely due to a sudden impact from machinery or dropping of the units themselves. Mortar is supplied to help with a temporary repair while a permanent repair is resolved.

TEMPORARY REPAIR OF CASTABLE (4.4.2/05-001E)

1. Find the pieces of castable refractory that have separated.
2. Clean both the pieces of refractory and the area where the separation occurred.
3. Spread an even amount of high temperature mortar (PN: 452036) on the pieces and the area of separation.
4. Put the pieces back where they originated and support as necessary for a minimum of an hour while the mortar cures.

LEVEL SWITCH REPLACEMENT (4.4.3/01-002G & 02-002G)

The level switch is located in the Waste Oil Tanks.

NOTE

Tank does not have to be emptied to replace.

1. Unplug the level switch.
2. Disconnect the cord and remove the level switch.
3. Replace level switch (PN: FS301-01) and reconnect the cord.
4. Plug in the level switch.

Primary & Secondary Blower Corrective Maintenance Instructions

Do not attempt any maintenance on a fan unless the electrical supply has been completely disconnected and locked. In many cases, a fan can windmill despite removal of all electrical power. The rotating assembly should be blocked securely before attempting maintenance of any kind.

Primary Blower Assemblies are not a commonly repaired part on the incinerator. Parts within this assembly will need to be repaired or replaced. They are outlined below.

Primary Blower

1. Air Proving Switch
2. Modutrol Motor
3. Motor Crank Arm
4. Damper Crank Arm
5. Rod
6. Damper

Secondary Blower Assemblies are not a commonly repaired part on the incinerator. Parts within this assembly will need to be repaired or replaced. They are outlined below.

Secondary Blower

1. Air Proving Switch
2. Modutrol Motor
3. Motor Crank Arm
4. Damper Crank Arm
5. Rod
6. Damper

AIR PROVING SWITCH REPLACEMENT (4.4.4/01-001A & 02-001A)

1. Ensure all power is locked out.
2. Remove wiring from switch.
3. Remove tubing from switch.
4. Unscrew screws at the two locations and remove switch.
5. Reinstall new switch (PN: SML8221210034) complete with tubing and wiring and then retighten.
6. Turn power back on.

DAMPER CALIBRATION (4.4.4/01-001B & 02-001B)

Sometimes the damper linkage will slip when the connections become loose (Items 3,4,5 in the Secondary Blower photo) In order to ensure that the linkage is correctly calibrated the operator will need to look at the display screen on the control panel while the unit is in operation

1. Read the %Open value on the control panel operator interface for the Primary Blower.
2. During operation the damper is factory preset to be 0% open, or fully closed.
3. Look inside the damper (Item 6) and ensure that the linkage is completely closed.
4. If it is, then this maintenance is complete.
5. Should the damper be open even a small percentage the linkages are to be loosened and the damper adjusted to be completely closed, and then retighten.

MODUTROL RESISTOR REPLACEMENT (4.4.4/01-001C & 02-001C)

The Modutrol resistors are located inside the top lid of the Modutrol motor. Remove the lid to the Modutrol motor by unscrewing the top four (4) screws. The connection between the control panel and the Modutrol is made with a small white connector with 3 terminals. Jumpered between these terminals is the resistors.

Remove and replace the resistors one at a time to ensure the correct resistors are replaced. You identify the correct resistor by examining the color band on the center node of the resistor. Replace like resistors.

DAMPER CRANK ARM REPLACEMENT (4.4.4/01-001D & 02-001D)

The crank arm will only need to be replaced if the arm is damaged due to misuse. Identify the damper crank arm (Item #4 in the picture on the previous page).

Identify the location of the linkage on the rod and the damper arm with a marker, so the new crank arm will be in the same spot when reinstalled. Remove the connections to the crank arm and replace with the new one (PN: 26026G) and ensure it is in the same spot as the old one.

MOTOR REPLACEMENT (4.4.4/01-001E & 02-001E)

Information on replacing the motor can be found in the OEM manual New York Blower, Installation, Maintenance and Operating, IM-160 Junior Fans.

MODUTROL MOTOR & TRANSFORMER REPLACEMENT (4.4.4/01-001F & 02-001F)

To replace the Modutrol motor all power to the system need to be off as you will need to expose electrical connections. First get the new motor and orientate the motor in the same direction as the old motor. Identify where the conduit is connected on the old motor and punch the connector holes for the new motor.

Removal

1. Remove all electrical terminations and remove the transformer.
2. Install the transformer in the new Modutrol motor.
3. Remove all conduit connections on the motor.
4. Remove the damper arm and linkage from the motor.
5. Unbolt the motor from the damper, and ensure all nuts and bolts are kept for the new motor install

Install

1. Bolt the new motor in the same orientation as the old motor.
2. Install the damper arm and linkage to the motor
3. Install all conduit connections

Terminate all electrical connections the same as the old motor.

REPLACE THE BLOWER CONTACTOR 4.4.4/01-001G

1. Turn Main Disconnect Switch into the OFF position.
2. Open Panel.
3. Remove the wires.
4. Pull the retaining clip up.
5. Tilt contactor forward and remove.
6. To reinstall tilt new contactor until it clicks back in.
7. Pull the retaining clip back down to lock.
8. Reinstall wires.
9. Close panel.
10. Turn power back on.

Waste Oil Burner Corrective Maintenance Instructions

Failure to maintain and/or improper servicing by unqualified personnel will adversely affect the efficient and safe operation of your burner, will reduce the service life and will void your warranty.

WASTE OIL BURNER HEATER ELEMENT CLEANING / REPLACEMENT (4.4.5/02-003A)

Slide out burner undo bolt

Loosen hinge hatch bolt

Open hinged hatch to access front components

Unscrew (yellow) electrical connection

Remove Cover Screw

Open hatch cover to expose heater element

Remove heater element from casing and inspect for build-up.

Clean any deposits.

When reinstalling the heater element (PN: 33173) always ensure the element will be restarted immersed in waste oil. A dry element while in operation will reduce the life of the element.

WASTE OIL BURNER PARTS REPLACEMENT (4.4.5/02-003B)

The waste oil burner has the following parts that may need replacing:

Part Description	Part #	Description of replacement
Primary Control	33391	Locate remove and reinstall new one
Igniters Transformer	33189	Locate remove and reinstall new one
CAD Cell	33116	Locate remove and reinstall new one
Fan Squirrel Cage	31113	Locate remove and reinstall new one
Blower Motor	33337	Locate remove and reinstall new one
Retention Head	11427	Locate remove and reinstall new one
Air Pressure switch	33057	Locate remove and reinstall new one
Heater Block	26090	Locate remove and reinstall new one
Air / Oil Solenoid	32322	Locate remove and reinstall new one

WASTE OIL BURNER J-PUMP REPLACEMENT (4.4.5/02-003C)

Waste Oil Burner Pump (J-Pump) Sample location

Removing the pump requires the power to be off to the system. When this is done complete the following step:

1. Open the junction box on the side of the motor of the pump. Disconnect the electrical connections and remove the conduit connection
2. With fuel containment cloth remove the waste oil connection from the pump inlet and outlet.
3. Unbolt the pump. Remove from the chamber

Install the new pump by reversing the above steps.

MAIN CONTROL PANEL (4.4.6/03-010A)

All control panel diagnostics are to be completed by certified or trained technicians. Electrical drawings / diagrams are provided to aid electricians with any diagnostics.

REBOOT PLC (4.4.6/03-010B)

Turn Main Disconnect to the off position on the front of the Control Panel. Turn the main disconnect back on.

Acronyms and Abbreviations

The following acronyms and abbreviations are used throughout this Subsidence Monitoring and Management Plan.

SMMP	Subsidence Monitoring and Management Plan
VOK	Valley of the Kings
LiDAR	Light detection and ranging
AMP	Adaptive Management Plan
UAV	Unmanned Areal Vehicles
InSAR	Interferometric Synthetic Aperture Radar
WZ	West Zone
BZ	Bridge Zone
WRD	Waste Rock Dump

1 Introduction

1.1 Purpose

Pretium Resources Inc. (Pretivm) – now NCM (Newcrest Mining) Brucejack, retained SRK Consulting (Canada) Inc. (SRK) to prepare a Subsidence Monitoring and Management Plan (referenced here in as the SMMP or the Plan) for Brucejack Mine as per *Mines Act* Permit M-243 Condition D.13.

The enclosed SMMP has evaluated the effectiveness of subsidence controls to provide an early warning of surface expression that may result in changes to terrestrial or aquatic values. Subsequently, this plan includes adaptive management measures for monitoring subsidence and developing mitigation measures as needed.

1.2 Mining Method Overview

The underground mine comprises of several ore zones: Valley of the Kings (VOK) zone, the West zone (WZ) , Bridge Zone (BZ) , Fault Zone (FZ) , Galena Hill (GH) and Office Porphyry (OFP) . The mine began commercial operation in July 2017 with production from the VOK zone. There has been no production to date in the West zone. The FZ and OFP are new zones that commenced mining in 2020. GH is on track for production in mid-year 2023. The mining method at Brucejack is long-hole stoping; a combination of longitudinal and transverse mining is used depending on the width and orientation of the mineralized zones. The mine employs an overhand primary/secondary stoping method with cemented tailings pastefill used to backfill stopes after mining.

Predominantly, the underground development at Brucejack measures 5.5 m wide by 5.5 m high, with an increase in height to 6 m on the main ramp and crossover drives. In ore development, crosscuts are 5 m wide and 5 m high. Where stopes are to be mined, the undercut is sometimes slashed out to a total width of 15 m.

Underground developments are supported by installation of cable bolts in the upper stopes to reinforce the crown pillar and backfilling with waste rock and cemented tailings backfill upon completion. These supported mining methods have a reduced subsidence impact when compared with alternative unsupported methods.

Brucejack Mine's current permitted production rate is 3,800 tonnes per day and the mine has an anticipated mine life of 14 years.

Figure 1-1: Plan View (top) and Oblique View looking West (bottom) of the VOK/ GH/ WZ/ FZ

1.3 Geology Overview

The Brucejack gold-silver deposit is located in the Sulphurets gold-silver-copper mining camp. The deposit is interpreted as a deformed porphyry-related gold-silver epithermal deposit. High-grade gold-silver mineralization occurs as coarse aggregates of electrum and silver sulfosalts that are hosted in steeply dipping and predominantly west to northwest-trending quartz-carbonate vein stockwork and breccia zones within a broader halo of clay alteration and low-grade mineralization.

Mineralized veins and stockwork zones appear to have utilized lithological contacts and pre-existing structures. Epithermal veins are largely discordant to the penetrative foliation of the altered host rock, suggesting that mineralization postdates a fabric-forming event. Mineralized zones were tilted, thrusted, and sheared during Cretaceous compressional deformation.

The Brucejack Ground Control Management Plan (GCMP) classifies the rock mass into a number of “geotechnical units” based on characterization of the rock mass and the presence of major geological structures (Pretivm, 2020).

The geotechnical units in the VOK zone, described in BGC’s review of underground geotechnical units (BGC, 2019), are listed in order of increasing competence:

- The weathered zone comprises near-surface rocks.
- The Fault Zone unit comprises rock identified as fault-disturbed rock. It is strong, with good RQD values (75% - 90%) and close discontinuity spacing.
- Rock mass Domain 1 includes the Volcano-sedimentary Facies (argillite portion) geological unit; it very strong, with good RQD values, and moderate discontinuity spacing.
- Rock mass Domain 2 includes the Bridge Zone Porphyry, Office Porphyry, and Silicified Rock geological units; these are strong, with excellent RQD values (>90%), and moderate discontinuity spacing.
- Rock mass Domain 3 includes the Volcaniclastics, Volcano-sedimentary Facies (sandstone-conglomerate portion), S3-Trans, and ANDX units; these are strong, with excellent RQD values, and wide discontinuity spacing.

1.4 Subsidence Mechanisms Overview

Subsidence is an inevitable consequence of the extraction of minerals, liquid, or gas from beneath the ground surface. The surface expression may be of a small magnitude and localized or extend over large areas. Subsidence may occur immediately with mining or may be delayed by many years. Geology and mining methods are the main variables that dictate the magnitude of impact of subsidence and cannot be ignored.

The study of mining induced subsidence has predominantly been in connection with the mining of extensive tabular mineral deposits, such as coal and potash, through either longwall or room and pillar mining.

The effects of subsidence are not limited to the vertical displacement of the ground surface but include the total of all surface effects that are associated with the extraction of minerals. There are essentially three potential surface subsidence effects of underground mining:

- **Trough subsidence** – generally associated with the extraction of relatively flat tabular orebodies. The ground disturbance associated with the trough is generally greater than the extent of the underground workings. Cracks or fissures may be formed at the edges of the subsidence trough and reflect tensile or shear stresses in the ground surface. This is considered to be unlikely at Brucejack Mine.
- **Collapse subsidence** – caused by the failure of the strata between the underground excavations and the ground surface. The ground disturbance associated with collapse type subsidence can vary in magnitude from a zone around an individual stope (i.e., chimney subsidence) to large areas of a mine (i.e., plug failure). Collapse type subsidence generally exhibits at surface as a sinkhole or conical depression. Cracks or fissures may be formed around the depression or sinkhole. The supported mining method employed at Brucejack Mine means that this is unlikely to occur.

- **Plug failure** – generally controlled by weak, continuous geological structures in the overlying rock mass or can be initiated by the large-scale failure of pillars, either rock or backfill pillars or a combination of both. Plug subsidence is generally controlled by one or more major structural features, such as a fault or dyke, which provides a continuous plane of weakness or where the shear strength of the rock mass is overcome at a critical stage of mining or through the failure of regional mine support such as pillars or backfill. Structural geology studies conducted on the Brucejack deposit have not identified continuous features that might act as the failure surfaces for a plug type failure.

BGC Engineering Inc. completed a preliminary assessment of the potential for subsidence at the Brucejack Mine site considering the subsidence failure mechanisms listed above. This report is attached in Appendix A.

2023 Update:

SRK was consulted in 2020 to provide a second opinion on BGC's findings (Appendix B) . It was found that BGC's approach was based of analytical, empirical, and numerical analysis. SRK supplemented this with the Betournay method, which examines the likelihood of progressive UG failure. The worst-case scenario where a caving failure ceases is because of caved material occupying available void. This is related to stope dimensions, unfilled volume, and bulking factor of overlying rock mass.

The current 2022 GCMP recommends a 15m crown pillar consisting of competent rock and 10m stope strike length. Even if the stopes cannot be tight filled and a 5m unfilled gap was left in the stopes, the maximum self-mining height is also estimated at about 5m, likely due to bulking factors. This is roughly a third of the crown pillar recommended and no ground disturbance should be noticeable. The crown pillar may also be increased to 20-25m for initial stopes until stope performance (Cavity monitoring scans) are performed to monitor overbreak and back failure.

2 Subsidence Monitoring Plan

The topography, mountainous terrain, and seasonal snow and ice cover at the Brucejack Mine pose unique challenges to the development of an appropriate subsidence monitoring plan as the surfaces being monitored for subsidence are under snow cover for extended periods of the year. Furthermore, the supported mining methods employed underground, discussed in Section 1.2, drastically reduce the magnitude of subsidence effects below the level of detection without the use of precision levelling survey techniques.

Subsidence monitoring plans typically include combinations of:

- Ground-based precision surveys
- Visual observations
- Aerial and satellite photogrammetry and LiDAR, and
- Deformation sensing instrumentation.

The following is a practical subsidence monitoring plan that takes into consideration the potential subsidence mechanisms, discussed in Section 1.4, as well as challenges related to accessibility on the steep mountainous terrain and extended periods that the site is under snow cover. If subsidence is observed, an adaptive management plan (AMP) will be initiated to further monitor deformations (Section 3).

2.1 Levelling Surveys

Brucejack will establish a series of levelling monitoring points in both the main VOK zone and the West zone. These surveys will serve to provide a calibration/check on the potential deformation detected by other monitoring methods. These precision levelling surveys will be completed annually in late summer, when snow cover is at it's lowest, and will be limited to those areas in which safe personnel access is possible.

Establishing stable reference survey monuments that have the capability to survive the significant seasonal processes that occur in alpine environments subjected to high snowfall is not practical. Therefore, the broader application of this monitoring technique, beyond an initial survey to establish a baseline for the site, is best suited as an adaptive management strategy to monitor localized subsidence if surface deformations are observed.

2023 update:

Brucejack has been trialing localized GNSS radio transmitters at the WRD. These beacons will be able to provide real time feedback with up to 6 months of battery life. Mounts are currently being made to increase data accuracy from +/- 20mm to +/- 10 mm , a reasonable deviation given the shifting weather conditions and the overall displacement that would be observed in a subsidence event.

The beacons will be implemented at the centroid of the zones as they come within 30m of the crown pillar. Above ground mounts are currently being designed so the pelican cases housing the beacons are not buried by snow – which can affect reading accuracy.

Once the reliability of these beacons can be proven with regular ground-based survey's on the WRD, they could start implementation on the zones identified in Figure 2-1.

2.2 Annual Photogrammetry

Environmental conditions at the Brucejack Mine result in few days in which cloud cover is low enough for photogrammetry to be used as a routine monitoring tool. This is further compounded by the requirement for specialist equipment and operators to be available on site at precisely the right time. Where weather, visibility, and snow free conditions allow, Brucejack will endeavour to complete an annual low elevation survey of terrestrial surfaces above underground mining areas (Figure 2-1). Unmanned Areal Vehicles (UAV) or “Drones” will be used to capture photographs for comparison of surface deformations between subsequent annual photogrammetry surveys if conditions permit.

2023 Update:

Brucejack has invested in a Matrice 300 RTK drone capable of real time surveys and photo overlays. The flights will be conducted when snow has cleared over the identified mining horizons. Since no mining is taking place this year within the 15m crown pillar, a general flight will be performed rather than detailed zone mapping with 2m contour level spacing. This will continue year over year until a zone approaches 30m within the crown pillar
If a zone does commence mining within 30m of the crown pillar, a more detailed flight will be undertaken with 1m contour intervals for the mining zones listed in Figure 2-1

Figure 2-1: Photogrammetry location showing the relationship between mining areas and surface features

2.3 Remote Sensing Alternatives

2.3.1 InSAR

InSAR uses radar images taken from a low earth orbiting satellite. Subsequent images are compared to produce an interferogram which can be used to determine ground displacement. The bare rock surfaces of the terrain around the Brucejack Mine site provide excellent reflectors for the radar data suggesting that the InSAR method could be the ideal solution for monitoring ground deformation. Measurement precision is typically in the order of 1 cm with a 1 m by 1 m pixel size. In ideal conditions, precision can be as good as 1 mm. InSAR satellite interferometry is not required as a part of the subsidence monitoring plan; however, it is a technology that can be explored to determine if it is a candidate for use at the mine site.

Brucejack and the Brucejack technical team will approach one of the InSAR service providers to determine whether the mine's location and aspect is amenable to the use of InSAR data. Should InSAR be deemed suitable for use at the Brucejack Mine site the SMMP will be updated to include the use of InSAR in the monitoring plan.

2023 Update:

Brucejack will not be undertaking inSAR imagery. Given the highly erosive environment from snowpack movement and wind erosion, 1mm accuracy will not yield more information, and in fact prove to have more noise in the data. The +/- 10mm results from GNSS beacons will be sufficient, along with visual confirmation with photogrammetry.

2.3.2 LiDAR

LiDAR surveys are not required as a part of the subsidence monitoring plan. However, in 2019 Brucejack obtained a comprehensive LiDAR scan of the mine area. This 2019 scan data can be used as a basis for comparing observational information when future survey data becomes available.

2023 update:

Lidar will not be used as a standard, but will be referenced if no other leveling survey or photogrammetry results

2.4 Reporting

An annual subsidence monitoring report will be prepared by a qualified person to support submission of Brucejack's Annual Reports to the British Columbia Ministry of Energy and Mines. The report will review the location of mining activities, proximity to the crown pillars, and summarize the annual photogrammetry data in relation to any surface subsidence observed since the previous annual subsidence monitoring report. The use of GNSS remote beacons will also supplement the photogrammetry data and a cumulative elevation displacement chart will be shown year over year. The report will detail location and magnitude of subsidence and any adaptive management activities that were triggered to further monitor deformation.

Remote sensing technology is rapidly developing. High resolution survey technologies that are considered as cost prohibitive and data intensive today are rapidly being refined and scaled for commercial uses. A key component of the annual report is to review and update the SMMP annually to ensure that it is up to date and that the most appropriate available technologies are used for monitoring subsidence at this mine site.

3 Adaptive Management Plan

An AMP for subsidence monitoring would be triggered if subsidence is observed on the ground surface. Also, if a concern is raised that underground mining will induce a surface subsidence.

When triggered, the AMP will include the following steps:

1. **Ensure the safety of workers:** This may include the egress of underground miners and cordoning off surface mining infrastructure in a zone of potential subsidence influence. If the subsidence immediately threatens worker safety, a "Stop Work Order" should be placed on immediate work areas and staff removed from the area and reported to appropriate authorities.
2. **Evaluate magnitudes and extents:** Brucejack's geotechnical engineers will evaluate the subsidence and geology to determine the risk potential that the subsidence will impact surface infrastructure, the work areas for staff and the environment.
3. **Monitoring:** A localized precision levelling monitoring programme will be developed by Brucejack's geotechnical engineers to monitor deformations. Typically, this will include installing survey monuments within the observed subsidence and peripherally, around the perimeter immediately outside of the area. The geotechnical engineers will determine the locations of surveys and the frequency of the measurements.
4. **Documentation:** Brucejack's geotechnical engineers will document the subsidence and deformation survey data that should be included in the Annual Subsidence Report.
5. **Revise the Mining Methods:** Based on the evaluation completed by Brucejack's geotechnical engineers, it may be necessary to revise the mining methods in order to limit future events.

6. **Update the Subsidence Monitoring and Management Plan:** Based on the evaluation completed by Brucejack's geotechnical engineers, it may be necessary to revise the SMMP.

4 Summary

A review of the site-specific conditions and factors affecting the potential for surface subsidence at the Brucejack Mine indicate a very low probability that noticeable subsidence at surface will occur. The two potential subsidence mechanisms identified for a mine of this nature are an unravelling progressive crown pillar failure and plug failure. Both of these potential mechanisms are mitigated by the mining practices used at this mine. These mining practices include the tight placement of cemented pastefill in the mined-out stopes and the installation of cable bolts in the upper stopes to reinforce the crown pillar.

Periodic high precision leveling surveys will be performed in the crown pillar and adjacent areas to provide broader assessment of potential ground movement.

Remote sensing technology is rapidly developing. High resolution survey technologies that are considered as cost prohibitive and data intensive today are rapidly being refined and scaled for commercial uses. It is important to review and update this SMMP annually to ensure that monitoring practices are evaluated to the latest technologies.

Dear Mr. Chang,

Re: Preliminary Assessment of Subsidence Potential for the Brucejack Project - FINAL

1.0 INTRODUCTION

BGC Engineering Inc. (BGC) is pleased to provide you with the following preliminary assessment regarding the potential for surface subsidence due to excavation of the proposed Brucejack Project mine workings.

This discussion is intended to support the Environmental Assessment (EA) phase of the project, currently being undertaken by Pretium and their environmental consultant Rescan.

A review of the site specific conditions and factors affecting the potential for subsidence at the Brucejack property indicates a very low probability that significant subsidence will occur.

2.0 BACKGROUND

2.1. Definition of Subsidence

Subsidence is a natural and man-made phenomena associated with a variety of processes including compaction of natural sediments, groundwater dewatering, wetting, melting of permafrost, liquefaction and crustal deformation, withdrawal of petroleum and geothermal fluids, and mining of coal, limestone, salt, and metallic ores. Most subsidence is either created or accelerated by human activity.

Mine subsidence can be defined as ground surface movements that occur due to the collapse of overlying or adjacent strata into mined out voids, which expresses itself in cracks, fissures, step fractures, pits or sinkholes, troughs, or sags.

Subsidence is an inevitable consequence of underground mining – it may be virtually undetectable, of significant magnitude but localized, or gradual, continuous and extensive over very large areas. Subsidence may occur immediately following mining, or be delayed for decades due to a variety of factors.

2.2. Subsidence Mechanisms and Controlling Factors

(Note: The following discussion is sourced primarily from SME, 1986; Marcus, 1997).

A number of geologic and mining parameters can affect the magnitude and extent of subsidence. These include the thickness of extracted materials; overlying mining areas; depth of mining; dip of mining zone; competence and nature of mined and surrounding rock masses; near surface geology; structural characteristics and geologic discontinuities; faults, fractures and lineaments; in-situ stresses; degree of extraction; surface topography; groundwater (including water elevation and fluctuation); method of mining; rate of advance; backfilling; and time.

These factors have been recognized and examined in detail in the literature. Included below is a brief discussion of some of those factors, with particular emphasis on those that are more typical of hard-rock mining-related subsidence.

- Ore Thickness: There is a direct relationship between the thickness of the extracted materials and the amount of surface subsidence that may result, making it an important factor in subsidence predictions. A greater ore thickness generally results in a greater amount of surface subsidence.
- Multiple Ore Zones: Where multiple mining horizons exist, subsidence which occurs in one area increases the likelihood of similar events in other areas, because the strata have been disturbed.
- Ore Zone Depth: A general consensus among industry experts is that subsidence is often *independent* of depth, refuting the previously held notion that surface subsidence can be prevented by leaving sufficient thicknesses of overburden. While this may prolong the time period before subsidence effects are observed at the surface, the possibility for subsidence is generally not changed. Bulking / swelling of material failing into mined out voids may impact the magnitude of subsidence, but will not prevent it entirely, regardless of depth.
- Dip of Ore Zone: Where the mining horizon is inclined, subsidence becomes skewed and mitigation measures such as pillars become less effective.
- Competence of Mine Floors and Roofs / Stope Footwalls and Hanging walls: The competence of mine excavation surfaces is critical in the initiation of subsidence events, since they propagate from these areas. Weak poor quality rock permits the fall of overlying strata, and may compact more easily, resulting in a greater likelihood and severity of subsidence. Conversely, **good quality rock around the periphery of an excavation limits the failure of overlying strata, resulting in a lower likelihood and severity subsidence.**
- Nature of Overlying Rock and Overburden: The strength of the overlying strata above the mining horizon is a factor in the timing and extent of subsidence.
- Surface and Near-Surface Geology: Surface and near-surface soils and unconsolidated materials tend to emphasize subsidence effects, because they behave in an inconsistent manner. They are an important factor relative to hydrologic

impacts of subsidence because they affect the exchange of surface water and groundwater.

- Geologic Discontinuities: **Faults, folds, and other inconsistencies in the overlying and surrounding strata may increase subsidence potential.** The disturbance of equilibrium forces by mining can trigger movement along a fault plane. Faults may also weaken the overlying strata and trigger subsidence in materials that may otherwise show desirable properties. Subsidence effects related to faulting may be localized about the fault structure, or may occur as increased subsidence magnitudes over a more regional area. Joints and fissures in the strata also affect subsidence but on a smaller scale.
- Degree of Extraction: The amount of pillar support is directly related to the timing and extent of subsidence. Lower extraction ratios result in greater thicknesses of pillars, which tends to delay and decrease subsidence. As the amount of pillar support is decreased, either by mine design or as a result of pillar extraction, subsidence occurs more rapidly and extensively. Complete removal of pillars without backfill is almost always followed by subsidence, with surface manifestations being a function of upward propagation to the surface.
- Surface Topography: Sloping ground like hillsides tends to emphasize the surface manifestation of subsidence, while it is less accentuated on flatter ground and in valleys.
- Groundwater: Drainage gradients may be altered by disturbance of the strata around mine areas. Rocks may become weakened by saturation, and erosion patterns could change. Where surface water is present, it may migrate more easily to fractures and fissures in the strata and into the mine area and may induce subsidence. Subsidence may also occur as a result of dewatering to facilitate underground mining in some rock types.
- Mining Method: The extent and magnitude of subsidence is dependent on the mining method(s) used to extract the ore. **The inclusion of appropriately designed crown, sill, and rib pillars into the geometry may significantly limit the effective extent and magnitude of subsidence.**
- Backfilling: **Partial or complete mine backfilling reduces subsidence and is dependent upon the type and extent of backfilling. However, it is important to note that backfilling does not necessarily eliminate subsidence entirely.**
- Time: The amount of subsidence has been observed as a direct function of time. Surface effects are delayed in room-and-pillar mining for some time, unless the pillars are removed. In block caving mines, surface effects are often noticeable soon after the initiation of caving.

As noted above, the geologic configuration of an ore deposit directly influences the nature and magnitude of potential surface subsidence. Shallow mining operations within flat layers of relatively weak sedimentary or evaporite deposits (e.g. coal, salt, potash) typically represent the most unfavorable configuration in terms of subsidence magnitudes and zone of

influence. In contrast, vein-type deposits typically have relatively limited ore thicknesses, are relatively steeply dipping, and typically have a strong host rock mass. **The principal risks for the safety of people and property located at surface above vein-type deposits is often concentrated above crown pillars and represents a relatively limited zone of influence at surface.**

The potential for mine induced subsidence is strongly related to the mining method and resultant mine geometry. The selection of the mining method mainly depends on the configuration of the deposit (e.g. size, depth, extent, orientation). Stope mining techniques like those proposed for the Brucejack Project, combined with the development of adits, drifts, and shafts, have historically been the most prolific form of hard-rock metals mining and has been done at both large and small scales. Stope mining is applicable to most vein-type ore bodies typical of base and precious metals deposits. The subsidence created by stope mining is usually the result of unintended cave-ins, inadequate support, pillar robbing, mining too close to the surface, and eventual collapse of the workings over time as the inevitable consolidation of the strata takes place. **Most often subsidence occurring as a result of stope mining techniques is limited to the hanging wall side of underlying stopes. In many cases, the degree of surface subsidence that occurs from stope mining is both isolated and relatively minor.** However, in some cases, particularly where extensive mining by this technique has been employed (e.g. Butte Mine, Montana; Hollinger Mine, Ontario), the resulting subsidence can result in significant surface impacts.

Subsidence above underground mines can be categorized into two distinct types: continuous and discontinuous. Continuous subsidence is characterized by a usually slow, smooth, and flexible readjustment of the ground surface that has no abrupt changes. This well-known and generally well understood phenomenon induces topographical depressions without major failures, leading to a dish-shaped feature on surface. In most cases the maximum amplitude in the centre of the depression is on a decimetric to metric scale. Continuous subsidence typically occurs in mining operations within flat layers of relatively weak sedimentary or evaporite deposits (e.g. coal, salt, potash).

Discontinuous subsidence is characterized by the gradual to sudden appearance of a generally irregularly-shaped depression or collapse crater at surface, resulting in localized large surface displacements, on the order of metres to tens of metres. Subsidence resulting from failures or caving of stopes is commonly discontinuous. As shown in Figure 2-1, failure modes that result in discontinuous subsidence include plug failures, progressive block raveling due to lack of adequate confinement / in-situ stress, de-stratification, chimneying disintegration, and block caving.

Figure 2-1. Common Failure Mechanisms of Shallow Stopes in Hard Rock Mines (after Bétournay, 1995)

The deposit and rock mass properties also have a significant influence on subsidence potential. Displacements within the rock mass at the periphery of underground workings can be discontinuous, sudden, and irregular. **A strong rock mass above vein-type deposit mine workings will tend to prevent any underground instabilities progressing towards the surface if the mining depth is sufficient.**

Active mine stability is generally studied for short-term projects. In contrast, subsidence can occur over very long time scales (i.e. decades to centuries). Time is therefore a fundamental factor in subsidence development. Time related factors effecting subsidence include the long term reduction in rock strength due to micro-fracturing under continuous loading conditions.

Some rock types are very sensitive to this effect (salt, gypsum, clay) while some exhibit less sensitivity (granite, quartzite). Strength reductions typically range from 20% to 50%, based on laboratory testing. The ageing of a rock mass also can affect its long term strength characteristics. Ageing is a chemical process that modifies the rock mass properties due to imposed variations in environmental conditions. In particular, the introduction of changes to the water and oxygen can have a significant impact of the quality and competency of a rock mass over time.

2.3. Subsidence Monitoring

Subsidence monitoring should be carried out over the life of the mine, including post-closure. Pre-mining high-resolution topographic surveys are useful in establishing base case conditions to be evaluated against as mining progresses.

Subsidence monitoring measurements are based upon a survey of the vertical and horizontal displacements that take place at known reference points on the ground surface. A variety of specific methods may be used depending on the objectives, site, density of monitoring points, duration and cost. Automatic data acquisition systems have been utilized and are gaining acceptance. The actual range of subsidence varies between a few feet to as much as several hundred feet vertically; horizontal displacement may occur as well. It is important in monitoring subsidence that full coordinates (x, y, z) are measured in order to track the progress of ground movements.

2.4. Subsidence Mitigation

Post-mining stabilization techniques to mitigate subsidence include backfilling, grouting, excavation and fill placement, and blasting. The extent to which post-mining stabilization techniques can be relied on to mitigate subsidence damage is uncertain, as they require assessment of long-term stability. Current analytical and empirical methods to predict the very long-term stability characteristics of mining districts need significant improvement. This is particularly the case for vein / stope mining methods.

3.0 GEOTECHNICAL CONDITIONS AT THE BRUCEJACK PROPERTY

This section presents a summary of the geotechnical conditions and geologic structure within the footprint of the proposed Brucejack Project excavations, and summarizes the geotechnical model used to assess the potential for surface subsidence. Work completed for the current study focuses on the Brucejack Project's West Zone (WZ) and Valley of Kings (VOK) mineralized zones. The discussion below is sourced largely from BGC (2013).

3.1. Overburden

The overburden in the area of Brucejack Project consists of a veneer of well-graded glacial till over bedrock. Grain size varies from sand to gravel, with some silt and clay, and variable quantities of cobbles and boulders. Clasts are subrounded to rounded, and color varies from

orangey brown to grey. Overburden thickness varies but is generally less than 5 m and often less than 1 m. A thin (often less than 0.5 m, but occasionally up to 3.0 m) layer of sandy organics overlies the overburden.

3.2. Rock Mass Conditions

For the purposes of this study, the rock mass has been categorized as “fresh rock” or “weathered rock”. The near-surface weathered rock mass is distinguished from the underlying fresh rock by an increased fracture frequency and a slightly higher degree of alteration characterized by iron oxide staining on joint surfaces (Photograph 1). The interface depth between weathered and fresh rock is estimated to range between 10 and 50 m, based on core logging and underground mapping of existing workings.

Photograph 1. Typical Weathered Rock Zone (Outlined in Red)

The fresh rock at Brucejack has an average Geological Strength Index (GSI) rating that typically ranges from 70 to 85, and average unconfined compressive strength (UCS) of approximately 100 MPa. The fresh rock is classified using standard terminology as 'Good' to 'Very Good' and 'Strong to Very Strong'. The weathered rock at Brucejack has an average GSI ranging from 60 to 65, and an average UCS of 40 to 50 MPa. The weathered rock is classified as 'Good' and 'Medium Strong'. Additional details on the geotechnical properties for Brucejack rock mass can be found in BGC (2013).

3.3. Geologic Structure

3.3.1. Major Faults and Regional Structure

The Brucejack Project area includes a number of major faults and corresponding surface lineaments. These are summarized in BGC (2013), and on Table 2-1.

The major regional lineaments near the Brucejack Project are the Brucejack Fault lineament, the Upper Treaty Glacier lineament and the Treaty Creek lineament.

The Brucejack Fault Zone truncates several site-scale faults at the western extent of the Brucejack Project, and thus has been interpreted as post-dating site-scale deformation events. Structural orientations parallel to the inferred Brucejack Fault lineament were commonly observed in downhole structural measurements across the property. All interpreted structural domains include sets oriented along the Brucejack Fault Zone with dips ranging from 56˚ to vertical.

The Upper Treaty Glacier lineament is a prominent high angle topographic lineament north of the Brucejack Project area. Although not associated with a specific fault set, similarities in regional topography and drainages make it likely that parallel structures will be prevalent throughout the study area. The Upper Treaty Glacier lineament appears in drill hole and underground mapping data in the northern regions of the property, and appears locally as a moderately strong shear and joint set.

The Treaty Creek lineament strikes east-southeast and extends north to the Iskut River Fault. The lineament marks the contact between the Hazleton Group and Bowser Lake Group rocks to the north of the property, and is a common orientation for valleys and drainages in the region. It is expected that lineament-parallel steep structures will be prevalent throughout the study area.

The level of knowledge with respect to site-scale faulting is greater for the WZ than the VOK. The VOK mineralized zone is bound to the west by the Brucejack Fault Zone, is surrounded to the north and south by northeasterly-trending fault traces, and is crossed by a southeasterly-plunging syncline. Oriented core measurements from a geotechnical drill hole drilled less than 100 m away from, and parallel to, the Brucejack Fault Zone showed significantly higher variability than other geotechnical drill holes in the VOK, indicating a potential zone of fault-related structural disturbance in the westerly extents of the mineralization.

3.3.2. Structural Domains and Design Discontinuity Sets

Structural domains for the Brucejack Project have been previously defined in BGC (2013). In general, the geologic structure across the property is highly variable in both dip and dip direction. Dominant fabrics include moderately to steeply-dipping southeast-striking structures, moderately-dipping southwest to northwest-striking structures, moderately to

steeply-dipping easterly-striking shear sets, and vertical north to north-northwest striking structures. Shallowly dipping (<20˚) sets are less common but have been identified due to their potential for adverse failure geometries in the backs of underground excavations. Vein-parallel structures, including faults, should be assumed to be present in the walls of the stopes.

4.0 MINING METHOD AND PROPOSED CROWN PILLAR

The Brucejack Project Feasibility Study mine plan is shown in plan view in Figure 4-1 and in isometric view in Figure 4-2. The total width of the mining footprint will range from 650 m (east to west) to 1125 m (north to south). This footprint area includes both the Valley of Kings and West Zone proposed underground workings, and the main access decline between them. Topography varies considerably in the project area, but the estimated maximum depth of mining is approximately 600 m below ground surface. Dewatering is currently proposed to occur through a sump and pump system as mining proceeds (i.e. no dewatering wells are planned).

Figure 4-1. Mine Development and Infrastructure, Plan View (Tetra Tech, 2013)

Figure 4-2. Mine Development and Infrastructure, Isometric View (Tetra Tech, 2013)

The proposed underground mine design supports the extraction of 2,700 t/d of ore through a combination of transverse 'Long Hole Open Stoping' (LHOS) and longitudinal LHOS. Paste backfilling of stopes is integral to the mine plan to maximize orebody recovery and mining productivity. Sublevels will be accessed from the main ramps on a 30 m vertical interval that is defined by the planned stoping heights (Figure 4-3).

Figure 4-3. Mine Development and Infrastructure, VOK Long Section (Tetra Tech, 2013)

Level development will follow the general strike of the various lenses (Figure 4-4), providing access to the mineralized zones in a manner that promotes transverse mining wherever possible. Level development will generally be in the hanging wall, with hanging wall drives typically including excavations for sumps, refuges, transformers, remucks, paste fill line, and raise accesses. Stope access crosscuts will be on 15 m spacings, with the exception of those levels where sill extraction or near-surface weathered ore will be recovered in smaller units that are designed on 10 m spacings.

Figure 4-4. Mine Development and Infrastructure, VOK 1270 Level (Tetra Tech, 2013)

Transverse LHOS is a non-entry method, with remote mucking of blasted ore required once the drawpoint brow is open to the extent where the operator may be exposed to uncontrolled sloughing from the stope cavity. Once emptied of ore, the stope will be remotely surveyed with cavity monitoring equipment. A barricade will be constructed in the drawpoint and the stope backfilled to just below the floor elevation of the top level. Crushed aggregate or ROM waste may be spread over the fill surface to reduce backfill dilution and increase trafficability of mucking equipment for the next lift of the stope.

The primary means of backfilling at the property will be paste fill, which will be generated from unclassified mill tailings mixed with adequate cementitious binder to meet the strength requirements. Regular strength paste fill is commonly required where there will be re-exposure of vertical stope walls. Stopes that will not be re-exposed by adjacent mining are proposed to be backfilled with unconsolidated waste and/or by paste fill with sufficient binder to remove any risk of future liquefaction (low-strength paste fill). High-strength paste fill will be required in the lower portion of all primary and secondary stopes that will be undercut by sill extraction from below.

The minimum recommended crown pillar thickness for the Brucejack mine is 15 m, determined using a number of industry standard geotechnical methods and techniques (BGC, 2013). The maximum recommended transverse stope span is 10 m for all stopes immediately below the crown pillar. Transverse stopes immediately below the crown must be

tight-filled as much as practicable to reduce the potential for crown pillar collapse. The crown pillars are also to be supported with 5.0 m long single strand bulbed cable bolts on 2.5 m spacing, to assist with enhancing stability conditions and preventing the onset of subsidence mechanisms.

5.0 POTENTIAL FOR SURFACE SUBSIDENCE AT THE BRUCEJACK PROJECT

A preliminary review of the site specific conditions and factors affecting the potential for subsidence at the Brucejack Project indicates a very low probability that significant subsidence will occur. This conclusion is based primarily on the following facts:

- Because the overburden is thin (< 5 m) and generally has a low clay content, dewatering of the project area is not anticipated to cause consolidation and subsidence in the overburden.
- The rock mass at Brucejack is classified as Good to Very Good and Medium Strong to Strong, using industry standard classification systems. Rock of this quality around the periphery of an excavation limits the failure of overlying strata, resulting in a lower likelihood and severity of subsidence.
- The Brucejack deposit is a steeply-dipping vein-type deposit. The principal risks for the safety of people and property located at surface above vein-type deposits is often concentrated above crown pillars and represents a relatively limited zone of influence at surface.
- The proposed mine footprint, while substantial, is not on the scale of other vein-type mining districts where significant subsidence has typically been recorded (e.g. tens to hundreds of hectares vs. thousands to tens of thousands of hectares).
- The proposed mining method of long hole open stoping with complete paste backfilling significantly reduces post-mining void volumes. Most often subsidence occurring as a result of stope mining techniques is limited to the hanging wall side of underlying stopes. In many cases, the degree of surface subsidence that occurs from stope mining is both isolated and relatively minor. Complete mine backfilling further reduces subsidence potential, often to virtually undetectable levels.
- To improve near-surface stability conditions at the Brucejack Project, a minimum recommended crown pillar thickness of 15 m has been determined using a number of industry standard geotechnical methods and techniques. The crown pillars are also to be supported with cable bolts to assist with enhancing stability conditions and preventing the onset of subsidence mechanisms.

Notwithstanding the above, the presence of a number of significant regional geologic structures in the Brucejack Project area may negatively influence rock mass stability and increase the potential for mining induced subsidence. Continuous subsidence monitoring and

further study of these structures will improve the level of understanding with respect to this potential.

6.0 CLOSURE

BGC Engineering Inc. (BGC) prepared this document for the account of Pretium Resources Inc. The material in it reflects the judgment of BGC staff in light of the information available to BGC at the time of document preparation. Any use which a third party makes of this document or any reliance on decisions to be based on it is the responsibility of such third parties. BGC accepts no responsibility for damages, if any, suffered by any third party as a result of decisions made or actions based on this document.

As a mutual protection to our client, the public, and ourselves, all documents and drawings are submitted for the confidential information of our client for a specific project. Authorization for any use and/or publication of this document or any data, statements, conclusions or abstracts from or regarding our documents and drawings, through any form of print or electronic media, including without limitation, posting or reproduction of same on any website, is reserved pending BGC's written approval. If this document is issued in an electronic format, an original paper copy is on file at BGC and that copy is the primary reference with precedence over any electronic copy of the document, or any extracts from our documents published by others.

We trust the above satisfies your requirements at this time. Should you have any questions or comments, please do not hesitate to contact us.

Yours sincerely,

Subject:	Subsidence Monitoring and Management Plan		

1 Introduction

Pretium Resources Inc. (Pretium) retained SRK Consulting (Canada) Inc. (SRK) to prepare a Subsidence Monitoring and Management Plan (referenced here in as the SMMP or the Plan) for Brucejack Gold Mine as per *Mines Act* Permit M-243 Condition D.13.

Subsidence is an inevitable consequence of the extraction of minerals, liquid, or gas from beneath the ground surface. The surface expression may be of a small magnitude and localised or extend over large areas. Subsidence may occur immediately with mining or may be delayed by many years. Geology and mining methods are the main variables that dictate the magnitude of impact of subsidence and cannot be ignored.

The enclosed SMMP has evaluated the effectiveness of subsidence controls to provide an early warning of surface expression that may result in changes to terrestrial or aquatic values. Subsequently, this plan includes adaptive management measures for monitoring subsidence and developing mitigation measures as needed.

1.1 Mining Method

The underground mine comprises two main ore zones: Valley of the Kings (VOK) zone, and the West zone (Figure 1-1). The mine began commercial operation in July 2017 with production from the VOK zone. There has been no production to date in the West zone. The mining method at Brucejack is long-hole stoping; a combination of longitudinal and transverse mining is used depending on the width and orientation of the mineralized zones. The mine employs an overhand primary/secondary stoping method with cemented tailings pastefill used to backfill stopes after mining.

Predominantly, the underground development at Brucejack measures 5.5 m wide by 5.5 m high, with an increase in height to 6 m on the main ramp and crossover drives. In ore development, crosscuts are 5 m wide and 5 m high. Where stopes are to be mined, the undercut is slashed out to a total width of 15 m.

Figure 1-1: Plan View (top) and Oblique View looking West of the VOK and West zones

Underground developments are supported by installation of cable bolts in the upper stopes to reinforce the crown pillar and backfilling with waste rock and cemented tailings backfill upon completion. Supported mining methods, as such have a reduced subsidence impact when compared with alternative unsupported methods.

The mine's current production rate is approximately 3,800 tonnes per day and has an anticipated mine life of 14 years.

1.2 Geology

The Brucejack gold-silver deposit is located in the Sulphurets gold-silver-copper mining camp. The deposit is interpreted as a deformed porphyry-related gold-silver epithermal deposit. High-grade gold-silver mineralization occurs as coarse aggregates of electrum and silver sulfosalts that are hosted in steeply dipping and predominantly west- to northwest-trending quartz-carbonate vein stockwork and breccia zones within a broader halo of clay alteration and low-grade mineralization.

Mineralized veins and stockwork zones appear to have utilized lithological contacts and pre-existing structures. Epithermal veins are largely discordant to the penetrative foliation of the altered host rock, suggesting that mineralization postdates a fabric-forming event. Mineralized zones were tilted, thrusted, and sheared during Cretaceous compressional deformation.

The Brucejack Ground Control Management Plan (GCMP) classifies the rock mass into a number of "geotechnical units" based on characterization of the rock mass and the presence of major geological structures (Pretivm, 2020).

The geotechnical units in the VOK zone, described in BGC's review of underground geotechnical units (BGC, 2019), are listed in order of increasing competence:

- The weathered zone comprises near-surface rocks.
- The Fault Zone unit comprises rock identified as fault-disturbed rock. It is strong, with good RQD values (75% - 90%), and close discontinuity spacing.
- Rock mass Domain 1 includes the Volcano-sedimentary Facies (argillite portion) geological unit; it very strong, with good RQD values, and moderate discontinuity spacing.
- Rock mass Domain 2 includes the Bridge Zone Porphyry, Office Porphyry, and Silicified Rock geological units; these are strong, with excellent RQD values (>90%), and moderate discontinuity spacing.
- Rock mass Domain 3 includes the Volcaniclastics, Volcano-sedimentary Facies (sandstone-conglomerate portion), S3-Trans and ANDX units; these are strong, with excellent RQD values, and wide discontinuity spacing.

2 Subsidence

The study of mining induced subsidence has predominantly been in connection with the mining of extensive tabular mineral deposits, such as coal and potash, through either longwall or room and pillar mining.

The effects of subsidence are not limited to the vertical displacement of the ground surface but include the total of all surface effects that are associated with the extraction of minerals.

There are essentially three potential surface subsidence effects of underground mining:

- **Trough subsidence** – generally associated with the extraction of relatively flat tabular orebodies. The ground disturbance associated with the trough is generally greater than the extent of the underground workings. Cracks or fissures may be formed at the edges of the subsidence trough and reflect tensile or shear stresses in the ground surface. This is considered to be unlikely at the Brucejack Mine.
- **Collapse subsidence** – caused by the failure of the strata between the underground excavations and the ground surface. The ground disturbance associated with collapse type subsidence can vary in magnitude from a zone around an individual stope (i.e., chimney subsidence) to large areas of a mine (i.e., plug failure). Collapse type subsidence generally exhibits at surface as a sinkhole or conical depression. Cracks or fissures may be formed around the depression or sinkhole.
- **Plug failure** – generally controlled by weak, continuous geological structures in the overlying rock mass or can be initiated by the large-scale failure of pillars, either rock or backfill pillars or a combination of both. Plug subsidence is generally controlled by one or more major structural features, such as a fault or dyke, which provides a continuous plane of weakness or where the shear strength of the rock mass is overcome at a critical stage of mining or through the failure of regional mine support such as pillars or backfill. Structural geology studies conducted on the Brucejack deposit have not identified continuous features that might act as the failure surfaces for a plug type failure.

2.1 Subsidence Assessment

The conventional approach to assessing subsidence effects over metal mines is to consider the stability of the crown pillar formed between the upper limit of mineral extraction and the ground surface. The initial crown pillar stability assessment was conducted by BGC Engineering Inc. (BGC) and described in the original Brucejack Mine Feasibility Study (BGC, 2013). The approach used by BGC in their assessment comprised analytical, empirical and numerical methods.

In order to supplement the approaches used in the initial crown pillar assessment, SRK used an alternate approach. The approach described by Bétournay (2004), examines the effects of the proposed excavations on the overlying rock to identify the portion of the rockmass that can be mobilized and the likelihood of this resulting in failure through to surface.

The Bétournay methodology is based upon the assumption that failure of underground openings is progressive and will not stop until the following is achieved:

- There is a significant improvement in rock mass properties;
- The effective span is reduced by the support provided by the failed rock;
- A stable rock arch is formed; and/or
- The space available for failed rock to occupy is insufficient with the result that the failure chokes off.

The method proposed by Bétournay (2004) utilises the technique that Janelid and Kvapil (1966) proposed for the design of sub-level caving operations. This empirical method calculates the volume of rock that is mobilized when collapse of the stope back occurs and caving is initiated. The caving process can be halted by many factors such as increased rock strength, natural arching of the roof span, and caving hang ups but in the worst-case scenario, the cave will continue until the space available for the caved material to occupy has been completely filled.

The volume of rock that fails into any given excavation is related to stope dimensions, the unfilled volume and the bulking factor of the overlying rock mass. This volume of rock can be defined by the draw cone, or ellipsoid represented in Figure 2-1, and the volume of rock in which movement takes place is defined by the limit ellipsoid. If the ground surface lies within the radius of the draw cone, then complete failure through to ground surface will occur. If the ground surface lies within the radius of the limit ellipsoid, then subsidence of the ground surface can be expected.

Figure 2-1: Diagram illustrating the effects on ground surface of the draw and limit ellipsoids, Bétournay (2004)

SRK considered a single stope and the footprint of each of the continuous stoping blocks in the main mining zones (the VOK and West zone). An example of the footprint dimensions considered, is shown in Figure 2-2. Although the mine design calls for tight cemented pastefill to the back of the stopes, the assessment adopted a conservative approach and assumed that a 5 m unfilled gap was left above the backfilled stope.

For all the scenarios considered, the unravelling progressive failure described by Bétournay (2004) becomes self limiting with the limit ellipsoid height being less than 5 m for all cases. As this is a third of the design crown pillar thickness, no disturbance would be expected to be noticeable at the ground surface.

Figure 2-2: Crown pillar footprint dimensions for the West zone

3 Monitoring Plan

Subsidence monitoring plans typically include combinations of visual observations, aerial and satellite photogrammetry and LiDAR, ground-based precision surveys and deformation sensing instrumentation. The topography, mountainous terrain and seasonal snow and ice cover at the Brucejack Mine pose unique challenges to the development of an appropriate subsidence monitoring plan. as the surfaces being monitored for subsidence are under snow cover for extended periods of the year. Furthermore, the supported mining methods employed underground, drastically reduce the magnitude of subsidence effects below the level of detection without the use of precision levelling survey techniques.

The following is a practical subsidence monitoring plan that takes into consideration challenges related to accessibility on the steep mountainous terrain and extended periods that the site is under snow cover. If subsidence is observed, an adaptive management plan (AMP) will be initiated to further monitor deformations (Section 4).

3.1 Annual Photogrammetry

During snow free conditions, Pretivm will complete annual low elevation survey of terrestrial surfaces above underground mining areas (Figure 4.1). Unmanned Areal Vehicles (UAV) or “Drones” are to be used to capture photographs for comparison of surface deformations between subsequent annual photogrammetry surveys.

InSAR satellite interferometry uses radar images taken from a low earth orbiting satellite. Subsequent images are compared to produce an interferogram which can be used to determine ground displacement. The bare rock surfaces of the terrain around the Brucejack Mine site provide excellent reflectors for the radar data suggesting that the InSAR method could be the ideal solution for monitoring ground deformation. Measurement precision is typically in the order of 1 cm with a 1 m by 1 m pixel size. In ideal conditions, precision can be as good as 1 mm.

SRK suggests that Pretivm and the Brucejack technical team approach one of the InSAR service providers to determine whether the mine’s location and aspect is amenable to the use of this approach.

3.2 LiDAR

The price point for LiDAR data comes at a much higher cost than photogrammetry and InSAR. It would be unrealistic to require annual LiDAR surveys to monitor subsidence. In 2019, Pretivm obtained a comprehensive LiDAR scan of the mine area. This data can be used as a basis for comparison when future survey data becomes available.

3.3 Precision Levelling Survey

The implementation of a precision levelling monitoring programme would require the installation of stable reference survey monuments that have the capability to survive the significant seasonal processes that occur in alpine environments subjected to high snowfall. These precision levelling surveys would have to be completed in late summer when snow cover is at it’s lowest and would be limited to those areas in which safe personnel access would be possible.

Although the levelling method provides the greatest precision (sub-millimetre measurements are possible), the limits on areal coverage resulting from the terrain and the challenge of maintaining reference survey monuments, means this method is not the most applicable for broad site-wide subsidence monitoring. SRK suggest that a single levelling traverse is established on the long axis of the main VOK and another traverse along the long axis of the West Zone ore zone. These would serve to provide a calibration/check on the potential deformation detected by other monitoring methods. Broader application of this monitoring technique is best suited as an

adaptive management strategy to monitor localized subsidence if surface deformations are observed.

3.4 Reporting

An annual subsidence monitoring report will be prepared by a qualified person to support submission of Pretivm's Annual Reports to the British Columbia Ministry of Energy and Mines. The report will review the location of mining activities, the mined geology, and summarize the annual photogrammetry data in relation to any surface subsidence observed since the previous annual subsidence monitoring report. The report will detail location and magnitude of subsidence and any adaptive management activities that were triggered to further monitor deformation.

A key component of the annual report is to review and update the SMMP to ensure that it is kept up to date and that the best available technologies are used for monitoring subsidence at this mine site.

Figure 3-1: Relationship of current and planned underground excavations and surface features

4 Adaptive Management Plan

An AMP for subsidence monitoring would be triggered if subsidence is observed on the ground surface. Also, if a concern is raised that underground mining will induce a surface subsidence.

When triggered, the AMP will include the following steps:

1) **Ensure the safety of workers:** This may include the egress of underground miners and cordoning off surface mining infrastructure in a zone of potential subsidence influence. If the subsidence immediately threatens worker safety, a “Stop Work Order” should be placed on immediate work areas and staff removed from the area and reported to appropriate authorities.

2) **Evaluate magnitudes and extents:** Pretivm’s geotechnical engineers will evaluate the subsidence and geology to determine the risk potential that the subsidence will impact surface infrastructure, the work areas for staff and the environment.

3) **Monitoring:** A localized precision levelling monitoring programme will be developed by Pretivm’s geotechnical engineers to monitor deformations. Typically, this will include installing survey monuments within the observed subsidence and peripherally, around the perimeter immediately outside of the area. The geotechnical engineers will determine the locations of surveys and the frequency of the measurements.

4) **Documentation:** Pretivm’s geotechnical engineers will document the subsidence and deformation survey data that should be included in the Annual Subsidence Report.

5) **Revise the Mining Methods:** Based on the evaluation completed by Pretivm’s geotechnical engineers, it may be necessary to revise the mining methods in order to limit future events.

5 Summary

A review of the site-specific conditions and factors affecting the potential for subsidence at the Brucejack Mine indicate a very low probability that noticeable subsidence at surface will occur. The two potential subsidence mechanisms identified for a mine of this nature are an unravelling progressive crown pillar failure and plug failure. Both of these potential mechanisms are mitigated by the mining practices used at this mine. These mining practices include the tight placement of cemented pastefill in the mined-out stopes and the installation of cable bolts in the upper stopes, to reinforce the crown pillar.

Periodic high precision leveling surveys are strongly recommended in the crown pillar and adjacent areas to provide broader assessment of potential ground movement. There is potential to use InSAR or LiDAR surveys to accomplish this. The benefit of utilising satellite InSAR measurements is that radar images from the past can be used to gain a better understanding of historic deformation. The use of InSAR data could help in the planning and optimisation of other monitoring methods and placement of survey instruments.

Remote sensing technology is rapidly developing. High resolution survey technologies that are considered as cost prohibitive and data intensive, are rapidly being refined. It is important to review and update this SMMP to ensure that monitoring practices are evaluated to the latest technologies.

WTP	Water treatment plant

LIMITATIONS OF REPORT

This Plan is intended to guide construction activities in order to minimize erosion and sedimentation at the Brucejack Gold Mine Project site. This is not an assessment of terrain stability nor is it an assessment of the design of the structures and facilities themselves. The contents of this report are based on the information available at the time it was produced and on the judgement of ERM Consultants Canada Ltd. (ERM) staff. The evaluation presented here will not be substituted for on-site inspection of conditions. Evaluation of potential erosion and sediment delivery must be conducted on site in conjunction with construction activities.

1 PURPOSE

This Surface Erosion Prevention and Sediment Control Management Plan (the SEPSC Management Plan) provides guidance for erosion prevention and sediment control (EPSC) measures to be used during the Construction and Operations phases of the Brucejack Gold Mine Project (the Project; Figure 1-1). The intention is that this Plan informs the development of site-specific EPSC plans and can help to estimate the effort required for EPSC activities during the Construction phase, when the majority of erosion and sediment issues are expected to occur.

For the purposes of this Plan, erosion control refers to those measures that aim to reduce the amount of soil that is detached by water or wind. Erosion control measures include, but are not limited to, re-vegetation, the use of mulches and rolled erosion control products (RECPs), soil bioengineering, slope breaks, surface roughening and terracing, buffer strips, and timing of construction. The primary goal of erosion control is to stabilize sediment, preventing its release from the source.

Whereas erosion control is proactive, sediment control refers to reactive, remedial measures that aim to collect and retain sediment that has already been detached and mobilized. The main purpose of sediment control is to prevent sediment from entering waterways. Measures of sediment control include, but are not limited to, sediment fences, check dams, wattles and fascines, berms and earth dikes, and sediment retention pools. Some of these measures, such as check dams, wattles, and fascines, can function as both prevention erosion and sediment control. For example, a check dam used as a slope break will slow water, simultaneously reducing surface erosion and promoting sediment deposition.

Figure 1-1

Brucejack Gold Mine Project: Location and Major Components

PRETIVM

2 PERFORMANCE OBJECTIVES

The SEPSC Management Plan provides guidance for achieving the following performance objectives during the Construction phase of the Project:

- ongoing compliance with regulatory commitments, guidelines, and objectives;
- implementation of environmental protection measures in a timely, effective, and cost-efficient manner;
- integration of EPSC management activities with other management and monitoring programs;
- interception and diversion of non-contact water away from work areas using ditches, berms, or other diversion structures to prevent erosion and sedimentation; and
- descriptions of typical best management practices (BMPs) for several expected activities during the Construction and Operations phases.

3 SCOPE

This Plan is applicable to the Construction phase in the following Project areas:

- Brucejack Access Road;
- Mine Site;
- not potentially acid-generating (NPAG) Quarry;
- Mine Site gravel borrow sources and other borrows;
- Knipple Transfer Area;
- Bowser Aerodrome;
- Bowser Camp; and
- Brucejack Transmission Line and Tide Staging Area.

The potential construction activities in these areas have been reviewed to determine the potential sites of erosion and sediment delivery to watercourses. Vulnerable sites typically requiring EPSCs include:

- stream and wetland crossings;
- spoil areas;
- borrow areas;
- sensitive soils (e.g., unconsolidated morainal materials);
- cut-and-fill construction; and
- ditches.

4 RELEVANT LEGISLATION AND REGULATIONS

Relevant federal and provincial legislation and regulations include the following.

- British Columbia (BC) *Environmental Management Act* (2003). Regulates the discharge of air contaminants, liquid effluent, and refuse into the environment, and regulates the management of hazardous wastes.
- BC *Mines Act* (1996a). Provides guidance and approvals for all activities related to the Project, including exploration, development, operations, closure, and reclamation.
- *Health, Safety, and Reclamation Code for Mines in British Columbia* (BC MEMPR 2008). Under the *Mines Act* (1996a), requires the proponent to provide:
  - designs and details for water management structures, water storage, and water treatment facilities;
  - the source, use, and water balance for any water required during Operations;
  - a plan for erosion control and sediment retention; and
  - a reclamation plan.
- *Fisheries Act* (1985b). The *Fisheries Act* was amended in 2012. The changes to the *Fisheries Act* include a prohibition against causing *serious harm to fish* that are part of or support a commercial, recreational, or Aboriginal fishery (Section 35); provisions for flow and passage (Sections 20 and 21); and a framework for regulatory decision-making (Sections 6 and 6.1). Section 36, the key pollution prevention provision, prohibits the deposit of harmful substances into waters frequented by fish, unless authorized by regulations under the *Fisheries Act* or other federal legislation.
- Metal Mining Effluent Regulations (SOR/2002-222). Environmental monitoring and surveillance programs of effluent discharges are requirements of the Metal Mining Effluent Regulations pursuant to the *Fisheries Act*.
- *Canada Water Act* (1985a). Provides the framework for joint federal-provincial management of Canada's water resources.
- BC *Water Act* (1996b). Administers the allocation and management of surface waters in BC. It is the primary legislation for regulating surface water diversion, storage, use, and management of water quality. Approvals and licences under provincial water acts are required to authorize the construction of works for the purposes of diverting, storing, or using water, or causing changes in and about a stream for any purpose.
- *Navigation Protection Act* (1985d). Regulates works that interfere with navigation built in, on, over, under, through, or across navigable waters in Canada.
- *International River Improvements Act* (1985c). Enacted to ensure Canada meets its obligations under the *Boundary Waters Treaty* of 1909. The intent of the treaty is to ensure that Canada's water resources in international waters are developed and used in the best national interest.

Under the Act, a permit is required if the construction of the Project changes the natural flow of an international river (i.e., the Unuk River).

- BC *Forest and Range Practices Act* (2002). Requires that road construction adheres to codes provided in the Forest Service Road Use Regulation (BC Reg. 70/2004), which focuses extensively on erosion prevention.

The following documents were used as primary sources for mitigation and management measures:

- *Water and Air Baseline Monitoring Guidance Document for Mine Proponents* (BC MOE 2012);
- *Forest Practices Code of British Columbia Forest Road Engineering Guidebook* (BC MOF 2002);
- *Forest Management on Fans* (Wilford, Sakals, and Innes 2005);
- *Operational Statement for Overhead Line Construction* (DFO 2007 [Appendix A]); and
- *Operational Statement for Maintenance of Riparian Vegetation in Existing Rights-of-Way* (DFO 2007 [Appendix B]).

It should be noted that the DFO operational statements have been super ceded by 'Measures to Avoid Causing Harm to Fish and Fish Habitat' (http://www.dfo-mpo.gc.ca/pnw-ppe/measures-mesures/index-eng.html). The included operational statements are relevant tools that can be used in developing site specific mitigations and management measures to comply with the *Fisheries Act* as per by 'Measures to Avoid Causing Harm to Fish and Fish Habitat'.

5 ENVIRONMENTAL PROTECTION AND MANAGEMENT

This section provides an overview of general environmental protection plans and resources that can be applied to specific surface EPSC issues at the Project.

5.1 EROSION PREVENTION AND SEDIMENT CONTROL PLANNING

Erosion control measures are practices that aim to reduce the amount of soil that is detached by wind or water. Erosion control measures include, but are not limited to, re-vegetation, the use of mulches and RECPs, bio engineering, slope breaks, surface roughening and terracing, and timing of construction. The primary goal of erosion control is to stabilize soils, preventing them from becoming detached from the source and re-deposited as sediment elsewhere.

Sediment prevention is the reactive remedial measures that aim to collect and retain sediment that has already been detached and mobilized. The main purpose of sediment prevention is to prevent sediment from entering waterways. Measures of sediment prevention include, but are not limited to, sediment fences, check dams, wattles and fascines, berms and earth dikes, and sediment retention ponds. Some of these structures, such as fascines and wattles, can function both as erosion control and sediment prevention. For example, a check dam used as a slope break will slow water, simultaneously reducing surface erosion and promoting sediment deposition.

5.1.1 Site-Specific Plans and Engineered Designs

Implementation of the SEPSC Management Plan will require an ability to adapt to changing site conditions, and perhaps modifications to construction plans. Prior to beginning construction at a specific site, the Environmental Monitor will collaborate with construction personnel on site to develop a site-specific plan that identifies any soil-disturbing activities. The plan will consider all ground-cover disturbance activities planned for the site and the proposed BMPs associated with each activity, using this SEPSC Management Plan for guidance. The site-specific plan will be flexible and adaptable. All construction personnel working at the site will be advised of the plan's goals and their responsibilities in order to implement the plan successfully.

A kick-off field visit will be conducted for each construction site to determine if a site-specific plan will be required. The field visit will consist of an on-site assessment by the construction managers and environmental monitors. At each construction site, any key areas will be identified prior to beginning work. These include:

- areas requiring protective measures, such as riparian management areas (RMAs);
- upslope locations where runoff could enter the site and potential routes for diverting the runoff around, or routing it through, the site; and
- highly erodible areas (e.g., steep slopes, unconsolidated morainal material).

Prior to beginning work, the work boundaries at each site will be identified and flagged to confine construction activities within the designated boundaries. Based on information gathered during the site assessment, a supply of EPSC materials such as culverts, riprap geotextiles, and sediment fencing will be provided at the site for immediate use to avoid construction delays.

5.1.2 Response and Contingency Plans

Implementations of BMPs are the key to preventing erosion and controlling sediment on a construction site. Proper and timely implementations of BMPs are often sufficient to meet total suspended solids (TSS) concentrations in runoff at levels that meet guideline criteria (Section 7.2).

Management for EPSC at the Project will be active and adaptive, incorporating ongoing inspection, maintenance, and re-evaluation of the effectiveness of the implemented BMPs. During emergencies, such as extreme precipitation events, it is extremely important that contingency measures are in place, to be implemented if required.

The structure of this SEPSC Management Plan reflects a hierarchy of responses to potential erosion and sediment transport events resulting from construction. BMPs and a corresponding inspection, maintenance, and monitoring program constitute the basis of EPSC planning. If the results of monitoring indicate that the BMPs on a site are not adequate to meet adjacent stream water quality objectives, the first step is an assessment of current BMPs to confirm that they are installed correctly and functioning as intended. The next step is reassessment of the existing BMPs to evaluate whether they are appropriately sized for the contributing drainage area and to determine whether more frequent maintenance or an alternative or additional BMP may be required.

As a contingency measure, installation of sediment retention structures has been considered in the event that reassessment and correction of existing BMPs do not achieve a sufficient reduction in TSS levels. Sediment retention structures are a form of BMP, but they are addressed independently in this report (Appendices C, D, and E) because in many cases their design, installation, and operation require additional considerations. Numerous size and design options exist depending on site-specific requirements, ranging from small sediment pools or traps to detain local runoff (e.g., at culvert inlets) to large sediment ponds requiring engineered design.

Sediment control ponds are a contingency measure for managing surface runoff from clearing, grubbing, and other surface construction activities. Some pond capacity will be available at the Mine Site for emergency storm water management or where BMPs are not effective in preventing erosion or controlling detached sediment. Discharge from the ponds will be monitored for compliance with BC Water Quality Guidelines (BCWQGs) for TSS concentrations.

5.1.3 Site Resources for Erosion Prevention and Sediment Control

A supply of EPSC equipment and materials will be maintained in locations that are easily identifiable and accessible to construction sites in the Project area. These EPSC supplies will include materials for routine BMP maintenance and repair as well as contingency supplies to be used in the event of an emergency. Supplies may include, but are not limited to:

- geotextile, polyethylene sheeting, and/or other forms of RECPs;
- shovels and other hand tools;
- tarps;
- sediment fencing;
- piping;
- approved grass seed and spreader;
- stakes and signage;
- crushed and washed NPAG gravel or rock riprap;
- mulching materials such as bark, straw, or sawdust;
- sandbags (filled with clean sand, or with a clean sand source readily available); and
- portable water pumps and hoses.

The on-site supply of EPSC materials will be regularly inventoried, and materials that are used up will be promptly replaced, as determined by the Construction Management Team.

5.2 EROSION PREVENTION AND SEDIMENT CONTROL BEST MANAGEMENT PRACTICES

Erosion and sediment production can be minimized on a site through the implementation of BMPs, both prior to, during, and immediately following Construction. This section contains an overview of the EPSC BMPs generally applicable to activities that have been identified to occur during Project Construction. A detailed summary table and typical drawings are included in Appendices C, D, and E.

5.3 EROSION PREVENTION AND SEDIMENT CONTROL– TYPICAL CONSTRUCTION ACTIVITIES

5.3.1 Work in or near Streams

Stream crossing upgrades are not anticipated during the Construction phase; however, controls at road crossings may need to be installed as there may be potential for increased sediment delivery to streams at these locations. Construction near stream channels will adhere to all applicable legislation and guidelines (e.g., Appendices A and B) to minimize disturbance to stream banks and riparian habitat. For work within riparian areas, consideration will be given to salvaging rooted shrubs and maintaining as much vegetation as feasible.

While stream crossing construction in not anticipated, if it were to occur, it will be scheduled for dry or low water periods, whenever feasible. Surface Water Hydrology baseline reports (Rescan 2011a, 2013a, 2014) may be consulted for general seasonal discharge variability of creeks related to the Project.

Fording may be permitted in creeks that are classified as non-fish bearing, where fish habitat is not located within 250 m of the proposed ford, and where creek substrate is not likely to cause significant sediment production. This information on designated fish habitat in the Project can be confirmed by referring to the Fish and Fish Habitat Baseline Reports (Rescan 2011b, 2012, 2013b). If fording is considered, clean logs or large rocks will be placed in the creek such that machine tracks or tires do not contact moving water and such that banks are not disturbed. Any material placed in the creek will be removed once the fording is complete. Fording creeks will be limited to one crossing per machine and will only be considered a temporary measure. When fording is required for more than one week, a temporary crossing will be installed.

Work in or near streams will adhere to the guidelines in the *Riparian Management Area Guidebook* (BC MOF 1995) and the *Standards and Best Practices for Instream Works* (BC MWLAP 2004). An additional resource is the interactive BC Ministry of Environment Instream Works website (BC MOE 2011).

If there are work activities not currently planned in and around fish bearing waters, such as stream crossings along the Brucejack Access Road, an authorization to cause *serious harm to fish* will be applied for from Fisheries and Oceans Canada (DFO) before proceeding. A site-specific EPSC plan including all instream works will be completed, in addition to the permitting requirements. Guidance for site-specific plans for work in fish-bearing streams may be found in the *Fish-Stream Crossing Guidebook* (BC MOF 2012).

5.3.2 Cut and Fill Construction

Cut and fill construction is also known as side cast or partial bench construction. This will be the most common building technique used during upgrades along the Brucejack Access Road. These cut and fill slopes are also the design elements of the road that have the highest surface erosion potential.

Cuts may be excavated out of steep hillslopes with poor soils that cannot support side casting, as in the case of full bench construction. Fills constructed by side casting in steep terrain have the potential to over steepen slopes. In areas where side casting is unsuitable, the road design will consider end-hauling cut material to a designated spoil site.

Cuts and fills will be re-vegetated as soon as feasible after construction is complete. During construction, the use of mulches or mats in conjunction with seeding may be required to minimize erosion prior to the establishment of new vegetation.

Steep sections of the road will be constructed using full bench construction. This type of construction uses only a cut and is preferred where the slope is too steep to support a fill. This method is often used in conjunction with steep rocky terrain. These areas have a low surface erosion potential when constructed in rock.

5.3.3 Construction in Sensitive Soils

Soil sensitivity to erosion depends primarily on grain size (BC MOF 1993). Fine-grained material such as fine sands and silts are the most erodible. Clay is also erodible; however, clays exhibit cohesion such that the individual clay particles can be difficult to detach, providing erosion

resistance. The erodibility of surficial materials is heightened in areas where the materials are deposited in a thin veneer over bedrock.

Organic materials that are intact on the soil surface provide a measure of erosion resistance by protecting the soil from rain splash and runoff erosion. However, once disturbed, organic materials are highly susceptible to erosion and entrainment due to their large proportion of fine-grained materials. Once removed from the soil surface, organic materials must be handled carefully during earth-disturbing construction activities. Organic soils are generally found in gently sloping to flat areas (e.g., wetlands), decreasing the chances of detachment and entrainment by runoff.

The length of time required to settle particles of entrained sediment is directly related to grain size. The selection of appropriate sediment control measures also depends in part on grain size. The smaller the particle, the more difficult it is to remove from suspension. Coarse particles do not require long settling times and are therefore relatively easy to remove from suspension. Sediment fences are suitable for retaining coarse particles, but they do not function well for retaining fine-textured soils. Fine sands and silt particles are considerably more difficult to retain than coarser sands, requiring slower water velocities and a longer retention time. Removal of fine-grained particles from entrainment is often only feasible with berms, earth dikes, or sediment retention basins (smaller pools or larger ponds). The removal of clay particles from entrainment generally requires large settling ponds, which are unfeasible along the Brucejack Access Road corridor. Although smaller sediment retention pools will help to remove fine particles from suspension, they are not likely to settle clays. This emphasizes the importance of preventing erosion of fine grained materials at the source to avoid expensive and elaborate sediment control systems.

Construction in sensitive materials will be conducted during periods of dry weather whenever feasible. Where materials are deposited in veneers, removal of the sediment from the bedrock will reduce the likelihood of erosion. Organic soils, along with other sensitive fine-grained materials, will be excavated wherever feasible as a first step to site development. The excavated materials will be removed to a stable spoil location and stored for future reclamation activities. Re-vegetation and stabilization of sensitive sites will be prioritized as soon as construction in these areas is complete. Identification of sensitive soils will be done by the Environmental Monitor on site.

5.3.4 Construction-induced Slope Failure

Construction-induced slope failure can occur in unstable terrain, during periods of heavy rainfall, or anywhere that road construction creates excess disturbance to a hillslope. Work in sensitive or potentially unstable areas will not be conducted during heavy rainfall or otherwise adverse weather. Adverse weather conditions that may trigger a stop work order are outlined in Section 5.3.7.

Geohazard risk assessment and terrain stability field assessment (TSFA) documents will be consulted prior to beginning construction, in particular along the Brucejack Access Road.

Installation of gabions or retaining walls may be needed to reduce excavation, contain bank material, or prevent slope failure. The significance of observed seepage zones may dictate the

application of other measures, as prescribed by the on-site engineer, to reduce the likelihood of slope failure during construction.

5.3.5 Clearing

Clearing and grubbing activities expose large quantities of soil, leaving it highly susceptible to erosion. To minimize erosion during clearing and grubbing, the following measures will be implemented.

- Prior to beginning work, perimeter sediment control measures will be established at the downslope edges of the site and along any streams or waterbodies. The type and configuration of sediment control measures will vary depending on specific site characteristics and may include sediment fences, temporary or permanent diversion ditches, and earth or straw bale dikes.
- Work will begin at the top of the construction footprint and move downslope in order to maintain a buffer of vegetation.
- Machine operators will work along slope contours whenever feasible to reduce the potential for channelization and gullying on the slope.
- Soil will only be stripped from areas that will be required to be disturbed to support construction. The width of clearings for any site access will be kept to a minimum.
- Understory vegetation and ground cover will be retained wherever feasible, such as in areas that are only subject to temporary disturbance.
- In areas with exposed soil where construction will be inactive for an extended period of time, temporary covers such as brush, RECPs, or polyethylene sheeting may be used as a protective measure.
- Whenever feasible, clearing and grubbing work will be conducted in dry weather, and work will be temporarily halted during periods of extreme or sustained heavy precipitation.
- As the site is cleared, slope length can be minimized by installing slope breaks such as straw wattles or brush berms. Slopes will be textured or terraced to reduce runoff velocity and volume.
- Topsoil that is removed from a site will be stockpiled for future use in site reclamation. BMPs for stockpiles are described in Section 5.3.12.
- Depending on site characteristics, temporary diversion ditches may be required to collect runoff from areas upslope of the construction works. Flow in these ditches will be directed to stable, vegetated, level areas where the water can infiltrate into the ground. Ditches susceptible to erosion may be lined with geotextiles or riprap.
- Ground surface protection will be concentrated on exposed and steep slopes around the edges of the site, close to drainage channels and at any obvious drainage features.
- Supplemental approaches such as mulching, topsoiling, and/or hydroseeding/hydromulching may be used in conjunction with seeding depending on specific site requirements. Live wattles and fascines may be used as a form of re-vegetation.

5.3.6 Snow Handling

Where construction is carried out in areas with snow cover, proper handling of cleared snow is required. Large amounts of topsoil or organic matter can be entrained during snow removal activities. As this snow melts, fine materials can be transported with the meltwater. To prevent the delivery of fine materials into stream channels, snow will be piled in undisturbed areas with low slopes at a minimum of 30 metres from any waterway. Sediment fencing or berms may be placed around snow piles to trap sediment and prevent erosion if deemed necessary.

5.3.7 Adverse Weather Shutdown Triggers

The potential for surface erosion during periods of severe weather may facilitate shutdown / stop work orders of construction activities. Stop work orders will be based on safety concerns, environmental effects, and protection of Project infrastructure. Stop work orders can be initiated by the Environmental Monitor(s), Environmental Coordinator, Environmental Manager, Health and Safety Manager, Construction Manager(s), or Mine Manager.

Triggers resulting from adverse weather that may cause a shutdown include:

- periods of very high rainfall or extended periods of high rainfall;
- indicators of erosion and instability are encountered;
- unsafe conditions may exist or environmental damage may occur; and
- soils are visibly soft or muddy and associated sediment-laden waters or sediment are flowing towards watercourses or where such conditions are reasonably anticipated to develop.

Traffic restrictions will be put in place in areas that are subject to shut down of construction activities.

Construction activities that may need to be shut down prior to a forecasted maximum rainfall include:

- subgrade construction on slopes over 50% or where naturally occurring slope failures occur;
- bridge or culvert construction;
- work near fish bearing waters;
- work in areas of sensitive soils;
- work near landslides or unstable terrain;
- areas with significant amounts of groundwater seepage; and
- any work designated in the SECSP Plan as requiring dry weather only.

5.3.8 Overlanding Floodplains and Alluvial Fans

Floodplains and alluvial fans are areas of concern during Construction phase activities because they may be subject to flooding during periods of high flow, and because close proximity to streams shortens the distance that sediment-laden water travels from the site to the stream, allowing for direct delivery of sediment into the waterway. Construction in floodplains and fans will be scheduled for dry periods, to the extent feasible. During construction, areas of bare ground will be covered with brush or RECPs if deemed necessary. Slopes on floodplains and fans will be stabilized with riprap armouring. After construction is complete, re-vegetation will take place as soon as feasible. There is limited topsoil inherently available for reclamation in these areas so re-vegetation will be challenging. The selection of plants and planting methods that may be used for re-vegetation will be researched as per the Reclamation and Closure Plan.

5.3.9 Steep Slopes

Slopes greatly increase the potential for erosion if soil or erodible materials are present in sufficient volumes. Runoff velocities and erosion generally increase in proportion to slope steepness. Construction on soil-mantled slopes at moderate to extreme steepness (greater than 26%), as defined by the British Columbia Terrain Classification System (Howes and Kenk 1997) requires special care in the form of diversion measures, slope drains, and slope stabilization measures.

Construction-induced slope failure can occur in unstable terrain, during periods of heavy rainfall, or anywhere that construction creates excess disturbance to a hillslope that is not bedrock. Work in potentially unstable areas will not be conducted during heavy rainfall or otherwise adverse weather. Adverse weather conditions that may trigger a stop work order are outlined in Section 5.3.7.

Geohazard risk assessment and TSFA documents will be consulted prior to beginning construction.

The following are BMPs for steep slopes.

- Maintaining a buffer strip of natural vegetation at the base of a slope is a highly effective method for erosion control and may reduce the need for additional EPSC measures.
- Diversion ditches (temporary or permanent, depending on construction plans and site requirements), earth dikes, or a combination of ditches and dikes can be used to divert runoff from the face of exposed slopes. Temporary diversions must remain in place until slopes have been permanently re-stabilized.
- Flow in diversion ditches will be directed to stable, vegetated, level areas where the water can infiltrate into the soil. Alternately, flows may be directed to a sediment pool or pond. Ditches susceptible to erosion will be lined with geotextiles or NPAG rock.
- Slope drains (temporary or permanent, depending on construction plans and site requirements) may be used alone or in conjunction with diversion ditches. Temporary slope drains may be pipes made of corrugated metal, chlorinated polyvinyl chloride, high-density polyethylene, or other suitable material. Permanent slope drains may be blasted channels in

rock. The inlet and outlet of slope drains will be protected (e.g., using an energy dissipator) to prevent erosion and undercutting.

- Areas cleared to construct a slope drain will be re-vegetated and stabilized. Runoff from slope drains will be directed to stable, level, vegetated areas or to a sediment pool or pond.
- Gabions or retaining walls may be required as permanent measures to stabilize slopes, particularly for slopes that are too steep to establish and retain vegetation. These structures will be designed by a professional engineer.
- Stabilization of slopes will be prioritized as soon as construction in these areas is complete. In areas where re-vegetation is feasible, hydroseeding and hydromulching are effective methods for steep slopes and do not require the seedbed preparation, which may be impractical in steep areas.
- Length and gradient of slopes can be minimized by installing slope breaks, such as terraces or berms. General recommendations for spacing of slope breaks are given in Table 5.3-1.

Table 5.3-1. Recommended Spacing for Slope Breaks

	Slope Gradient	Slope Break Spacing (m)
Steep slopes	2:1 (50%)	6
	3:1 (33%)	11
	4:1 (25%)	14
Long slopes	15-25%	15
	10-15%	24
	6-10%	38
	3-6%	61
	<3%	91

Source: BC MEMNG (2002).

5.3.10 Ditches and Non-contact Water Diversions

5.3.10.1 Ditches

Erosion in gullies and ditches constructed in erodible soils or on steep slopes will be controlled by armouring with vegetation, riprap, geotextiles, or other means to protect the soils and reduce flow velocities. Temporary mitigation for ditch erosion may include check dams constructed with brush or logs. Rock check dams will provide a more durable, permanent method of preventing ditch erosion. In rare instances, temporary ditches constructed in fine soils will be lined with geotextiles to avoid erosion.

Ditchlines will be re-vegetated along with all other exposed soils along the road. Regular inspection of ditches will be conducted to check that associated cuts are not slumping into the ditches and vegetation is established. Inspection will also be conducted to check that catch basins and culverts

remain clear. Ditch stabilization measures that are disturbed by grading or other road maintenance activities will be repaired immediately or removed if no longer required.

Ditchlines at the Mine Site will be directed initially (prior to completion of Phase 1 of the Contact Water Pond [CWP]) to sumps which will be pumped to the water treatment plant (WTP). When directing ditch flow to stable, vegetated, level areas, consideration is given to confirming water can infiltrate into the soil and not cause further erosion. In the case of the NPAG Quarry, the quarry floor will be configured to slope inward to act as a settling basin. Water will be withdrawn (pumped) from the top of this settling basin and directed downslope, where it will drain to Brucejack Lake (BGC 2015).

5.3.10.2 Non-contact Water Diversions

Non-contact water diversions will be installed to prevent non-contact water from entering a work area. Diversion channels will be constructed to the west of the Operations Camp and the south and east sides of the laydown area. These channels will typically follow access roads or the base of rock cuts. A geotextile liner will be used as necessary with riprap to prevent erosion damage to the channel if the scour velocity is exceeded. The diversion channels will discharge directly to Brucejack Creek or Brucejack Lake. Where deemed necessary, geotechnical recommendations will be followed for diversion stability, such as maximum slope angles, rock bolting, and shotcrete. The stability of side slopes will be further addressed as required, by lining protection (riprap or high-density polyethylene lining as warranted by flow velocities).

Further information regarding the design of non-contact water diversions can be found in the Water Management Plan (BGC 2015).

5.3.11 Road Surfaces

Erosion from the road surface will be minimized by proper road design and construction, as well as regular maintenance. Maintenance will include grading and replacement of surface material as required to avoid washboarding, potholes, and puddling of surface water. Surfaces will be capped with appropriate material if erosion problems persist. Roads will be graded to produce a crown, and in-slope or out-slope will be undertaken to avoid puddling. Grader operators will be instructed not to blade material into stream channels or ditches.

Runoff from the roadway will be collected in drainage structures and ditches and directed through the use of ditch blocks into culverts. Inlet basins and settling pools will be constructed at the culvert inlet where necessary to capture fine sediment washed into ditches from cut slopes or the roadway. These structures, especially settling pools, will be maintained regularly to clean out sediment. Low flows of sediment-laden runoff may be directed to vegetated areas. Sediment-laden water will not be directed into natural streams or into areas that drain immediately into natural streams.

5.3.12 Spoil Sites

Soil will be removed from construction sites and stabilized in an appropriate location. Due to long transportation distances, the use of the Brucejack Access Road for transporting construction spoil

materials for use in future site reclamation may be unfeasible. Therefore, the spoil sites associated with road construction will be permanently stabilized, rather than temporarily stockpiled. Spoil sites will be located in the road right-of-way in accordance with standard forest road engineering practices. Spoil materials will not be placed on sensitive soils or in environmentally sensitive areas. Disposal sites will be planned in advance of construction and will be sufficiently stable to support the material, have very low potential for erosion to a stream, and have little or no impact on other forest resource values. Whenever feasible, disposal sites will be constructed in permanent locations to minimize the disturbance and re-handling of material.

As soon as feasible, spoil piles will be graded and seeded to prevent wind and water erosion and to initiate long-term stabilization. If immediate re-vegetation is seasonally unfeasible, materials will be protected by a temporary cover such as RECPs or polyethylene sheeting, as required. Woody debris from cleared sites may be used as a reclamation material, as it creates protected microsites to promote germination and adds organic matter and nutrients. Cover soil will be roughened in order to promote seed catch and germination and to control erosion. Until spoil piles are stabilized by vegetative cover, temporary perimeter sediment controls (e.g., sediment fencing, berms) will be installed around the piles. These temporary measures will be inspected regularly and removed when they are determined to be no longer necessary.

5.3.13 Borrow Sites

Organic and fine-grained soils removed from borrow sites will be stockpiled for use in future reclamation. All borrow sites will be re-sloped to a stable configuration and re-vegetated or otherwise reclaimed after construction is complete.

Perimeter ditches or berms will be placed upslope of the borrow area prior to the start of construction to divert fresh or non-contact water from entering the area where feasible. Should borrow areas sit idle for extended periods, protection of erodible materials by temporary covers such as RECPs or polyethylene sheeting will be considered. At borrow sites, where water from screening and washing activities produces sediment-laden water, this water will be detained on site to reduce suspended sediment prior to discharge from the area.

5.3.14 Contact Water and Settling Ponds

5.3.14.1 Contact Water Pond

The contact water ditches will direct contact water to the CWP, which is sized to contain runoff from the 24-hour, 200-year return period rain-on-snow event (~ 50,000 m^3). The contained water will be pumped to the permanent WTP.

The CWP will be constructed on bedrock with the exception of the north side where an embankment will be required. The combination of bedrock and a liner will minimize seepage from the pond. Construction will start with the installation of sediment control measures such as diversion ditches and silt fences, followed by stripping of any topsoil and overburden, and excavation of bedrock by ripping or drilling and blasting with removal to Brucejack Lake.

Details of the CWP design can be found in the Water Management Plan (BGC 2015).

5.3.14.2 Sediment Ponds / Traps

Sediment ponds are designed to collect and store sediment for extended periods of time. The retention time provided by their relatively large size allows ponds to be capable of settling and retaining smaller grain sizes than sediment traps or swales. Sediment ponds may be temporary or permanent structures and require design by a professional engineer. Sediment ponds are most effective when used in conjunction with other BMPs and will not be used as a stand-alone measure for sediment control.

Small, temporary ponding areas referred to as sediment pools or sediment traps may be used to manage localized overland flow. These structures do not require design by a professional engineer, but they have limited capacity to retain small particles and are only suitable for relatively small contributing drainage areas (less than 1.2 ha). The simplest application of sediment pools is in conjunction with cross drain culverts, where they can be easily constructed by widening and levelling a portion of the drainage ditch that routes flow to the culvert. Sediment pools with gravel outlets may also be installed at the perimeter of construction sites, formed by excavation and/or by constructing an earthen embankment.

Sediment pools will be monitored and maintained on a regular basis until the site is permanently stabilized. Sediment will be periodically removed and stockpiled in a designated location. After site stabilization, pools or traps will be removed and disturbed soil areas resulting from removal will be stabilized.

5.3.15 Concrete Placement

During construction of concrete foundations or pads controlling run-off from the work site, the following is required (BC MOE 2014):

- prevent release of deleterious substances, including sediment, and ensure that all works involving the use of concrete, cement, mortars, and/or other Portland cement or lime-containing construction materials will not deposit (directly or indirectly) sediments, debris, concrete, leachate concrete fines, wash or contact water into or about any watercourse;
- cast-in-place concrete must remain isolated from water inside sealed formed structures until cured (approximately 48 to 72 hours), as concrete leachate is highly toxic to fish and other aquatic life;
- when working in areas near surface water, make available a carbon dioxide (CO_2) tank with regulator, hose, and gas diffuser during concrete work to neutralize pH levels should a spill occur. Staff must be trained in its proper use;
- provide containment facilities for wash-down water from concrete delivery trucks, concrete pumping equipment, and other tools and equipment;

- prevent any water that contacts deleterious uncured or partly cured concrete (during activities like exposed aggregate wash-off, wet curing, or equipment washing) from directly or indirectly entering any watercourse or storm water system;
- isolate and hold any water that contacts uncured or partly cured concrete until the pH is between 6.5 and 8.0 pH units and the turbidity is less than 25 nephelometric turbidity units (NTU), measured to an accuracy of +/- 2 NTU;
- if works are being undertaken in stream, monitor pH frequently in the watercourse immediately downstream of the isolated worksite until the works are completed. Emergency measures should be implemented if downstream pH has changed more than 1.0 pH unit, measured to an accuracy of +/- 0.2 pH units from the background level, or is below 6.0 or above 9.0 pH units; and
- immediately report any spills of sediments, debris, concrete fines, wash, or contact water of reportable quantities.

6 CONSTRUCTION AREA EROSION PREVENTION AND SEDIMENT CONTROLS

This section describes the construction activities that may require EPSC measures within specific infrastructure areas. Management objectives and measures (Appendix C) together with reference to typical BMPs (Appendix D and E) are provided.

6.1 BRUCEJACK ACCESS ROAD

The existing access road was constructed as a temporary, all-season exploration access road that commences at km 216 on Highway 37 and continues westward to Brucejack Lake, a distance of 73 km. There are four access road sections described below (km 0 is located at the intersection with Highway 37):

- Section 1 - km 0 to 35 - road completed in 2011 to 2013;
- Section 2 - km 35 to 59 - road existing prior to 2011;
- Section 3 - km 59 to 71 - Knipple Glacier Road; and
- Section 4 - km 71 to 75.3 - Lakeshore Drive.

The entire length of the access road is referred to as the Brucejack Access Road. The all-weather gravel sections 1 and 2 are collectively referred to as the Lower Brucejack Access Road.

Near Highway 37, the Brucejack Access Road crosses through the Nass Basin Ecosection, a basin of low relief encircled by sharply rising mountains that includes the Boundary Ranges to the west and the Skeena Mountains to the east. Bedrock underlying this basin is predominantly volcanic and sedimentary, and the relief is more subdued than that found in other adjacent ecosections. The soils and rock materials in the area of the Brucejack Access Road are generally considered NPAG (Chapter 5 of ERM Rescan 2014).

A number of geohazard types have been identified along the Brucejack Access Road, including debris and snow avalanche, flood, and rockfall (Table 6.1-1). These locations will be monitored as necessary and mitigation applied where appropriate as per the Geohazards Management Plan.

Table 6.1-1. Geohazard Types Identified along the Brucejack Access Road

Access Road Segment	Road km Reference (+/- 50 m)	Hazard Type
Wildfire Creek (0 to 17 km)	2.3 to 2.7	Debris avalanche
Scott Creek (17 to 35 km)	30 to 31.5	Snow avalanche
	33.8 to 34.2	Debris flow

(continued)

Table 6.1-1. Geohazard Types Identified along the Brucejack Access Road (completed)

Access Road Segment	Road km Reference (+/- 50 m)	Hazard Type
Bowser River to Knipple Glacier (35 to 59 km)	36.6 to 36.7	Flood
	38.0 to 38.3	Flood
	39.5 to 40.0	Snow avalanche
	41.0 to 45.4	Flood
	43.7 to 44.2	Snow avalanche
	45.2	Snow avalanche
	45.3 to45.4	Rock fall impact
	47.8 to 51.8	Flood
	52.0 to 54.0	Flood
	54.8 to 55.8	Snow avalanche
	55.7 to 56.7	Snow avalanche
	57.7 to 58.0	Rockfall
	57.8 to 59.3	Snow avalanche
	58.7 to 59.0	Rockfall
Brucejack Lake	71.2 to 71.3	Rockfall
	72.1 to 72.5	Rockfall
	71.7 to 73.0	Snow avalanche

6.1.1 Description of Works – Construction

Road access to the Brucejack Mine Site will be via the existing 73-km-long exploration access road from Highway 37 (Figure 6.1-1), which will be upgraded to allow for construction and operational traffic. The Brucejack Access Road refers to the entire length of the road and includes the segments of Lakeshore Drive, the Knipple Transfer Area, and the Mine Site. The upgrades to the Brucejack Access Road to accommodate mine traffic (Brucejack Access Road Upgrade Prescription, Cypress Forest Consultants Ltd. 2014) will include minor re-alignments of the sharper curves, reductions of the steeper grades, short sections of double lanes for pull-out areas, widening in areas of reduced visibility, and additional surfacing of some sections; however, it is not anticipated that any upgrades to stream crossings will be required.

The Brucejack Access Road begins at about km 216 on Highway 37, crosses the Bell-Irving River on a single-span bridge and follows the valley of Wildfire Creek to Scott Creek drainage, passes Todedada Lake in the Todedada Creek Valley and proceeds over the pass to follow Scott Creek in the Bowser Valley, which it follows to the toe of the Knipple Glacier. A constructed ramp allows tracked vehicles to access the glacier, which is traversed for about 12 km to its apex near Brucejack Lake where a further 2 km of road leads to the Brucejack Mine Site.

The Brucejack Access Road will have a 5-m stabilized road width and a 40 km/hour design speed. To meet the standards laid out in the *Forest Road Engineering Guidebook* (BC MOF 2002) the road will have:

- a 95-m minimum stopping site distance;
- a minimum horizontal curve radius of 65 m;
- vertical curve values (K values) of 9.6 for crest curves and 8.5 for sag curves;
- favourable grades of 12% (14% for pitches less than 150 m); and
- adverse grades of 8% (10% for pitches less than 100 m).

To address safe two-way traffic along the Brucejack Access Road, the road width will be widened to 10 m (double lane) in locations with sight distances below the minimum site stopping distance of 95 m (blind vertical and horizontal curves).

The section of the Brucejack Access Road from km 71 to 75.3, referred to as Lakeshore Drive (Figure 6.1-2), descends off the Knipple Glacier and traverses open rock and gravels on the south side of Brucejack Lake to the Brucejack Mine Site. Lakeshore Drive will be realigned to address concerns identified with respect to:

- improved gradients for accessing the Knipple Glacier road;
- improved road way that reduces high, steep drop-offs;
- reduced geohazard risk due to the increased distance from avalanche slopes;
- reduced geohazard risk due to the existing Lakeshore Drive acting as a catch bench for falling rocks; and
- access to construction sand and gravel sources.

The realignment starts at approximately km 71 and travels in a northern direction. The section from approximately km 71.25 to 72.75 is on the Knipple Glacier. From km 72.75, the route travels westerly for approximately 1 km to 73.75 km; this section transects through the gravel borrow sources required for the Project. From km 73.75, the route continues in a westerly direction along the southern shore of Brucejack Lake to connect back to the existing Lakeshore Drive at approximately km 75.25.

The realignment consists of two segments with differing road design specifications. The segment from 71 km to approximately 73.76 km is a single lane road with a 5-m-wide running surface with pullouts at intervals that provide safe passage for opposing traffic. The road will support the transport of materials and supplies required for construction of the Project site and the long-term operations of the Project. Cross drain culverts will be installed where required to maintain natural drainage patterns.

The segment or road from km 73.76 to 75.25 is designed to a similar standard as for a mine haul road as defined in the *Mines Act* (1996a). The road has a running surface of 9 m, which supports the safe passage of 30-tonne articulated rock trucks. The road will also support the transportation of materials and supplies required for construction of the Project site and the long-term operations of the mine, as well as the transport of waste rock from the Mine Site to the proposed contingency East Subaqueous Waste Rock Deposition Site at the eastern end of Brucejack Lake.

6.1.2 *Erosion Prevention and Sediment Control – Implementation and Operation Measures*

The Brucejack Access Road construction and improvement work will follow the objectives of the practices presented in the *Forest Road Engineering Guidebook* (BC MOF 2002). Road and diversion ditch construction has the potential to generate surface erosion and deliver sediment yield to waterways. Maintenance will be conducted to prevent or minimize landslide risk and to provide for continuous, efficient, and controlled water drainage.

Management measures for EPSC during construction and maintenance of the Brucejack Access Road are provided below. Selecting the appropriate measure is critical to achieve the management objective during a specific construction activity. Table 6.1-2 provides a summary of the expected access road construction activities with applicable management measures and BMPs. Some applicable BMPs may not be identified in this table and will be selected on a site-specific, as-needed basis.

Table 6.1-2. Applicable Erosion Prevention and Sediment Control Best Management Practices Relevant to Road Construction / Upgrading and Maintenance

Activity	Management Objectives	Management Measures	Applicable BMP Numbers
Stream crossings/road adjacent to streams	Prevent sediment from entering streams/waterways	**Short Term** • Prior to starting work, install sediment controls (e.g., sediment fences, berms) between construction works and waterways. • Maintain ditches, cross-drain culverts, and other structures so they do not discharge water directly into streams. • Minimize disturbance to riparian vegetation. • Cover bare ground at temporarily inactive sites with brush or RECPs. • Handle excavated material on streambanks carefully. • Limit construction to dry weather periods when feasible. • Use armour/riprap in areas where bank erosion is likely. • Inspect EPSC measures after any runoff-producing rain event. **Long Term** • Conduct re-vegetation in conjunction with mulching and/or erosion mats. • Use live wattles or fascines where bank stabilization required. • Inspect and maintain EPSC measures and remove temporary measures (e.g., sediment fencing) when they are no longer necessary.	1, 4-10, 14, 16-19, 21-24

(continued)

Table 6.1-2. Applicable Erosion Prevention and Sediment Control Best Management Practices Relevant to Road Construction / Upgrading and Maintenance (continued)

Activity	Management Objectives	Management Measures	Applicable BMP Numbers
Overland floodplains and alluvial fans	Prevent erosion of slopes in floodplains, fans and, on sensitive soils	**Short Term** • Avoid construction in sensitive soils whenever feasible. • If construction in sensitive soils is required, cover bare ground at temporarily inactive sites with brush or RECPs. • Install armour/riprap along fills. • Limit construction to dry weather periods when feasible. **Long Term** • Conduct re-vegetation in conjunction with mulching and/or erosion mats. • Use live wattles or fascines where stabilization required. • Inspect and maintain EPSC measures.	1, 4-10, 14
Cut and fill construction	Maintain slope stability by preventing over-steepening, prevent sediment from entering streams/waterways	**Short Term** • Prior to starting work, install sediment controls (e.g., sediment fences, berms) between construction works and waterways. • Cover bare ground at temporarily inactive sites with brush or RECPs. • Limit construction to dry weather periods when feasible. • Consider end hauling in steep areas to avoid sliver fills and over steepening of slopes. **Long Term** • Conduct re-vegetation in conjunction with mulching and/or erosion mats. • Use live wattles or fascines where stabilization required. • Inspect and maintain EPSC measures.	1, 4-10, 14, 19, 21-24
Ditches	Prevent erosion, maintain stability of ditch structures and armouring	**Short Term** • Armour with vegetation, riprap, RECPs, or other suitable means. • Use check dams to slow runoff velocity. **Long Term** • Immediately re-stabilize if disturbed by grading or other road maintenance. • Conduct re-vegetation in conjunction with mulching and/or erosion mats, as required. • Inspect and maintain EPSC measures.	1, 4-10, 13-14, 16, 17, 20-24

(continued)

Table 6.1-2. Applicable Erosion Prevention and Sediment Control Best Management Practices Relevant to Road Construction / Upgrading and Maintenance (continued)

Activity	Management Objectives	Management Measures	Applicable BMP Numbers
Road surface erosion	Prevent erosion and delivery of sediment into streams/waterways, maintain long-term road surface stability	**Short Term** • Adhere to proper road construction guidelines, including maintaining an appropriate depth and type of surfacing material. • Use water bars as a temporary measure until ditches and culverts can be installed or repaired. **Long Term** • Grade and replace surface material as required. • Inspect and maintain EPSC measures.	2, 11, 20, 22, 24
Construction in sensitive soils	Prevent erosion and delivery of sediment into streams/waterways	**Short Term** • Prior to starting work, install sediment controls (e.g., sediment fences, berms) between construction works and waterways. • Cover bare ground at temporarily inactive sites with brush or RECPs. • Remove veneers from bedrock within road prism to remove likelihood of erosion. • Limit construction to dry weather periods when feasible. • Consider end hauling in steep areas to avoid sliver fills and over steepening of slopes. **Long Term** • Conduct re-vegetation in conjunction with mulching and/or erosion mats. • Use live wattles or fascines where stabilization required. • Inspect and maintain EPSC measures.	1, 4-8, 21-24
Spoil sites	Prevent sediment from entering streams/waterways, maintain long-term site stability	**Short Term** • Install perimeter sediment control (e.g., berms, sediment fencing) around soil disposal / stockpile sites. • Maximize distance from streams/waterways. • Avoid steep slopes or otherwise unstable sites. • Re-vegetate as soon as feasible and use temporary covers (e.g., RECPs, polyethylene sheeting) if re-vegetation is not immediately feasible as required. **Long Term** • Inspect and maintain EPSC measures and remove temporary measures (e.g., sediment fencing) when no longer necessary. • Monitor for successful re-vegetation .	1, 2, 4-10, 21-23

(continued)

Table 6.1-2. Applicable Erosion Prevention and Sediment Control Best Management Practices Relevant to Road Construction / Upgrading and Maintenance (completed)

Activity	Management Objectives	Management Measures	Applicable BMP Numbers
Borrow sites	Prevent sediment from entering streams/waterways, maintain site stability	**Short Term** • Maximize distance from streams/waterways. • Avoid steep slopes or otherwise unstable sites. • Re-slope to stable configuration after closure. • Re-vegetate as soon as feasible and use temporary covers (e.g., RECPs, polyethylene sheeting) if re-vegetation is not immediately feasible as required. **Long Term** • Monitor for successful re-vegetation.	1, 2, 4-12, 21-23
Construction induced slope failure	Prevent erosion and delivery of sediment into streams/waterways	**Short Term** • Consult TSFAs and geohazard risk assessments prior to beginning construction. • Conduct work in sensitive or potentially unstable areas in dry weather. • Identify seepage zones and other locations of potential failure prior to beginning construction. • Install retaining wall structures or gabions where necessary. **Long Term** • Inspect and maintain retaining walls.	1, 17, 18
Snow handling	Prevent delivery of fine sediment from meltwater to streams/waterways	**Short Term** • Pile snow in undisturbed areas with low slopes a minimum of 30 m from any waterway. • Minimize the amount of sediment mixed with snow during snow removal and transport, where feasible. • Install sediment controls (e.g., silt fences, berms) around snow piles containing a large amount of soil or organic matter.	1, 21-24
Adverse weather	Mitigate the potential for surface erosion during periods of severe weather	**Short Term** • Make all personnel aware of adverse weather shutdown conditions. • Conduct construction activities in sensitive areas (e.g., adjacent to streams/waterways, areas with high erosion potential) during dry weather. • Stop work before soils are visibly soft or muddy and associated silty waters or sediment are flowing toward watercourses, or where such conditions are reasonably anticipated to develop.	1

Note: For "Applicable BMP Numbers," refer to Appendix D.

Clearing and excavation leave exposed soils susceptible to erosion. The roads and ditches have the potential to intercept surface water flow at cuts, which can result in an increase in surface water runoff over the construction site. Additionally, roads and ditches may cross streams which will receive sediment if proper sediment controls are not in place and maintained. Given that these are linear infrastructure developments, space is limited within the proposed construction footprints for ponds or other large sediment control measures.

It is anticipated that all planned Project roads will be required throughout the life of mine. In the currently unforeseen circumstance of any road or road section no longer being required before mine closure, it will be deactivated and reclaimed in accordance with the Reclamation and Closure Plan (Chapter 5).

Standard EPSC BMPs will be implemented during construction along the entire length of the Brucejack Access Road, as required. Applicable management practices may include:

- using standard forest road engineering practices and procedures as described in the *BC Forest Road Engineering Guidebook* (BC MOF 2002);
- beginning construction activity in each road segment, where feasible, at the top of the slope and working down to the lowest slope;
- minimizing the slope length of each segment cleared by installing slope breaks. Slope breaks will be retained throughout the construction process or until no longer required;
- excavating small, temporary diversion ditches to collect runoff from areas upslope of the road excavation and direct it away from areas susceptible to erosion. Ditches constructed in erodible soils will be lined with an appropriate geotextile and covered with riprap armouring where ditch bottoms are susceptible to erosion;
- adverse weather conditions that may trigger a stop work order are described in Section 5.3.7;
- covering exposed slopes with a layer of branches or brush if earthworks are not scheduled to begin soon after clearing and grubbing;
- excavating catch basins around the inlet of culverts to trap coarse material that is transported in drainage ditches; and
- avoiding discharging from cross-drain culverts directly into streams. Unless they are in use as part of a stream crossing, culverts will discharge onto rock or another stable energy dissipater and then diffuse flow into established forest or wetland vegetation.

Following construction, exposed cut and fill slopes will be re-vegetated as soon as feasible. The use of temporary cover (e.g., RECP) will be considered if re-vegetation is not immediately feasible. Based on field observations, existing sumps or basins that reduce flow velocity appear to be successful in capturing silt and fine sand particles. This suggests that this type of sediment control approach will be effective along the Brucejack Access Road. Culverts will be inspected to maintain suitable sump capacity where appropriate. Regular monitoring and maintenance will be carried out to remove accumulated sediment.

6.2 MINE SITE

Non-vegetated and sparsely vegetated ecosystems dominate the Brucejack Mine Site. Ice and rock are the dominant surficial materials. Non-vegetated ecosystems include glaciers, permanent snow/ice, lakes, and ponds. Patches of snow, névé, and firn persist late into the year. Sparsely vegetated ecosystems include rock outcrops, talus, and moraine.

Vegetation community development in the Brucejack Mine Site Area is influenced by the recent deposition of the soil parent material, excessive snow pack, wind, and cold temperatures. The area is subject to the effects of frost and wind which give rise to a characteristic low plant cover. Soils are either absent or exist as thin veneers, often derived from *in-situ* bedrock weathering, remnant glacial till, and colluvium. Thin annual snowpack leads to active freeze–thaw cycles that push plants out of the soil.

6.2.1 Surface Infrastructure and Construction Activities

6.2.1.1 Surface Infrastructure

Surface infrastructure at the Mine Site (Figure 6.2-1) will include:

- camp facilities – expansion of existing facilities including an additional mine dry, bunkhouse, kitchen, sewage and administration facilities;
- ancillary buildings including a concrete batch plant, the mill and truck shop, substation and generator buildings, explosive storage facilities, metallurgical lab, fuel storage facility, an incinerator, and the tailings pipeline;
- an underground portal and related facilities such as the crushed ore conveyor;
- a lined waste rock storage facility; and
- a WTP (Construction WTP) close to the existing exploration mine WTP. This plant will be operational before development of the underground mine.

Site preparation and construction activities will include:

- development of the surface water management system, including contact and non-contact water ditches and the CWP, and implementation of other EPSC measures;
- a general earthworks program including rock cuts, pad development for mine infrastructure, and grading; and
- salvage of any available overburden materials and stockpiling for reclamation where feasible as there are limited developed soils on the Brucejack Mine Site.

6.2.2 *Erosion Prevention and Sediment Control– Implementation and Operation Measures*

Upgradient, non-contact surface flow will be diverted around the Mine Site. Existing drainage courses will be preserved as much as feasible as this typically leads to the most economical drainage design.

The Mine Site will be positively drained at all times and all contact water generated from within the Mine Site will be directed to a CWP. Water contained in the CWP will be pumped to the mine WTP for treatment prior to use or discharge.

Designed drainage systems are based on the 200-year storm event. As construction progresses, for each area disturbed, the storm drainage will be managed by temporary (or permanent) swales, ditches, sumps, pumps, and hoses/pipes. In areas of PAG rock, the contact water will be pumped directly to the Construction WTP using the temporary sumps, pumps, hoses, and pipes. The water may also be pumped indirectly to the Construction WTP by way of the Phase 1 CWP and sump pump. In areas of NPAG rock, drainage does not have to go to the CWP or WTP. This drainage will be directed to Brucejack Lake or Brucejack Creek. Basic storm water BMPs such as silt fences and poly cover to prevent erosion will be employed when appropriate. Additional information regarding storm water is found in the Water Management Plan.

Management measures for EPSC during construction and maintenance of the Mine Site are provided below. Selecting the appropriate measure is critical to achieve the management objective during a specific construction activity. Table 6.2-1 provides a summary of the expected Mine Site construction activities with applicable management measures and BMPs. Some applicable BMPs may not be identified in this table and will be selected on a site-specific, as-needed basis.

Table 6.2-1. Applicable Erosion Prevention and Sediment Control Best Management Practices Relevant for the Mine Site

Management Area	Management Objectives	Recommended Measures	Applicable BMP Numbers
Spoil sites	Prevent sediment from entering streams/waterways, maintain long-term site stability	**Short Term** • Install perimeter sediment control (e.g., berms, sediment fencing) around soil disposal sites. • Maximize distance from streams/waterways. • Avoid steep slopes or otherwise unstable sites. • Grade and re-vegetate as soon as feasible and use temporary covers (e.g., RECPs, polyethylene sheeting) if re-vegetation is not immediately possible. **Long Term** • Inspect and maintain EPSC measures and remove temporary measures (e.g., sediment fencing) when no longer necessary. • Monitor for successful re-vegetation.	1, 2, 4-10, 21-23

Cut and fill construction	Maintain slope stability by preventing over-steepening, prevent sediment from entering streams/waterways	**Short Term** • Prior to starting work, install sediment controls (e.g., sediment fences, berms) between construction works and waterways. • Cover bare ground at temporarily inactive sites with brush or RECPs. • Limit construction to dry weather periods when possible. • Consider end hauling in steep areas to avoid sliver fills and over steepening of slopes. **Long Term** • Conduct re-vegetation in conjunction with mulching and/or erosion mats. • Use live wattles or fascines where stabilization required. • Inspect and maintain EPSC measures.	1, 4-10, 14, 19, 21-24
Borrow sites	Prevent sediment from entering streams/waterways, maintain site stability	**Short Term** • Maximize distance from streams/waterways. • Avoid steep slopes or otherwise unstable sites. • Re-slope to stable configuration after closure. • Re-vegetate as soon as feasible and use temporary covers (e.g., RECPs, polyethylene sheeting) if re-vegetation is not immediately possible. **Long Term** • Monitor for successful re-vegetation.	1, 2, 4-12, 21-23
Construction induced slope failure	Prevent erosion and delivery of sediment into streams/waterways	**Short Term** • Consult TSFAs and geohazard risk assessments prior to beginning construction. • Conduct work in sensitive or potentially unstable areas in dry weather. • Identify seepage zones and other locations of potential failure prior to beginning construction. • Install retaining wall structures where necessary. **Long Term** • Inspect and maintain retaining walls.	1, 17, 18
Settling Basin	Prevent erosion and delivery of sediment into streams/waterways, maintain sediment removal efficiency in pond	**Short Term** • Monitor efficiency of basin. **Long Term** • Dredge basin to maintain sediment removal efficiency. • Maintain access road to basin.	

Note: For "Applicable BMP Numbers," refer to Appendix D.

6.3 NPAG QUARRY

6.3.1 Description of Works – Construction

An NPAG Quarry (area = 4 ha) will be developed in NPAG rock, about 1,600 m east of the mill building, southeast of Brucejack Lake (Figure 6.3-1), to provide construction fill as required. The quarry bedrock is volcanic porphyry and has been classified as NPAG (BGC 2014). The rock will be mined at the quarry site using conventional drill and blast methods. A crusher will be located at the quarry site. Approximately 740,000 m^3 of rock will be excavated from the quarry and hauled along existing Lakeshore Drive that follows the south shore of Brucejack Lake to the Mine Site.

Slope design parameters include an average bench face angle of 65°, a maximum bench height of 15 m, minimum bench widths ranging from 9 to 10 m, and a maximum overall height of 75 m (BGC 2014). The overall angle of the NPAG Quarry will be controlled by the bench geometry, and will be dependent on the number of benches utilized. Based on the maximum overall slope height considered, overall slope angles will range from 45 to 47°.

All surface drainage from the quarry site will be to Brucejack Lake, which will act as a settling basin, as well as providing dilution capacity. The NPAG Quarry floor will be configured to slope inward to act as a settling basin. Water will be withdrawn (pumped) from the top of this settling basin and directed downslope, where it will drain to Brucejack Lake. There is an approximate 200-m buffer between Brucejack Lake and the quarry. During periods that the NPAG Quarry is not active, the quarry floor will be allowed to fill and overtop (BGC 2015).

6.3.2 Erosion Prevention and Sediment Control – Implementation and Operation Measures

Management measures for EPSC during construction and maintenance of the NPAG Quarry are provide below. Selecting the appropriate measure is critical to achieving the management objective during a specific construction activity. Table 6.3-1 provides a summary of the expected NPAG Quarry construction activities with applicable management measures and BMPs. Some applicable BMPs may not be identified in this table and will be selected on a site-specific, as-needed basis.

Drainage during construction will be managed as follows.

- A diversion channel is not envisaged for this temporary quarry as it is deemed impractical at this rocky and steep site.
- As construction progresses, storm drainage will be managed by temporary (or permanent) swales and ditches. The drainage will be directed to current outlet drainage patterns. Basic storm water BMPs such as the installation of silt fences to prevent erosion may be employed where appropriate.
- Flows down-gradient of the site will follow existing drainage paths to Brucejack Lake, some 200 m away. As noted above, these drainage paths may be treated with storm water BMPs such as silt fences if required.

Note: For "Applicable BMP Numbers," refer to Appendix D.

6.4 GRAVEL BORROW SOURCES AT MINE SITE

Along with the NPAG Quarry, additional areas will be developed to provide an NPAG aggregate source.

These gravel borrow sources, located on southeast corner of Brucejack Lake near the NPAG Quarry (Figure 6.4-1), will be developed using a front-end loader and haul trucks. Drilling and blasting will not be required to develop these gravel sources. Gravel will be used primarily in concrete, but at times may also be used for structural backfill and road cap. Table 6.4-1 presents the location and general description of the samples taken from each site.

The gravel source was sampled and tests concluding that the gravel is NPAG.

Figure 6.4-1. Location of Gravel Borrow Sources and Test Areas

Table 6.4-1. Location and Description of Borrow Samples

Site Number	Easting NAD83	Northing NAD83	Description
BJ1	428266	6259175	1:1 sand gravel ratio; gravels are fine with a thin layer of 1/2" gravel covering the surface exposure; only 30 - 50 cm of material before hitting the water table.
BJ2	428419	6259212	1:1 sand gravel ratio; fine gravels; thin layer of 1 - 2" gravel on surface exposure, local pieces > 3"
BJ3	428454	6259321	Sand-dominated zone, 2:1 ratio; 1 – 3 m thick; 1 - 2" gravel covering the surface, with rare cobble and boulder ranging up to 1 m
BJ4	428579	6259401	1:4 sand gravel ratio; overburden is 2 – 4 m thick, cut by surrounding creeks; gravels are pea size, with 20 - 30% ½ - 1" component; surface exposure is dominated by 1 - 2" material, with lesser 3 - 4" material
BJ5	428470	6259574	Gravel dominated bed, 1:5; sands are coarser as are the gravels (typically ¼ - 1/2" size), with occasional > 3" piece picked up by the shovels (~3 per pail); this bed is 6 m thick at the south end, and only 2 m thick at the top end, as it is underlain southerly dipping outcrop, and also cut by creek in the middle; surface exposure covered by 2 - 6" material
BJ6	428743	6259585	1:4 sand gravel ratio; sands are coarse; beds are over 8m thick locally; surface exposure covered mainly by 2 - 4" material
BJ7	428573	6259295	Sand Pit; 2:1 ratio; surface exposure covered by 1/4" - 1" gravel; difficult to estimate the thickness of the bed, but it is at least 2m thick
BJ8	428486	6259042	Sandy beach, 2:1 ratio; small area to collect material from, so likely not ideal; fine sands and gravels; surface exposure covered by 1/4" gravel
BJ9	428864	6259617	Gravel with minor, coarse sands, 4:1 (gravel:sand); material 40% < 5mm, 40% 5 – 10 mm, 20% > 10mm; extensive glaciofluvial terraces cover an area ~ 200 m X 60 m; sediment thickness will vary over area

(continued)

Table 6.4-1. Location and Description of Borrow Samples (completed)

Site Number	Easting NAD83	Northing NAD83	Description
BJ10	428711	6259435	Sandy gravels, ~ 2:1 (gravel:sand); material: 50% < 5 mm, 40% 5 – 10 mm, 10% > 10 mm; extensive glaciofluvial terraces covering an area ~ 170 m X 50 m, however, till intercepted 30 – 50 cm deep within sample pit indicating that glacialfluvial sediments may only form layer over till here; thickness of glacialffluvial sediments will vary within area, intersection of till beds of varied thickness, interbedded with glacialfluvial sediments, can be expected when excavating; extensive glaciofluvial terraces covering area ~. 170 m X 60 m

6.4.1 Description of Works – Construction

The gravel processing operation required to produce concrete aggregates will involve excavation and stockpiling of natural gravel deposits. A front-end loader will feed the gravel from the stockpile into the feed hopper of a screening plant. The vibrating screens will separate the unwanted fraction of grain sizes to produce a product with the required gradation. The screen plant will also be fitted with spray bars which will wash the fine silt particles from the rock and sand as it passes through the screens. The silt-laden water will drop through the screens and be channeled to a sump which will provide retention time to allow the fines to settle. A pump will decant water from the sump and recycle it back to the screening plant. During initial start-up of the operation, water will be drawn from the lake to run the spray bars, until the sump has been filled up. Once the sump is full, only make-up water will be required to replace the water that seeps out of the sump into the underlying soils. The silt accumulating on the bottom of the sump will "blind" the underlying soils and reduce loss of water from the cycle, which will serve to minimize the required volume of make-up water. Access to the gravel borrow sources will be off the realignment of Lakeshore Drive.

Gravel will be used extensively during the Construction phase, then may be required periodically throughout Operations for road bed maintenance. Therefore, access to the gravel source will remain in place until end of mine life.

6.4.2 Erosion Control and Sediment Prevention – Implementation and Operation Measures

Management measures for erosion prevention and sedimentation control during construction and maintenance of the gravel borrow sources are provided below. Selecting the appropriate measure is critical to achieve the management objective during a specific construction activity. Table 6.4-2 provides a summary of the expected aggregate quarries construction activities with applicable management measures and BMPs. All applicable BMPs may not be identified in this table and will be selected on a site-specific, as-needed basis.

6.5 KNIPPLE TRANSFER AREA

The Knipple Transfer Area is located along the Brucejack Access Road approximately 5 km west of the Bowser Aerodrome. It is in a relatively flat terraced area located above historical flood levels of Bowser Creek. The site has been previously used as a camp. Although not generally subject to geohazards, there is some risk of snow avalanche at this site.

Table 6.4-2. Applicable Erosion Prevention and Sediment Control Best Management Practices Relevant to the Aggregate Quarries at Mine Site

Activity	Management Objectives	Management Measures	Applicable BMP Numbers
Ditches	Prevent erosion, maintain stability of ditch structures and armouring	**Short Term** • Armour with riprap, RECPs, or other means. • Use check dams to slow runoff velocity. **Long Term** • Immediately re-stabilize if disturbed by grading or other road maintenance. • Install erosion mats. • Inspect and maintain EPSC measures.	1, 4-9, 12-13, 24
Road surface erosion	Prevent erosion and delivery of sediment into streams/waterways, maintain long-term road surface stability	**Short Term** • Adhere to proper road construction guidelines, including maintaining an appropriate depth and type of surfacing material. • Use water bars as a temporary measure until ditches and culverts can be installed or repaired. **Long Term** • Grade and replace surface material as required. • Inspect and maintain EPSC measures.	2, 11, 20, 22, 24

Note: See Section 6.1 for a detailed description of road surface erosion control
Note: For "Applicable BMP Numbers," refer to Appendix D.

6.5.1 Description of Works – Construction

The Knipple Transfer Area will be located west of Knipple Lake, about 55 km by road from Highway 37 and 18 km from the Brucejack Mine Site. The Knipple Transfer Area will include a camp, maintenance and emergency vehicle building, fuel dispensing system, helipad, and laydown area as shown in Figure 6.5-1. It will occupy a development footprint of about 5 ha. All deliveries to and from the Brucejack Mine Site will report to this facility.

6.5.2 Erosion Prevention and Sediment Control – Implementation and Operation Measures

Management measures for EPSC during construction and maintenance of the Knipple Transfer Area are provided below. Selecting the appropriate measure is critical to achieve the management objective during a specific construction activity. Table 6.5-1 provides a summary of the expected construction activities with applicable management measures and BMPs. Some applicable BMPs may not be identified in this table and will be selected on a site-specific, as-needed basis.

An interception ditch will be constructed along the northern edge of the Knipple Transfer Area to direct any intercepted non-contact water toward Knipple Lake. This will help keep the construction site dry and minimize sediment loading in site drainage. The ditch will be armour protected with riprap underlain with geotextile as needed for erosion protection (BGC 2015).

Figure 6.5-1
Knipple Transfer Area Layout

PRETIVM

Table 6.5-1. Applicable Erosion Prevention and Sediment Control Best Management Practices Relevant to the Knipple Transfer Area

Activity	Management Objectives	Management Measures	Applicable BMP Numbers
Ditches	Prevent erosion, maintain stability of ditch structures and armouring	**Short Term** • Armour with vegetation, riprap, RECPs, or other means. • Use check dams to slow runoff velocity. **Long Term** • Immediately re-stabilize if disturbed by grading or other road maintenance. • Conduct re-vegetation in conjunction with mulching and/or erosion mats. • Inspect and maintain EPSC measures. • Pile snow and ice in undisturbed areas with low slopes and a minimum of 30 m from any waterway. • Minimize the amount of sediment mixed with snow and ice during snow removal and transport. • Install sediment controls (e.g., silt fences, berms) around snow piles containing a large amount of soil or organic matter.	1, 4-9, 12-13, 24
Sumps	Prevent erosion and delivery of sediment into streams/waterways, maintain sediment removal efficiency in pond	**Short Term** • Monitor efficiency of sumps and remaining freeboard to achieve efficient sediment deposition. **Long Term** • Dredge sump to maintain sediment removal efficiency • Maintain access road to basin.	

Note: For "Applicable BMP Numbers," refer to Appendix D.

Runoff from the Knipple Transfer Area development site is expected to be minimal due to its small surface extent (5.4 ha) and relatively coarse textured substrate; however, temporary water management features such as sumps and ditches will be used during construction as part of the BMPs (Table 6.5-1).

6.6 BOWSER AERODROME

Regular chartered flights will transport mine personnel to and from the Project site from the point of origin to an aerodrome to be located west of Bowser Lake. In inclement weather conditions where aircraft are unable to fly, personnel will be bused from Terrace to the Knipple Transfer Area. Transport from both the Bowser Aerodrome and Knipple Transfer Area to / from the Brucejack Mine Site will be by vehicles equipped for glacier travel.

6.6.1 *Description of Works – Construction*

The new aerodrome will be constructed at the site of a historical gravel airstrip, which will be improved and expanded to provide a safe and maintainable facility for the chartered air traffic. The Bowser Aerodrome is shown in Figure 6.6-1. A small hill about 450 m west of the proposed aerodrome maybe excavated to reduce the impacts of the hill on the take-off approach surface areas. Samples collected from the Bowser Aerodrome area were NPAG.

The runway, taxiway, and apron surface will be granular and suitable for turbo-prop aircraft. The runway will be 1,524 m long and 30 m wide. The runway will include a 7.5-m graded area along each runway edge and a 60-m-long graded area beyond each runway end. The taxiway will be constructed to a width of 18 m with a 6-m-wide graded area along each edge. The aircraft parking apron has been sized to allow two Dash 8 sized aircraft to manoeuver and park. The overall footprint of the aerodrome will be about 10 ha.

A level area will be available for helicopter landing if required.

A pre-fabricated ATCO-type trailer Air Terminal Building will be located adjacent to the apron. The Air Terminal Building will be equipped with sufficient windows to view the aerodrome and surrounding area. The building will be mounted on piles to protect it from the possibility of floods.

6.6.2 *Erosion Control and Sediment Prevention – Implementation and Operation Measures*

Management measures for EPSC during construction and maintenance of the Bowser Aerodrome are provided below. Selecting the appropriate measure is critical to achieve the management objective during a specific construction activity. Table 6.6-1 provides a summary of the expected Bowser Aerodrome construction activities with applicable management measures and BMPs to meet these objectives. Some applicable BMPs may not be identified in this table and will be selected on a site-specific, as-needed basis.

Permanent drainage ditches will be located along the north and south sides of the runway, and will drain at approximately 0.5% grade to the river (BGC 2015).

Drainage during construction will be managed as follows.

- For the main runway / apron site, the ditches on the north and south sides of the runway will be installed. This will help keep the construction site dry and minimize sediment loading in site drainage, though as above this site generally drains rapidly to ground.
- For water flowing down-gradient of the runway ditches, the water may follow its existing drainage paths to the Bowser River.
- As earthworks construction progresses through the aerodrome site, the storm drainage will be managed by swales, ditches, and sumps.

Figure 6.6-1
Bowser Aerodrome

PRETIVM

Table 6.6-1. Applicable Erosion Control and Sediment Prevention Best Management Practices Relevant to the Bowser Aerodrome

Activity	Management Objectives	Management Measures	Applicable BMP Numbers
Overland floodplains and alluvial fans	Prevent erosion of slopes in floodplains, fans and, on sensitive soils	**Short Term** • Avoid construction in sensitive soils whenever feasible. • If construction in sensitive soils is required, cover bare ground at temporarily inactive sites with brush or RECPs. • Install armour/riprap along fills. • Limit construction to dry weather periods when feasible. **Long Term** • Conduct re-vegetation in conjunction with mulching and/or erosion mats. • Use live wattles or fascines where stabilization required. • Inspect and maintain EPSC measures.	1, 4-10, 14, 21-24
Ditches	Prevent erosion, maintain stability of ditch structures and armouring	**Short Term** • Armour with vegetation, riprap, RECPs, or other means. • Use check dams to slow runoff velocity. **Long Term** • Immediately re-stabilize if disturbed by grading or other road maintenance. • Conduct re-vegetation in conjunction with mulching and/or erosion mats. • Inspect and maintain EPSC measures.	1, 4-10, 13-14, 16, 17, 20-22, 24
Spoil sites	Prevent sediment from entering streams/waterways, maintain long-term site stability	**Short Term** • Install perimeter sediment control (e.g., berms, sediment fencing) around soil disposal sites. • Maximize distance from streams/waterways. • Avoid steep slopes or otherwise unstable sites. • Re-vegetate as soon as feasible and use temporary covers (e.g., RECPs, polyethylene sheeting) if re-vegetation is not immediately feasible. **Long Term** • Inspect and maintain EPSC measures and remove temporary measures (e.g., sediment fencing) when no longer necessary. • Monitor for successful re-vegetation.	1, 2, 4-10, 21-23

(continued)

Table 6.6-1. Applicable Erosion Control and Sediment Prevention Best Management Practices Relevant to the Bowser Aerodrome (completed)

Activity	Management Objectives	Management Measures	Applicable BMP Numbers
Runway and road surface erosion	Prevent erosion and delivery of sediment into streams/waterways, maintain long-term road surface stability	**Short Term** • Adhere to proper road construction guidelines, including maintaining an appropriate depth and type of surfacing material. • Use water bars as a temporary measure until ditches and culverts can be installed or repaired. **Long Term** • Grade and replace surface material as required. • Inspect and maintain EPSC measures.	11, 17-18, 20, 22, 24
Snow handling	Prevent delivery of fine sediment from meltwater to streams/waterways	**Short Term** • Pile snow in undisturbed areas with low slopes a minimum of 30 m from any waterway. • Minimize the amount of sediment mixed with snow during snow removal and transport, where feasible. • Install sediment controls (e.g., silt fences, berms) around snow piles containing a large amount of soil or organic matter.	1, 21-24
Concrete Placement	Prevent erosion and delivery of sediment into streams/waterways	**Short Term** • Control runoff from the in and out of the area through the use of sediment fencing, berms and ditches. • Control runoff from the in and out of the area through the use of sediment fencing, berms and ditches.	11, 21 22, 24
Settling Basins and Sumps	Prevent erosion and delivery of sediment into streams/waterways, maintain sediment removal efficiency in basin/sump	**Short Term** • Monitor efficiency of basin/sump **Long Term** • Dredge basin to maintain sediment removal efficiency • Maintain access road to basin/sump	

Note: See Section 6.1 for a detailed description of runway and road surface erosion control
Note: For "Applicable BMP Numbers," refer to Appendix D.

The drainage at the excavation to remove the high ground within the west approach will follow storm water BMPs. This will include diverting drainage around the site if required, and use of other BMPs.

6.7 BOWSER CAMP

The existing Bowser Camp includes a kitchen and dormitories, and can accommodate 30 people.

6.7.1 Description of Works – Construction

An area will be cleared at the existing Bowser Camp to accommodate a temporary 100-man camp to support construction of the Brucejack Transmission Line and a laydown area. Figure 6.7-1 shows this area in relation to the Bowser Aerodrome.

Figure 6.7-1
Bowser Camp Arrangement

PRETIVM

6.7.2 Erosion Prevention and Sediment Control – Implementation and Operation Measures

Management measures for EPSC during construction and maintenance of the Bowser Camp are provided below. Selecting the appropriate measure is critical to achieve the management objective during a specific construction activity. Table 6.7-1 provides a summary of the expected Bowser Camp construction activities with applicable measures and BMPs. Some applicable BMPs may not be identified in this table and will be selected on a site-specific basis.

Table 6.7-1. Applicable Erosion Prevention and Sediment Control Best Management Practices Relevant to Bowser Camp

Activity	Management Objectives	Management Measures	Applicable BMP Numbers
Cut and fill construction	Maintain slope stability by preventing over-steepening, prevent sediment from entering streams/waterways	**Short Term** • Prior to starting work, install sediment controls (e.g., sediment fences, berms) between construction works and waterways. • Cover bare ground at temporarily inactive sites with brush or RECPs. • Limit construction to dry weather periods when feasible. • Consider end hauling in steep areas to avoid sliver fills and over steepening of slopes. **Long Term** • Conduct re-vegetation in conjunction with mulching and/or erosion mats. • Use live wattles or fascines where stabilization required. • Inspect and maintain EPSC measures.	1, 4-10, 14, 19, 21-24
Spoil sites	Prevent sediment from entering streams/waterways, maintain long-term site stability	**Short Term** • Install perimeter sediment control (e.g., berms, sediment fencing) around soil disposal sites. • Maximize distance from streams/waterways. • Avoid steep slopes or otherwise unstable sites. • Re-vegetate as soon as feasible and use temporary covers (e.g., RECPs, polyethylene sheeting) if re-vegetation is not immediately feasible. **Long Term** • Inspect and maintain EPSC measures and remove temporary measures (e.g., sediment fencing) when no longer necessary. • Monitor for successful re-vegetation.	1, 2, 4-10, 21-23

(continued)

Table 6.7-1. Applicable Erosion Prevention and Sediment Control Best Management Practices Relevant to Bowser Camp (completed)

Activity	Management Objectives	Management Measures	Applicable BMP Numbers
Ditches	Prevent erosion, maintain stability of ditch structures and armouring	**Short Term** • Armour with vegetation, riprap, RECPs, or other means. • Use check dams to slow runoff velocity. **Long Term** • Immediately re-stabilize if disturbed by grading or other road maintenance. • Conduct re-vegetation in conjunction with mulching and/or erosion mats. • Inspect and maintain EPSC measures.	1, 4-9, 12-13, 24
Road surface erosion	Prevent erosion and delivery of sediment into streams/waterways, maintain long-term road surface stability	**Short Term** • Adhere to proper road construction guidelines, including maintaining an appropriate depth and type of surfacing material. • Use water bars as a temporary measure until ditches and culverts can be installed or repaired. **Long Term** • Grade and replace surface material as required. • Inspect and maintain EPSC measures.	2, 11, 20, 22, 24
Construction in sensitive soils	Prevent erosion and delivery of sediment into streams/waterways	**Short Term** • Prior to starting work, install sediment controls (e.g., sediment fences, berms) between construction works and waterways. • Cover bare ground at temporarily inactive sites with brush or RECPs. • Remove veneers from bedrock within road prism to remove likelihood of erosion. • Limit construction to dry weather periods when feasible. **Long Term** • Conduct re-vegetation in conjunction with mulching and/or erosion mats. • Use live wattles or fascines where stabilization required. • Inspect and maintain EPSC measures.	1, 4-12, 14, 21-24
Snow handling	Prevent delivery of fine sediment from meltwater to streams/waterways	**Short Term** • Pile snow in undisturbed areas with low slopes a minimum of 30 m from any waterway. • Minimize the amount of sediment mixed with snow during snow removal and transport, where feasible. • Install sediment controls (e.g., silt fences, berms) around snow piles containing a large amount of soil or organic matter.	1, 21-24

Note: See Section 6.1 for a detailed description of road surface erosion control
Note: For "Applicable BMP Numbers," refer to Appendix D.

6.8 BRUCEJACK TRANSMISSION LINE

The Brucejack Transmission Line alignment will follow bedrock-dominated terrain that is characterized by gentle to moderate slopes, bedrock hummocks, and discrete debris flow/snow avalanche tracks.

6.8.1 Description of Works – Construction

The overall power requirements for the Project will be approximately 20 megawatts. The Project will be powered by electricity from the BC Hydro grid. The proposed transmission line route is from the Long Lake Hydro Substation to the Mine Site (Figure 6.8-1).

Starting at the Long Lake transmission line west of the Hydro Substation, the Brucejack Transmission Line will follow the bedrock slopes on the east side of the Salmon Glacier to the terminus of the Knipple Glacier. From the Knipple Glacier, the preferred transmission line route will generally follow the upper crest of the bedrock slope south of the glacier to the Mine Site. Large towers will facilitate spanning the snowfields in the area.

No new roads are anticipated to be required to support construction of the Brucejack Transmission Line. The Granduc Access Road and existing mineral exploration trails will provide access and staging areas for much of the southern portion of the alignment. Staging for portions of the alignment north of the Granduc mill site will be from the Tide Staging Area, Bowser Camp laydown, and the Knipple Transfer Area. Tower emplacement and conductor stringing will be conducted by helicopter.

6.8.1.1 Tide Staging Area

The Tide Staging Area is located near the site of the historical Granduc Mine and airstrip. It is a relatively small area which will further be cleared to increase the size for use as a short-term staging area for equipment and materials associated with the construction of the Brucejack Transmission Line.

6.8.2 Erosion Control and Sediment Prevention – Implementation and Operation Measures

Management measures for EPSC during construction and maintenance of the Brucejack Transmission Line are provided below. Selecting the appropriate measure is critical to achieve the management objective during a specific construction activity. Table 6.8-1 provides a summary of the expected Brucejack Transmission Line construction activities with applicable management measures and BMPs. Some applicable BMPs may not be identified in this table and will be selected on a site-specific, as-needed basis. BMPs specific to riparian protection can be found in Appendix B.

Brucejack Transmission Line construction is anticipated to have minimal implications for water management as construction by use of helicopters rather than by use of land vehicles is planned. Should there be a need to work in and around water during construction of the Brucejack Transmission Line, Section 6.1 – Brucejack Access Road, will be referred to for direction regarding EPSC.

Table 6.8-1. Applicable Erosion Prevention and Sediment Control Best Management Practices Relevant to the Transmission Line

Activity	Management Objectives	Management Measures	Applicable BMP Numbers
Road surface erosion	Prevent erosion and delivery of sediment into streams/waterways, maintain long-term road surface stability	**Short Term** • Monitoring of road surface erosion to be done and response coordinated with operators of Granduc Road. • Adhere to proper road construction guidelines for any necessary upgrades, including maintaining an appropriate depth and type of surfacing material.	2, 11, 20, 22, 24
Clearing	Prevent erosion and delivery of sediment into streams/waterways, maintain long-term site stability	**Short Term** • Minimize removal of vegetation and disturbance to soil (leave in place) to extent possible, yet still meets engineered design specs. • Install perimeter sediment control (e.g., berms, sediment fencing) around clearing site as needed. **Long Term** • Inspect and maintain EPSC measures and remove temporary measures (e.g., sediment fencing) when no longer necessary. • Monitor for successful re-vegetation and soil.	1, 2, 4-10, 21-23
Stream crossings	Prevent sediment from entering streams/waterways	**Short Term** • Prior to starting work, install sediment controls (e.g., sediment fences, berms) between construction works and waterways. • Minimize disturbance to riparian vegetation. • Limit construction to dry weather periods when feasible. • Use armour/riprap in areas where bank erosion is likely. • Inspect EPSC measures after any runoff-producing rain event. **Long Term** • Conduct re-vegetation in conjunction with mulching and/or erosion mats. • Use live wattles or fascines where bank stabilization required. • Inspect and maintain EPSC measures and remove temporary measures (e.g., sediment fencing) when they are no longer necessary.	1, 4-10, 14, 16-19, 21-24

(continued)

Table 6.8-1. Applicable Erosion Prevention and Sediment Control Best Management Practices Relevant to the Transmission Line (continued)

Activity	Management Objectives	Management Measures	Applicable BMP Numbers
Construction in sensitive soils	Prevent erosion and delivery of sediment into streams/waterways	**Short Term** • Prior to starting work, install sediment controls (e.g., sediment fences, berms) between construction works and waterways. • Cover bare ground at temporarily inactive sites with brush or RECPs. • Remove veneers from bedrock within road prism to remove likelihood of erosion. • Limit construction to dry weather periods when feasible. • Consider end hauling in steep areas to avoid sliver fills and over steepening of slopes. **Long Term** • Conduct re-vegetation in conjunction with mulching and/or erosion mats. • Use live wattles or fascines where stabilization required. • Inspect and maintain EPSC measures.	1, 4-12, 14, 21-24
Equipment and Staging Areas	Prevent erosion and delivery of sediment into streams/waterways	**Short Term** • Minimize the footprint and install sediment controls (e.g., sediment fences, berms) between staging site and waterways. • Avoid steep slopes or otherwise unstable sites. • Grade traffic area and maintain berms and ditches. **Long Term** • Re-vegetate as soon as feasible and use temporary covers (e.g., RECPs, polyethylene sheeting) if re-vegetation is not immediately feasible.	1, 2, 4-12, 21-24
Steep Slopes	Prevent erosion and delivery of sediment into streams/waterways	**Short Term** • Avoid constructing or exposing very steep slopes. Create slope breaks through terracing and add texture on slopes where feasible. • Stabilize slopes (is. live wattles/fascines, RECPs, riprap armouring, gabions, retaining walls). • Maintain proper drainage through the use of slope drains. Construct cross drains and ditches if necessary. **Long Term** • Re-vegetate as soon as feasible and use temporary covers (e.g., RECPs, polyethylene sheeting) if re-vegetation is not immediately feasible.	1-12, 14-15, 17-20

(continued)

Activity	Management Objectives	Management Measures	Applicable BMP Numbers
Anchor Drilling	Prevent erosion and delivery of sediment into streams/waterways	**Short Term** • Prior to starting work, install sediment controls (e.g., sediment fences, berms) between construction works and waterways. **Long Term** • Re-vegetate as soon as feasible and use temporary covers (e.g., RECPs, polyethylene sheeting) if re-vegetation is not immediately feasible.	1, 4-12, 21-24
Concrete Placement	Prevent erosion and delivery of sediment into streams/waterways	**Short Term** • Control runoff from the in and out of the area through the use of sediment fencing, berms and ditches to contain concrete wash.	11, 21 22, 24

Note: See Section 6.1 for a detailed description of road surface erosion control
Note: For "Applicable BMP Numbers," refer to Appendix D.

7 ENVIRONMENTAL MONITORING

An Erosion Prevention and Sediment Control Monitoring Program will be implemented at the initiation of construction activities. The monitoring program will focus on inspection and maintenance of structures related to EPSC management, with an emphasis on adaptive management to quickly evaluate and respond to changing conditions and requirements. The key objectives of the Erosion Prevention and Sediment Control Monitoring Program are:

- to assess the performance of water management structures and systems; and
- to identify and promptly address areas where maintenance, upgrades, modifications, or additional mitigation measures are necessary.

The following plans have additional mitigation and management measures relevant to EPSC:

- Aquatic Effects Monitoring Plan;
- Vegetation Management Plan;
- Emergency Response Plan;
- Traffic Management Plan; and
- Water Management Plan.

The Environmental Manager will be responsible for overseeing the Erosion Prevention and Sediment Control Monitoring Program, maintaining inspection and maintenance records, ensuring monitoring reporting, and providing guidance on any modifications to the program.

7.1 PERFORMANCE MONITORING

Trained environmental personnel will be employed as Environmental Monitors and Technicians. The environmental personnel will inspect, evaluate, and report on the effectiveness of EPSC management strategies and mitigation measures, with respect to regulatory permits, approvals, and authorizations. Under the supervision of the Environmental Manager, the environmental personnel will have the responsibility of confirming that EPSC measures are properly implemented. The Environmental Manager, along with others, will have the authority to stop work if conditions are not met or if, in their technical opinion, the continuation of work will lead to non-compliance. Site workers will report incidents that may result in erosion, structural or functional failure, culvert debris accumulation, or similar occurrences to the Environmental Department.

Site personnel will be encouraged to communicate any concerns related to erosion and sedimentation, improper site drainage, contaminant releases, and debris or snow jams in drainage-ways and at stream crossings to their supervisor.

The Environmental Monitors and Construction Management Team, where appropriate, will conduct visual inspections and assessments of EPSC structures on an ongoing basis as part of general site management. On active work sites, these informal visual inspections will be augmented by formal, regularly scheduled inspections to be performed by Environmental Monitors such that each site is visited on a monthly basis or more often as dictated by site conditions. In frozen conditions, formal inspection frequency may be reduced. Inspections of all sites will be conducted within 24 hours of rainfall events greater than 100 mm in a 24-hour period as per the Water Management Plan.

EPSC structures will be maintained during construction by the Contractor. Maintenance procedures will include prompt attention to potential ditch or culvert blockage or failure, or outside seepage, because such problems could lead to structure failure and sediment transport. Maintenance will also include routine removal of accumulated sediment from ditches and retention structures.

EPSC monitoring variables and their monitoring frequency are outlined in Table 7.1-1. Monitoring frequency may be increased based on the results of the Aquatic Effects Monitoring Plan and other relevant monitoring results. Inspection criteria may be modified on a site-by-site basis or as conditions require.

Table 7.1-1. Erosion Prevention and Sediment Control Monitoring Variables, Frequency, and Expected Targets

Monitoring Variable	Monitoring Frequency	Targets
Performance of EPSC structures and systems (e.g., diversion ditches, sumps)	Monthly[1] or after high rainfall/runoff[2] events	Functioning as intended
Site and Brucejack Access Road drainages	Monthly[1] or after high rainfall/runoff[2] events	Positive drainage maintained at all times; no ponding
Inventory of on-site supply of EPSC materials	Ongoing[3]	Sufficient supply is always available on site

[1]*Frequency may be decreased during winter when ground is frozen*
[2]*Combined rainfall and snowmelt runoff events (rain-on-snow events) pose the most significant risk to water management structures and systems. Surveys of EPSC structures prior to winter break-up are required to assess functionality and potential maintenance requirements (e.g., removal of excess snow/ice from ditches and basins, repair or replacement of blocked/frozen culverts and pipes).*
[3]*Materials will be replaced immediately after use, if identified by the Construction Management Team as necessary. Inventory checked at a minimum of monthly.*

7.2 WATER QUALITY (TOTAL SUSPENDED SOLIDS, TOTAL DISSOLVED SOLIDS, AND TURBIDITY MANAGEMENT)

The BC Ministry of Environment's Environmental Protection Division administers the *Environmental Management Act* (2003) by setting criteria to define when "sediment yield" becomes a "pollutant" (Clark et al. 2012). Provincial water quality guideline documents provide targets of acceptable levels of sediment in water that are typically used when determining the performance of control measures when undertaking in-stream works and works that may result in a sediment release to a water course (*Ambient Water Quality Guidelines (Criteria) for Turbidity, Suspended and Benthic Sediments;* BC MOE 2001).

The hydrological regime is an important determinant of water quality in the Project area. Typically local streams experience a low flow period between November and April. Higher flows typically occur between May and October associated with freshet, summer glacial melt, and fall heavy rain events. The hydrological regime affects water quality in two ways: 1) increased discharge during freshet, glacial melt, and heavy rainfall events dilutes concentrations of total dissolved solids; and 2) increased sediment load and transport during high flow periods leads to increased concentrations of TSS.

Embankment condition and evidence of sediment transport into watercourses will be assessed at, for example, water diversion channels, drainage ditches, pools, and waterway crossings along roads. The waterbodies adjacent to construction sites will be visually inspected for introduced sediment. Water sampling and/or turbidity testing may also be carried out if discolouration occurs. Regular inspection of areas releasing sediment will be carried out until sediment is no longer released.

Any sites determined to require ongoing monitoring will document, as appropriate, GPS coordinates, erosion type, rainfall intensity, and the extent of the affected area, as well as existing control measures and assessment of their performance. Identified sites will be regularly checked for ongoing evidence of erosion, particularly after high rainfall events, until erosion is no longer a concern. Targeted field measurements, such as turbidity, will be taken as appropriate. Monitoring results may be used to trigger an appropriate adaptive management response.

7.3 CONTINGENCY RESPONSES

In the event that TSS concentrations exceed the BCWQGs or measured background levels, taken upstream of the discharge point at the time of discharge, the Environmental Monitor will immediately stop related work and notify the Environmental Coordinator. The Environmental Coordinator, in consultation with the Mine Manager, will have the authority to require that other mitigation and emergency sediment control measures be carried out depending on the severity of the situation.

A supply of environmental contingency material and equipment will be available on site as described in Section 5.1.3.

During and after an exceedance event, additional turbidity and TSS samples will be taken at key locations, including the entry point to the affected waterway and the corresponding background site until conditions return to baseline or within the BCWQG. Exceedances require the completion of an environmental incident report (described in Section 8.1).

8 REPORTING AND RECORDING

8.1 REPORTING

8.1.1 Compliance Reporting (As per Permit Conditions)

The Environmental Manager will ultimately be responsible for reporting on observations and monitoring results (Table 8.1-1). Reporting of environmental monitoring data will be conducted in accordance with permit and approval conditions. Regulatory requirements are anticipated to entail formal annual reports, including disclosure of issues of non-compliance.

Table 8.1-1. Erosion Prevention and Sediment Control Reporting Requirements, Frequency, and Responsibilities

Report Type	Frequency	Reporting Responsibilities	Submitted to
Annual report	Annually	Environmental Manager	Mine Manager, regulatory authorities
Environmental incident report	As soon as feasible after occurrence	Initial notification by attending manager	Environmental Manager, regulatory authorities

8.1.2 Internal Reporting

The Environmental Monitor will document all site inspections, field observations, and photos using a Daily Monitoring Form (Appendix F). Information recorded will include the work site, time, date, weather conditions, current site activity, list of water management practices or structures being utilized, key observations (challenges and successes), incidents or non-compliance issues, plus any follow-up that was implemented. This information will be summarized into a weekly (Appendix G) and, if required, monthly internal Environmental Monitoring Summary report.

Any formal documents and reports will follow version-control procedures to ensure they are approved before use and the internal and external users are accessing the most current information.

8.1.3 Incident Reporting

Environmental incidents will be communicated by the individual who detects an incident to their supervisor and to the Environmental Coordinator.

Incident and non-compliance reports will be prepared by the Environmental Monitor for distribution to the Project management and any applicable regulatory agencies. An example of an incident report is provided in Appendix H showing the nature and type of data that will be recorded. Key information includes:

- location, cause, and nature of the incident;
- environmental or Project features affected (e.g., road, watercourse, forest land, infrastructure) ;

- time, extent, and magnitude/quantity of material or area affected;
- response and actions to control the incident;
- any follow-up tasks required, mitigation/remediation/corrective actions, or additional sampling needs;
- notifications of the incident and communication within and outside the Project Team; and
- photographs, GPS location, and a map may be included for clarification and understanding of proximity risks.

Environmental incidents during construction can be grouped into two categories based upon impact magnitude and complexity. Minor incidents have no permanent or long-term impact on the environment and are generally small scale in nature with simple remedies. Major environmental incidents are infrequent; can have widespread, permanent, or lethal/toxic impacts; are complex to resolve; and may require extensive remediation or cleanup resources.

Minor incidents with little consequence to the environment will be reported within 24 hours to the Environmental Monitor. Examples of minor incidents include non-compliance with recommended Standard Operating Procedures, lack of spill cleanup equipment, and non-compliance with flagging of sensitive areas. Cleanup and remediation of the incident will be performed by the Contractor, in consultation with the Environmental Monitor, to address the causes, potential impacts, and long-term risks. The Environmental Monitor, with the assistance of the Contractor's Supervisors, will complete an Environmental Incident Report Form (Appendix H) within 48 hours, detailing the root causes, consequence(s), impacts, remediation approach, corrective recommendations, and any photos or maps. The Contractor's Environmental Manager, Environmental Monitor, and Site Supervisor will review and sign-off on the incident report and provide copies to the Engineering Procurement and Construction Manager (EPCM)/Owner's Environmental Manager with 48 hours. Minor issues are generally expected to be resolved immediately and generally no follow-up is required once addressed.

Major incidents are those with the potential to cause permanent, widespread, lethal, or cumulative impacts; a pollution release to the environment; a contravention of legislation and/or permit conditions; or a risk to human health and safety. These incidents are rare, but are more complex and resource intensive to remediate than minor incidents. Examples of major incidents include a major sediment release into a stream and damage to fish habitat or critical wildlife habitat.

Major incidents must be reported immediately to the Environmental Monitor and upward to the Mine Manager. The Mine Manager will contact applicable regulatory agencies. The Contractor must immediately respond to control, contain, and minimize any impact on the environment or risk to people. The Environmental Incident Report Form (Appendix H) will be completed, within the same day as the occurrence, by the Environmental Monitor with the assistance of the Contractor's Supervisor. The Environmental Incident Report Form will detail the root causes, consequence, impacts, and remediation approach for the incident, as well as any recommendations, photos, or maps.

The Environmental Monitor, EPCM representative, and Pretivm's Construction and Environmental Managers will conduct an immediate investigation and site visit to prepare a Major Incident Report

and provide copies to the EPCM and Pretivm management within 24 hours. External agency and First Nation/stakeholder notification may be required and will be conducted by the Mine Manager. Control of a major incident may require assistance from external agencies (e.g., sediment discharge into a sensitive area), in which case Pretivm will coordinate the response. Extensive follow-up, sampling of the environment, and remediation may be required during or after a major incident.

8.2 RECORD KEEPING / TRACKING

8.2.1 Monitoring Results

Environmental Monitors will maintain a daily log of site conditions, construction and mitigation activities, turbidity and TSS readings, upcoming activities and issues, and any other relevant communications and observations on compliance. Any incidents, unusual occurrences, or sampling results will be documented. The information compiled in the daily log will be supplemented with photographs and GPS waypoints as necessary.

Environmental Monitors will record, transcribe, and store all field data, photographs, and results from lab analyses in an information management system.

8.2.2 Audits Results

Any audit findings resulting from government site visits or communications from external agencies will be shared with the contractors to promote compliance and continuous improvement.

8.2.3 Continuous Improvement, Follow-up, and Adaptive Management

Adaptive management is a process for continually improving management practices by learning from the outcomes of operational approaches (e.g., Bunnell et al. 2009; BC MOF 2013). To be effectively implemented, it will require a prompt response to field observations of changing environmental conditions and limitations or deficiencies in existing water management structures. Adaptive management is therefore an ongoing process of monitoring, maintenance, and reassessment.

Adaptive management enables a cost- and time-effective hierarchical response to potential environmental issues when properly implemented. If the results of monitoring indicate that management measures are not adequately meeting performance objectives, the inadequacies will be promptly identified and addressed. The adaptive management approach promotes proactive measures, with the caveat that contingency plans and materials will be in place prior to the initiation of work so that additional measures can be quickly implemented if needed.

8.2.4 Documentation Responsibilities

Documents generated by the Environmental Monitor during planning and construction will include daily inspection forms, weekly/monthly summary reports, field sampling forms, incident reports, and stop work orders. Contractors will be expected to contribute factual information and review

relevant documents produced by the Environmental Monitor and, if discrepancies are found, work to clarify facts.

Contractors will provide their staff with appropriate construction documentation (designs, drawings, maps, contract specifications, environmental plans, etc.) to ensure work is appropriately planned and executed. Contractors will be responsible for documenting, photographing any environmental mitigation activities/plans, field visits, field fit plans, spill response, Requests for Information, environmental observations, and communications with the Project Team around environmental incidents, mitigation, and planning. Contractors will be expected to share environmental information, plans, and construction schedules with the Project Team and Environmental Monitor to implement effective compliance assessment, coordination, and problem solving. Contractors must keep accurate records of the location and nature of any incidents, non-compliance events, responses and mitigation measures implemented, as well as photo documentation of works adjacent to environmentally sensitive areas (e.g., culvert/bridge installations, clearing along buffers, spill cleanup, incidents) in the event an Environmental Monitor is not on site to observe work.

DFO Operational Statement for Overhead Line Construction

OVERHEAD LINE CONSTRUCTION

Fisheries and Oceans Canada
Ontario Operational Statement

Version 3.0

Overhead lines are constructed for electrical or telecommunication transmission across many watercourses that range in size from small streams and ponds to large rivers, lakes and reservoirs. This Operational Statement applies to selective removal of vegetation along the right-of-way to provide for installation and safe operation of overhead lines, and passage of equipment and materials across the water body.

Although fish habitat occurs throughout a water system, it is the riparian habitat that is most sensitive to overhead line construction. Riparian vegetation occurs adjacent to the watercourse and directly contributes to fish habitat by providing shade, cover, and spawning and food production areas. It is important to design and build your overhead line project to meet your needs while also protecting riparian areas. Potential impacts to fish and fish habitat include excessive loss of riparian vegetation, erosion and sedimentation resulting from bank disturbance and loss of plant root systems, rutting and compaction of stream substrate at crossing sites, and disruption of sensitive fish life stages.

Fisheries and Oceans Canada (DFO) is responsible for protecting fish and fish habitat across Canada. Under the *Fisheries Act* no one may carry out a work or undertaking that will cause the harmful alteration, disruption or destruction (HADD) of fish habitat unless it has been authorized by DFO. By following the conditions and measures set out below you will be in compliance with subsection 35(1) of the *Fisheries Act*.

The purpose of this Operational Statement is to describe the conditions under which it is applicable to your project and the measures to incorporate into your project in order to avoid negative impacts to fish habitat. You may proceed with your overhead line project without a DFO review when you meet the following conditions:

- it does not require the construction or placement of any temporary or permanent structures (e.g. islands, poles, crib works, etc.) below the ordinary high water mark (HWM) (see definition below), and
- you incorporate the *Measures to Protect Fish and Fish Habitat when Constructing Overhead Lines* listed below in this Operational Statement.

If you cannot meet all of the conditions listed above and cannot incorporate all of the measures listed below then your project may result in a violation of subsection 35(1) of the *Fisheries Act* and you could be subject to enforcement action. In this case, you should contact your Conservation Authority, or the DFO office in your area (see Ontario DFO office list) or Parks Canada if the project is located within its jurisdiction, including the Trent-Severn Waterway and the Rideau Canal, if you wish to obtain an opinion on the possible options you should consider to avoid contravention of the *Fisheries Act.*

You are required to respect all municipal, provincial or federal legislation that applies to the work being carried out in relation to this Operational Statement. The activities undertaken in this Operational Statement must also comply with the *Species at Risk Act* (**www.sararegistry.gc.ca**). If you have questions regarding this Operational Statement, please contact one of the agencies listed above.

We ask that you notify DFO, preferably 10 working days before starting your work by filling out and sending the Ontario Operational Statement notification form (**www.dfo-mpo.gc.ca/regions/central/habitat/os-eo/prov-terr/index_e.htm**) to the DFO office in your area. This information is requested in order to evaluate the effectiveness of the work carried out in relation to this Operational Statement.

Measures to Protect Fish and Fish Habitat when Constructing Overhead Lines

1. Installing overhead lines under frozen conditions is preferable in all situations. On wet terrains (e.g., bogs), lines should be installed under frozen conditions, where possible, or using aerial methods (i.e., helicopter).

2. Design and construct approaches so that they are perpendicular to the watercourse wherever possible to minimize loss or disturbance to riparian vegetation.

3. Avoid building structures on meander bends, braided streams, alluvial fans, active floodplains or any other area that is inherently unstable and may result in erosion and scouring of the stream bed or overhead line structures.

3.1. Wherever possible, locate all temporary or permanent structures, such as poles, sufficiently above the HWM to prevent erosion.

4. While this Operational Statement does not cover the clearing of riparian vegetation, the removal of select plants may be necessary to accommodate the overhead line. This removal

should be kept to a minimum and within the road or utility right-of-way.

5. Machinery fording the watercourse to bring equipment required for construction to the opposite side is limited to a one-time event (over and back) and should occur only if an existing crossing at another location is not available or practical to use. A *Temporary Stream Crossing* Operational Statement is also available.

- **5.1.** If minor rutting is likely to occur, stream bank and bed protection methods (e.g., swamp mats, pads) should be used provided they do not constrict flows or block fish passage.
- **5.2.** Grading of the stream banks for the approaches should not occur.
- **5.3.** If the stream bed and banks are steep and highly erodible (e.g., dominated by organic materials and silts) and erosion and degradation is likely to occur as a result of equipment fording, then a temporary crossing structure or other practice should be used to protect these areas.
- **5.4.** Time the one-time fording to prevent disruption to sensitive fish life stages by adhering to appropriate fisheries timing windows (see the *Ontario In-Water Construction Timing Windows*).
- **5.5.** Fording should occur under low flow conditions and not when flows are elevated due to local rain events or seasonal flooding.

6. Operate machinery on land and in a manner that minimizes disturbance to the banks of the watercourse.

- **6.1.** Machinery is to arrive on site in a clean condition and is to be maintained free of fluid leaks.
- **6.2.** Wash, refuel and service machinery and store fuel and other materials for the machinery away from the water to prevent any deleterious substance from entering the water.
- **6.3.** Keep an emergency spill kit on site in case of fluid leaks or spills from machinery.
- **6.4.** Restore banks to original condition if any disturbance occurs.

7. Install effective sediment and erosion control measures before starting work to prevent entry of sediment into the watercourse. Inspect them regularly during the course of construction and make all necessary repairs if any damage occurs.

- **7.1.** Avoid work during wet, rainy conditions or use alternative techniques such as aerial methods (i.e., helicopter) to install overhead lines.

8. Stabilize any waste materials removed from the work site to prevent them from entering the watercourse. This could include covering spoil piles with biodegradable mats or tarps or planting them with grass or shrubs.

9. Vegetate any disturbed areas by planting and seeding preferably with native trees, shrubs or grasses and cover such areas with mulch to prevent erosion and to help seeds germinate. If there is insufficient time remaining in the growing season, the site should be stabilized (e.g., cover exposed areas with erosion control blankets to keep the soil in place and prevent erosion) and vegetated the following spring.

- **9.1.** Maintain effective sediment and erosion control measures until re-vegetation of disturbed areas is achieved.

Definition:

Ordinary high water mark (HWM) – The usual or average level to which a body of water rises at its highest point and remains for sufficient time so as to change the characteristics of the land. In flowing waters (rivers, streams) this refers to the "active channel/bank-full level" which is often the 1:2 year flood flow return level. In inland lakes, wetlands or marine environments it refers to those parts of the water body bed and banks that are frequently flooded by water so as to leave a mark on the land and where the natural vegetation changes from predominately aquatic vegetation to terrestrial vegetation (excepting water tolerant species). For reservoirs this refers to normal high operating levels (Full Supply Level).

For the Great Lakes this refers to the 80th percentile elevation above chart datum as described in DFO's *Fish Habitat and Determining the High Water Mark on Lakes*.

Appendix B

DFO Operational Statement for Maintenance of Riparian Vegetation in Existing Rights-of-Way

MAINTENANCE OF RIPARIAN VEGETATION IN EXISTING RIGHTS-OF-WAY

Fisheries and Oceans Canada
Pacific Region Operational Statement

Version 3.0

Rights-of-way are areas of land devoted to providing transportation corridors (e.g., highways, railways) or utilities (e.g., pipelines, power lines, water lines) that often intersect waterways. Vegetation is closely managed in these areas to prevent disruption to transportation or utilities (e.g., circuit outages, fires) and to ensure personal safety. Maintenance activities involving the removal or alteration of riparian vegetation in the right-of-way corridor may negatively affect fish habitat when improperly executed. This Operational Statement applies only to existing rights-of-way at the location where they intersect and cross a water body.

Riparian areas are the vegetated areas adjacent to a water body and directly contribute to fish habitat by providing shade, cover and food production areas. Riparian areas are also important because they stabilize stream banks and shorelines. In order to minimize disturbance to fish habitat and prevent bank erosion, it is important to retain as much riparian vegetation as possible, especially the vegetation directly adjacent to the watercourse, in the right-of-way corridor.

Activities carried out to maintain riparian vegetation in existing rights-of-way can negatively impact fish and fish habitat by causing excessive loss of riparian vegetation, erosion and sedimentation, disturbance to the banks and the bottom of the water body from use of heavy equipment, and introduction of deleterious substances as a result of inadequate containment of spoil piles and improper maintenance of equipment.

Fisheries and Oceans Canada (DFO) is responsible for protecting fish and fish habitat across Canada. Under the *Fisheries Act* no one may carry out a work or undertaking that will cause the harmful alteration, disruption or destruction (HADD) of fish habitat unless it has been authorized by DFO. By following the conditions and measures set out below you will be in compliance with subsection 35(1) of the *Fisheries Act*.

The purpose of this Operational Statement is to describe the conditions under which it is applicable to your project and the measures to be incorporated into your project in order to avoid negative impacts to fish habitat. You may proceed with your right-of-way maintenance project without a DFO review when you meet the following conditions:

- the work involves the maintenance of vegetation in an **existing** active right-of-way for a transportation or utility corridor and not construction of a new right-of-way or reactivation of an old right-of-way,
- it is an existing right-of-way at the location where it intersects and crosses a water body, the right-of-way is perpendicular or near perpendicular to the water body,
- it does not include complete removal of vegetation adjacent to the water body,
- it involves the use of vegetative maintenance techniques that allow the root system to stay intact, to help bind the soil and encourage rapid colonization of low-growing plant species,
- the maintenance activities are not currently covered by an existing DFO approved management plan, an approved work practice or according to the conditions of a previous government review, and
- you incorporate the *Measures to Protect Fish and Fish Habitat when Maintaining Rights-of-way in Riparian Areas* listed below in this Operational Statement.

If you cannot meet all of the conditions listed above and cannot incorporate all of the measures listed below then your project may result in the violation of subsection 35(1) of the *Fisheries Act* and you could be subject to enforcement action. In this case, you should contact the DFO office in your area if you wish to obtain DFO's opinion on the possible options you should consider to avoid contravention of the *Fisheries Act*.

You are required to comply with all municipal, provincial, territorial and/or federal legislation that applies to the work being carried out in relation to this Operational Statement. In British Columbia, please contact the Water Stewardship Division, Ministry of Environment (**http://www.env.gov.bc.ca/wsd/water_rights/licence_application/section9/index.html**) for information the Provincial *Water Regulation* notification requirements when planning to conduct maintenance of riparian vegetation in existing rights-of-ways in or around BC waters.

The activities undertaken in this Operational Statement must also comply with the *Species at Risk Act* (**http://www.speciesatrisk.gc.ca**). For general information on aquatic SARA species visit the following web site: **http://www.dfo-mpo.gc.ca/species-especes/actMeans/actMeans_criticalHabit_factsheet_e.asp** and/or contact DFO by email at **SARA@pac.dfo-mpo.gc.ca**.

If you have questions regarding this Operational Statement, please refer to the list of **Frequently Asked Questions** (**http://www-heb.pac.dfo-mpo.gc.ca/decisionsupport/os/os-faq_e.htm**) or contact DFO Regional Headquarters at 1-866-845-6776.

Please notify DFO 10 working days before starting your work by filling out and sending the Pacific Region Operational Statement **notification form** directly to DFO Regional Headquarters. This information is requested in order to evaluate the effectiveness of the work carried out in relation to this Operational Statement. It is recommended that you keep a copy of the Operational

Statement at the work site to demonstrate to Habitat and Fishery Officer staff that the conditions and measures, as outlined in the OS, are being followed.

Area of Application
This Operational Statement applies to the province of British Columbia and Yukon Territory freshwater systems only.

Measures to Protect Fish and Fish Habitat when Maintaining Riparian Vegetation in Rights-of-way

1. While this Operational Statement does not cover the complete clearing of riparian vegetation, the alteration (e.g., topping and pruning) of select plants may be necessary to meet operational and safety needs.

2. Combined maintenance activities (e.g., mowing, brushing, topping, slashing, etc.) will affect no more than one third (1/3) of the total woody vegetation, such as trees and shrubs, in the right-of-way within 30 metres of the **high water mark** (**http://www-heb.pac.dfo-mpo.gc.ca/decisionsupport/os/definitions_e.htm**) in any given year.

3. When practicable, alter riparian vegetation in the right-of-way by hand. If machinery must be used, operate machinery on land (above the **HWM**) and in a manner that minimizes disturbance to the banks of the water body.

- **3.1.** Machinery is to arrive on site in a clean condition and is to be maintained free of fluid leaks, invasive species and noxious weeds.
- **3.2.** Wash, refuel and service and store fuel and other materials for the machinery, which include hand tools, at locations away from the water to prevent any deleterious substance from entering the water body.
- **3.3.** Keep an emergency spill kit on site in case of fluid leaks or spills from machinery.
- **3.4.** Restore banks to original condition if any disturbance occurs.

4. Machinery fording the watercourse to bring equipment required for maintenance to the opposite side is limited to a one-time event (over and back) and should occur only if an existing crossing at another location is not available or practical to use. A *Temporary Ford Stream Crossings* Operational Statement is also available.

- **4.1.** To exercise this option, the stream bed at the fording site must be comprised of stable gravel or bedrock and the stream banks must be low and stable.
- **4.2.** If minor rutting is likely to occur, stream bank and bed protection methods (e.g., swamp mats, pads) should be used provided they do not constrict flows or block fish passage.
- **4.3.** Grading of the stream banks for the approaches is not permitted.
- **4.4.** If the stream bed and banks are steep and highly erodible (e.g., dominated by organic materials and silts) and erosion and degradation are likely to occur as a result of equipment fording, then a temporary crossing structure or other practice should be used to protect these areas.
- **4.5.** The one-time fording should prevent disruption to sensitive fish life stages by adhering to appropriate fisheries **timing windows** (**http://www-heb.pac.dfo-mpo.gc.ca/decisionsupport/os/timing_e.htm**) .
- **4.6.** Fording should occur under low flow conditions and not when flows are elevated due to local rain events or seasonal flooding.

5. When altering a tree that is located on the bank of a water body, ensure that the root structure and stability are maintained.

6. Stabilize any waste materials removed from the work site to prevent them from entering the water body. This could include covering spoil piles with biodegradable mats or tarps. All long-term storage of waste materials should be kept outside of the riparian area.

7. Vegetate any disturbed areas by planting and seeding with native trees, shrubs or grasses and cover such areas with mulch to prevent erosion and to help seeds germinate. All seeding and/or planting trees should follow the DFO guidance on **Riparian Revegetation** (**http://www-heb.pac.dfo-mpo.gc.ca/decisionsupport/os/riparian-reveg_e.htm**). If there is insufficient time remaining in the growing season, the site should be stabilized (e.g., cover exposed areas with erosion control blankets to keep the soil in place and prevent erosion) and vegetated the following spring.

- **7.1.** Maintain effective sediment and erosion control measures until re-vegetation of disturbed areas is achieved.

Appendix C

Best Management Practices (BMPs) for Erosion Prevention and Sediment Control

1 BEST MANAGEMENT PRACTICES FOR EROSION PREVENTION AND SEDIMENT CONTROL

For successful erosion prevention and sediment control (EPSC), erosion prevention measures must be the primary control implemented on a construction site. Erosion prevention is proactive source control. By preventing the initial detachment and transport of sediment, erosion prevention minimizes the cost and effort associated with sediment control. Successful erosion prevention measures will reduce or eliminate the need for sediment control measures.

1.1 BEST MANAGEMENT PRACTICES FOR EROSION PREVENTION AND SEDIMENT CONTROL

While erosion prevention aims to prevent the initial detachment and entrainment of material, sediment control is a secondary, non-source control with the objective of collecting and retaining sediment some distance away from its source. Erosion prevention will always be the first objective, because the need for sediment control is reduced if minimal erosion is occurring. Although initial costs for sediment controls may be cheaper than initial costs for erosion controls, sediment controls may have higher long-term costs because they require ongoing maintenance and are less effective than erosion controls.

The key goal of sediment control is to decrease surface water flow velocities to prevent delivery of entrained material into waterways. Limiting the energy of runoff by slowing water movement reduces erosion and promotes deposition of entrained particles.

Given the environmental conditions in the Project area – high rainfall and runoff, erodible soils, and steep slopes – some degree of soil erosion is likely to occur even with comprehensive erosion management. Sediment control measures are required to capture eroded material before it is released to waterways. In order to limit disturbance associated with land clearing along the Brucejack Access Road, no large sediment ponds will be prescribed during construction. In general, sediment ponds are not feasible along linear infrastructure projects. However, smaller sediment retention pools or traps may be useful for localized, site-specific applications (e.g., culvert inlets).

The general erosion prevention measures are divided into three main categories:

- soil stabilization and protection;
- minimization of runoff velocity; and
- minimization of runoff volume.

1.1.1 Sediment Retention

Sediment control is ideally used only to manage the residual, minimal sediment production that occurs after effective erosion prevention controls have been implemented. Sediment control

structures slow runoff velocity by forcing runoff to pool. This allows materials to settle out of suspension. Sediment control is most effective at retaining larger particles (e.g., sand and coarse silt). Its effectiveness at retention decreases as the particle size decreases. Sediment controls are most effective at retaining sediment when runoff sediment concentrations, velocity, and volume are low. Therefore, sediment control effectiveness is lowest when the need for it is greatest (i.e., during periods of heavy precipitation).

Common measures for slowing runoff include sediment fences, berms, earth dikes, and sediment retention pools/traps. Some erosion prevention measures may provide minimal sediment control as a secondary function. These include slope roughening and terracing, wattles, fascines, check dams, and gabions. Additionally, maintaining vegetative buffer zones at the perimeter of construction sites and along streambanks is a highly effective and inexpensive method of preventing sedimentation. Vegetative buffers are particularly important when construction takes place near streams.

Regular inspection and maintenance of sediment control structures is essential, not only so they remain functional but also to remove the accumulated sediment that they trap and impound. Failure of a sediment control structure containing a large accumulation of impounded sediment can cause rapid delivery of significant quantities of sediment to streams, potentially creating a severe impact to water quality. Most sediment control structures (with the exception of large sediment retention basins, which are not feasible for access road construction) are only temporary measures to prevent sediment transport while construction is ongoing, or post-construction before the site is stabilized (i.e., prior to vegetation establishment).

1.1.2 Soil Stabilization and Protection

Exposed soils erode more quickly than soils that are covered or bound together by vegetation. Therefore, a fundamental goal of erosion prevention is to minimize the amount of time that bare soil is exposed to the elements.

1.1.2.1 Vegetation

Vegetation is the most cost-effective, long-term surface erosion prevention method. It helps to maintain the quality of the soil structure and protects the soil from rainsplash impact. Hence, natural vegetation will be left in place for as long as feasible during construction. Although it may be necessary to remove large standing vegetation such as shrubs and trees, ground cover plants will be retained, where feasible.

When construction activities are complete in an area, slopes with exposed soils will be re-vegetated as soon as feasible to prevent surface erosion. Most erosion occurs in the first year when soils are exposed, during and immediately following construction. Throughout the first few years following construction there will likely be significant re-vegetation work required as the cuts and fills stabilize. Re-vegetation will also be considered in ditchlines to ensure that permanent ditches remain stable. Spot seeding to fill in gaps in vegetation is an effective way to minimize the scope of potential problems.

Best management practices (BMPs) such as surface texturing, mulching, and application of topsoil can be used in conjunction with seeding to promote vegetation germination and growth and

enhance the effectiveness of re-vegetation efforts. Following construction, disturbed areas will be re-sloped to a stable configuration and seeded with an approved rapidly establishing, weed-free native seed mix by broadcast seeding or hydroseeding. The soils will be assessed for fertility prior to seeding and a fertilizer applied where required. Where feasible, native plants removed from the construction site will be salvaged for use at adjacent sites where construction is completed. Bioengineering with willows and plantings of other shrubs may be used where additional stabilization is required.

Mulching and application of topsoil are recommended in conjunction with re-vegetation efforts to add protection after seed and fertilizer have been applied, but prior to vegetation establishment. Organic matter provided by mulch and topsoil has high nutrient- and moisture-holding capacities and helps to protect seeds prior to germination and growth. Local and natural materials will be used whenever feasible. Straw, wood chips, and green mulch (produced by shredding slash and other vegetation) are effective mulches and may be highly cost-efficient if materials are locally abundant. Application of topsoil can also make use of local materials, as topsoil stripped from a construction site can be reapplied once construction is complete. Topsoil application is particularly useful in areas where the soil is nutrient deficient or shallow.

1.1.2.2 Temporary Covers

At sites that are temporarily inactive, or when the seasonal timing of construction is not conducive to re-seeding, slopes will be covered with brush material, rolled erosion control products (RECPs), or polyethylene sheeting, where required. The material protects the soil from rainsplash erosion and can be easily removed when activity resumes at the site.

1.1.2.3 Slope, Ditch, and Outlet Protection

Slopes, ditches, outlets, and other areas which receive concentrated flow are highly susceptible to erosion. Gabions, retaining walls, and riprap armouring can be used to protect these areas. Gabions and retaining walls are durable and effective for relatively high slopes. Construction of gabions and retaining walls is often expensive and labour intensive, but they provide long-lasting slope stabilization in extreme conditions.

Rock armouring or riprap can be used to line slopes or outlets, protecting against erosion by stabilizing soil and dissipating runoff energy. It is easily installed and effective in highly erodible soils, but it will be applied in conjunction with other erosion prevention measures, including an underlay of geotextile or gravel to prevent displacement of finer materials.

These protective measures will be used in conjunction with runoff control BMPs (discussed below), not as a stand-alone erosion prevention approach.

1.1.3 Minimization of Runoff Velocity

When flow velocities are decreased, the erosive power of water is reduced. Minimizing runoff velocity limits rill and channel erosion. Additionally, lower runoff velocity promotes the deposition of entrained material as close as feasible to its source, thereby reducing the amount of sediment that is transported into waterways.

1.1.3.1 Slope Length

Slope length is the distance along a slope where water may flow unimpeded. As slope length and steepness increase, runoff velocity increases. Slope length will be limited by installing slope breaks that can redirect or absorb surface water energy. Steeper slopes require shorter lengths to minimize runoff velocity. As a general rule, erosion hazard exists if slope length for a given gradient exceeds the maximum figures given in Table 1.1-1. Additionally, shorter slope lengths may be required in order to enhance the functionality of specific EPSC measures (e.g., maximum allowable slope lengths contributing runoff to sediment fences, listed in Appendix E SEPSCP). Common slope breaks include sediment fences, rock or brush berms, wattles, fascines, and drainage ditches. It is important that slope breaks are installed properly and maintained so that they do not cause erosion by concentrating and channelizing flow.

Table 1.1-1. Maximum Slope Length as a Function of Slope Gradient

Slope Gradient (%)	Maximum Slope Length (m)
0 - 7	100
7 - 15	50
> 15	25

Source: GVSDD (1999) and ID DEQ (2005).

Flow velocity reduction in ditches is particularly important, because channelized flow can quickly pick up speed and energy to become a major erosive force. Check dams reduce gradient in ditches, thereby slowing the velocity of concentrated flow and triggering the deposition of the transported sediment. Check dams are relatively simple and inexpensive to construct, and can generally be made from locally available material such as rocks or brush. At the outlets of ditches or other areas with channelized flow (such as slope drains or culverts), energy dissipators are useful to slow flow velocity and dissipate flow energy.

Culvert installation can limit slope length and runoff velocity if culverts are extended along steep downslope areas. Water that would otherwise flow across the slope face can therefore be routed through the culvert and discharged where the gradient has lessened. Corrugated metal pipes may be more effective in slowing water velocity than culvert pipes with smooth interior walls.

On road surfaces, water bars and rolling dips can be used to minimize slope length and slow runoff velocity. Although these structures are easy to install and maintain, they require proper installation and regular maintenance to remain functional. As with slope breaks, improperly constructed and maintained water bars and rolling dips have the potential to cause erosion by concentrating flow or directing runoff onto unstable fill slopes.

1.1.3.2 Slope Configuration

Roughening or terracing through the construction of furrows or steps along a contour produces unevenness on exposed slopes. This decreases erosion potential by reducing flow velocities, trapping sediment, and increasing infiltration. Roughening the soil also promotes vegetation establishment following seeding.

1.1.3.3 Construction Sequencing

When clearing a site, working from the top of the slope to the bottom maintains the largest buffer zone between the disturbed areas and the receiving environment below. Hillslope runoff from the construction site will pass through the vegetated zone before entering the receiving environment, resulting in a decrease in overland flow velocity and an increase in sediment deposition.

1.1.4 Minimization of Runoff Volume

The key aims of erosion prevention measures in this category are to prevent upslope runoff entering a site, to decrease the likelihood of runoff being generated on the site and to minimize the volume of sediment-laden water requiring treatment in a sedimentation pond or other sediment control structure.

1.1.4.1 Soil Drainage

Soil drainage will be implemented prior to the commencement of construction activities. Draining the soil opens up pore space, thereby enhancing infiltration capacity and minimizing the generation of overland flow. Improved soil structure in well-drained soils helps to minimize erosion caused by heavy machinery during construction activities. Drainage can be achieved through the construction of temporary or permanent ditches. Where feasible, ditches will be installed in advance of construction on the rest of the site. Ditch configuration and spacing are dependent upon local drainage conditions and site access.

Pipe slope drains are often used in conjunction with ditches that direct runoff along the top of cut and fill slopes. Slope drains can provide effective temporary or permanent erosion prevention, but will always be used in conjunction with other erosion prevention measures such as armouring of the outlet.

1.1.4.2 Runoff Diversion

Diverting runoff from upslope of the construction site minimizes the amount of water flowing through the construction site. This limits the potential for generation of overland flow and for concentration of flow paths. Decreasing flow through the site also reduces the amount of eroded material that is generated from the site, therefore reducing the need for sediment control structures such as retention pools or traps.

A series of diversion ditches may be constructed on the upslope end of a construction site to capture and divert runoff. Diversion ditches are most effective when paired with other erosion prevention measures, such as rock armour and pipe slope drains.

1.1.4.3 Inclement Weather

To minimize the impact of large rain events, which can generate large amounts of runoff and subsequent erosion, major ground breaking activities and land clearing will be avoided during periods of high and sustained rainfall. A list of adverse weather shutdown triggers has been developed for construction activities.

Appendix D

Recommended Best Management Practices (BMPs) for the Brucejack Gold Mine Project

Erosion Prevention/ Sediment Control	Applications					Comments	
	Slopes	Ditches and Channels	Flat Areas	Borrow and Stockpile Areas	Road Surfaces	Advantages	Limitations
E/S	x	x	x	x	x	• Proactive and cost-effective • Identifies major construction and land disturbing activities and prescribes effective erosion prevention and sediment control practices prior to the start of construction • Focus on effective, cost-efficient erosion prevention controls rather than higher cost, less effective sediment controls	• Presumptive and subject to uncertainty • Only effective if construction procedures and control practices are regularly assessed and m conditions
E/S	x		x	x		• Roughens slope surface to reduce erosion potential and sediment production • Suitable for most soil types except very loose soils • Reduces runoff velocity and increases infiltration rates • May trap sediment laden runoff • Promotes vegetation development • Can be applied on slopes with a maximum gradient of 2H:1V • Inexpensive and easy to apply, can be implemented using commonly available heavy construction equipment • Provides temporary erosion prevention and sediment control (EPSC) benefits on sites that are not immediately topsoiled, mulched, or re-vegetated	• Unsuitable for loose soils • Not practical for steep slopes (limits dozer op • Provides limited sediment and erosion contro control measure • Limited application on slopes steeper than 2H • Most effective when combined with other EPS • Must be re-established after heavy rains
E/S	x			x		• Reduce erosion damage by capturing surface runoff and directing it to a stable outlet at a speed that minimizes erosion • Effective for slopes up to 50% • Can be implemented using commonly available heavy construction equipment	• Unsuitable for excessively steep slopes (> 50% • May cause sloughing if water infiltrates soil • Will need to be designed by qualified professi • Stable runoff outlets (e.g., vegetated areas) mu
E	x		x	x		• Organic mulches (e.g., compost, straw, wood chips) are a useful temporary measure to protect slopes for short periods and can be applied in conjunction with seeding • Inorganic mulches (e.g., gravel or rock blankets) can provide permanent erosion prevention • Inexpensive and easy to apply • Prevents soil particle detachment, decreases runoff velocity, promotes infiltration into soil, and prevents surface crusting and soil compaction • Promotes plant germination and growth	• Application on steep slopes may be difficult • Inorganic mulches may prevent the establishn • May deplete available nitrogen • Organic mulches have a limited functional life • Certain mulches (e.g., straw) can be easily blo runoff • Certain mulches may not be available or may • Most effective when combined with other EPS texturing/roughening)
E	x		x	x		• Provides suitable growth medium for vegetation on slopes 2H:1V and flatter • Useful in areas where soil is nutrient deficient or too shallow to provide adequate rooting depth for the growth of the desired vegetation • Topsoil stripped from a construction site can be reapplied • Optimizes performance of seeding and re-vegetation methods	• Limited to slopes 2H:1V and flatter • Applicability and cost-effectiveness are subjec available equipment; importing topsoil can in • Application is seasonally limited; topsoil will frozen or extremely wet • Will not be used as a stand-alone method, effe combined with associated erosion prevention

Erosion Prevention/ Sediment Control	Applications					Comments	
	Slopes	Ditches and Channels	Flat Areas	Borrow and Stockpile Areas	Road Surfaces	Advantages	Limitations
E	x	x	x	x		• Temporary seeding can be used on disturbed soils that require interim erosion prevention controls • Permanent seeding can be used to provide effective post-construction erosion prevention on disturbed bare soil that has been graded to final contour • Inexpensive • Effectiveness increases with time as vegetation develops • Increases the erosion prevention performance of other methods (e.g., organic mulches, straw wattles) by decreasing runoff volume and velocity	• May require periodic maintenance (e.g., fertili • Seeding may be difficult on steep slopes (mos • Seasonal limitations on seeding effectiveness • Freshly seeded areas are susceptible to erosion requiring temporary erosion prevention meas • Will be combined with other methods (e.g., sl topsoiling, mulching) to optimize performanc
E	x	x	x	x		• Effective for establishing a vegetation cover, especially where seedbed preparation is impractical • Can be used on an irregular soil surface • Large rocks, stones, roots and other large materials do not need to be removed from site • Can be used on steep or inaccessible slopes where other seeding and mulching methods may be impractical or unsafe • Hydromulching is relatively low cost compared to other mulching methods or rolled erosion control products (RECPs)	• Requires specialized equipment to mix and ap • Not practical where equipment cannot access • Areas where application has not been success applications • Not a fail-safe method; must be combined wit performance
E/S	x	x	x	x		• Establishes vegetative cover and root mat • Reduces flow velocities on vegetative surface • May trap sediment laden runoff • Grows stronger with time as root structure develops	• May be labour intensive to install • Re-vegetated areas are subject to erosion until • Watering may be required until plants are esta
E	x	x	x	x		• Provide immediate, effective temporary erosion prevention to bare soil or topsoiled surfaces where need for erosion protection is high • Provide immediate, effective temporary or permanent erosion prevention in a constructed ditch • Can be more uniform and longer lasting than mulch • Wide range of commercially available products allows for use across a range of slope and soil conditions • Prevents soil particle detachment, decreases runoff velocity, promotes infiltration into soil, and prevents surface crusting and soil compaction • Promotes plant germination and growth • Hand installation, does not require specialized equipment • Suitable for remote sites	• Installation may be labour intensive, proper si RECP onto soil correctly • Temporary RECP blankets require removal pr activities • Unsuitable for rocky slopes • Performance is dependent upon successful ve • Limited functional life (6 months to 3 years) • Cannot be installed on frozen ground, may be accumulation • Must not be used as a stand-alone erosion pre • Prone to failure if subjected to concentrated ru

Erosion evention/ ediment Control	Applications					Comments	
	Slopes	Ditches and Channels	Flat Areas	Borrow and Stockpile Areas	Road Surfaces	Advantages	Limitations
E	x	x	x	x		• Can provide highly effective temporary erosion prevention • Provides immediate effective prevention of erosion during rain events, short periods of inactivity or emergency spill response • Inexpensive, readily available in varying widths	• Must be installed by hand • Requires frequent inspection and maintenanc • Other mulch materials may be just as effective • Not effective as a long-term erosion preventio • Susceptible to displacement by water or wind • Concentrates runoff, increasing erosion poten receiving water source • Sediment-laden runoff must be directed into s as a sediment retention pond
E	x			x	x	• Can provide temporary or permanent post-construction runoff control • Can be used to collect and divert sheet flow or runoff at the top of a slope to reduce downslope erosion potential • Temporary ditches can be easily incorporated with permanent project drainage systems • Relatively easy to design and construct • Inexpensive, can be implemented using commonly available heavy construction equipment	• Must be sized for expected flows; professiona will convey large volumes of water or high ve • Riprap spillway and/or permeable outlet may • Channel lining (e.g., riprap) may be required • Sediment-laden runoff must be directed into s as a sediment retention pond • Regular inspection and maintenance required in ditches • Most effective when combined with other EPS
E	x		x	x		• Can be easily decommissioned or relocated as construction progresses • Relatively easy to design and construct • Inexpensive, can be implemented using readily available heavy construction equipment • Can be used to help keep work sites dry by intercepting overland flow upslope of an active work area • Can be used at crest of cut and fill slopes to intercept and prevent runoff over slope • Increases the erosion prevention performance of other best management practices (BMPs; e.g., RECPs on slopes, straw wattles, mulch) • Can be constructed easily and quickly using commonly available construction equipment • Can be used in conjunction with berms	• Geotechnical design required for fill heights i • May not be suitable for all soil types or sites • Limited to small catchment areas ≤ 2 ha • Riprap spillway and/or permeable outlet may • Channel lining (e.g., riprap) may be required • Sediment-laden runoff must be directed into s as a sediment retention pond • Regular inspection and maintenance required in ditches • Must not be used as a stand-alone erosion pre

Erosion Prevention/ Sediment Control	Applications					Comments	
	Slopes	Ditches and Channels	Flat Areas	Borrow and Stockpile Areas	Road Surfaces	Advantages	Limitations
E/S	x	x				• Slow runoff velocity by reducing gradient in ditches, decreasing the potential for erosion • Provide limited sediment capture and storage as a secondary benefit • Cheaper than gabion or armouring entire channel • Easily constructed using materials and equipment found on most construction sites	• Require extensive maintenance after high flow • Susceptible to failure if water undermines or c • Only provides partial sediment control; sand a detention time is too short to allow fine sedim • Limited functional life (6 months to 1 year) • May require design by qualified professional f velocities • Not to be used as a stand-alone erosion preve • Must not be used in natural watercourses • Rock check dams are more stable and effectiv
E	x	x				• Riprap used as slope lining protects against erosion by dissipating runoff energy • Riprap used as outlet lining protects against erosion by reducing the speed of concentrated flows and minimizing scouring • Durable, long lasting, flexible and low maintenance • Effective in ditches with higher flow velocities (2 to 5 m/s) • Effective for slopes up to 40% • Suitable for ditches or outlets in easily eroded soils • Easily constructed using heavy equipment • More effective than check dam structures in preventing erosion	• May be expensive compared to check dams; c available rock and rock transport and handlin • Rock must meet specification for gradation (si angularity • Must be combined with a non-woven geotexti prevent entrainment and displacement of fine underlying soil layer • Will need to be designed and specified by a qu • Must not be used as a stand-alone erosion pre • Must not be used in natural watercourses
E	x					• Often used in conjunction with diversion berms/ditches that collect and direct runoff along the top of cut and fill slopes • Effective erosion prevention measure prior to slope stabilization or before permanent drainage structures are ready for use • Can provide effective temporary or permanent erosion prevention, depending on circumstances and conduit material used • Relatively inexpensive, can be constructed using readily available materials • Depending on construction materials, may be easily disassembled and relocated as construction progresses	• Must be sized appropriately to accommodate • Erosion can occur at inlet/outlet if protection armouring) is not incorporated into design • Failure can result in severe gully erosion • Unsuitable for drainage areas > 4 ha • Sediment-laden runoff must be directed into s as a sediment retention pond • Must not be used as a stand-alone erosion pre

Erosion Prevention/ Sediment Control	Applications					Comments	
	Slopes	Ditches and Channels	Flat Areas	Borrow and Stockpile Areas	Road Surfaces	Advantages	Limitations
E	x	x				• Slows runoff velocity and dissipates flow energy in relatively short distances • Use at outlets of slope drains, culverts, conduits or channels with significant flow • Can be constructed using heavy equipment found on most construction sites • Usually constructed from angular rock, which may be readily available	• Small diameter rocks/stones can be easily dis • Grouted riprap armouring may break up due heaves, or settlement • May be expensive if riprap materials or concr • May require design by qualified professional velocities • Rock must meet specification for gradation (si angularity • After flowing over dissipator, runoff must be area or into a non-erodible ditch • Severe erosion may occur if a portion of the di • Must not be used as a stand-alone erosion pre
E	x	x			x	• Rectangular wire-mesh cages that are filled with rock and wired together, forming a protective but permeable structure for slope stabilization • Durable, long lasting, and low maintenance • Effective for slopes up to 40% • May be less expensive than riprap • Suitable for resisting high flow velocity	• Construction and installation may be labour i • Extra costs associated with gabion basket mat • Wire used for baskets may wear off quickly in loads
E	x				x	• Provide long-term slope protection or stabilization under extreme conditions • Effective for slopes up to 67%	• May be damaged by freeze-thaw cycles • Require design by qualified professional • Relatively expensive and labour intensive to i
E/S	x					• Inexpensive, easy to install by hand • Function well in freeze-thaw conditions • Can be used on slopes too steep for silt fences or straw bale barriers (up to 1H:1V) • Provide grade breaks and reduce erosion by decreasing runoff velocity • May trap sediment laden runoff • Can be combined with live staking as a bioengineering control	• Installation is labour intensive • Not appropriate for EPSC in concentrated flo • Short functional life (1 to 2 years) • Most effective when combined with other EPS to provide long term erosion prevention)
E		x			x	• Minimize the volume and velocity of road surface runoff • Minimize slope length and potential for erosion • Can be constructed easily and quickly using commonly available construction equipment • Easy to maintain	• Require maintenance to remain functional; eff fill with sediment and vehicle traffic degrades • Will cause erosion if runoff is directed onto u • Can direct sediment into watercourses if locat • Most effective when combined with other EPS

Erosion Prevention/ Sediment Control	Applications					Comments	
	Slopes	Ditches and Channels	Flat Areas	Borrow and Stockpile Areas	Road Surfaces	Advantages	Limitations
S	x	x	x	x		• Force low volume overland flow to pool so that suspended sediment can drop out of suspension • Inexpensive • Trap sediment laden runoff • Easy to install, easily replaced if damaged • Readily available	• Must not be installed in or across defined drai • May fail in high runoff events; not for use at lo expected to occur • Limited to locations where adequate space is a • Susceptible to damage, short functional life (a • Inappropriate sediment control for fine textur • Installation can be difficult in compacted or ro dense ground-covering vegetation • Retained sediment must be removed and fenc maintained on a regular basis • Combine with erosion prevention measures to
S	x	x	x	x	x	• Force low volume overland flow to pool so that suspended sediment can drop out of suspension • Easily replaced if damaged • Can be constructed from fill materials that may be readily available on the work site • Provide perimeter sediment control around active construction site or stockpile • Can be used in conjunction with, or instead of, diversion ditches	• Must not be installed in or across defined drai • May fail in high runoff events; not for use at lo expected to occur • Improper installation will concentrate runoff a erosion under or around ends of berm • Retained sediment must be removed and berm maintained on a regular basis • Combine with erosion prevention measures to
S	x		x	x		• Force low volume overland flow to pool so that suspended sediment can drop out of suspension • May provide effective sediment control for coarse soils • Easily replaced if damaged • Can be constructed from fill materials that may be on a work site or readily available to the work site • Provides perimeter sediment control around active construction site or stockpile	• Must not be installed in or across defined drai • May fail in high runoff events; not for use at lo expected to occur • Improper installation will concentrate runoff a erosion under or around ends of dike • Retained sediment must be removed and dike on a regular basis • Combine with erosion prevention measures to
S	x	x	x	x	x	• Collect and store sediment that is generated from active construction sites or sites that have not yet been stabilized by vegetation • Can be used at cross-drain culvert inlets to reduce sediment loads in road surface runoff • Can be easily installed along linear infrastructure and do not require design by a qualified professional, unlike larger sediment ponds	• May only partially retain suspended sediment pass directly through most pools/traps • Efficiency decreases as pools fill with sedimen accumulated sediment • May require specialized materials or structure structures for outlets) • Only suitable for relatively small contributing • Combine with erosion prevention measures to
			x	x	x	• Controls erosion at the source and prevents sediment transport	• May need to be applied multiple times per da humidity and the amount of traffic on the surf • Some dust suppressants may be deleterious su courses • Requires specialized equipment to apply to th

Weekly Monitoring Report Form

Weekly Environmental Monitoring Summary Report

Date:	**Week:**
To:	**From:**
Cc: see distribution list at end	**Weekly Report #:**
Project Component: (e.g. Brucejack Access Road, Brucejack Mine Site, etc.)	**Specific Location:** (e.g. km XX to XX; diversion ditch A)

A) SUMMARY OF CONSTRUCTION ACTIVITIES

Provide overview of the nature and scope of construction activities, weather, and other factors that provide the reader with a quick grasp of the Project component being monitored, environmental performance, and any issues encountered during the past week. Divide out by Project component and further divide by location along Project component if necessary.

Meetings

Summarize meeting issues and outcomes including environmental orientation training, environmental plans (EPP, CEMP) content and intent, archaeological features and monitoring, pre-clearing survey findings, work windows, reporting requirements, buffers, and permits.

B) SUMMARY OF ENVIRONMENTAL MONITORING ACTIVITIES

Communication

Summarize any pertinent communication between Environmental Monitors, Contractor, Pretivm, or regulatory agencies.

Environmental Orientation Training

Summarize any training delivered and orientations including participants.

On-site Environmental Inspections and Findings

Describe any inspections, locations, on-site presence of Environmental Monitors, key findings, and overall scope of activity for the week. Provide photos and descriptions of challenging or successful activities. Ensure reader quickly obtains understanding of the scope, complexity of monitoring relative to the scale of activity, and nature of the environmental issues at the site. Comment on follow-up from previous issues and close out any issues. Note data collection activities for the week and locations, if in addition to the established ongoing monitoring program.

Erosion Prevention and Sediment Control

Water Quality

Spill Prevention and Emergency Response

Wildlife Interaction Summary

Waste Management

Air Quality and Noise Management

Heritage Resource Protection

C) INCIDENT SUMMARY

Summarize the nature, issue, contractor performance/actions, and outcomes of any environmental incidents. Describe impacts, remediation, and follow-up measures and notification to agencies/parties.

Prepare a tracking table which assigns a unique number to each event for week-to-week follow-up until closure.

D) EMERGENCY/UPCOMING ISSUES

Provide advance awareness and comments on upcoming issues for the following week.

E) ATTACHMENTS

1 Introduction

The Brucejack Project is a high-grade gold mine located 65 km north of Stewart in northwestern British Columbia, Canada. The project is 100% owned by Pretium Resources Inc. (Pretivm). The mining method selected for Brucejack is Long Hole Open Stoping (LHOS) with cemented paste backfill, currently mined at a rate of 3,800 tonnes of ore per day (tpd).

Pre-production development commenced in the third quarter of 2015 with commercial production commencing in the third quarter of 2017. In late 2017, Pretivm applied to increase the production rate to 3,800 tpd.

The following describes the ventilation plan to support the 3,800 tpd production rate. This scenario represents the peak ventilation demand for the mine.

To ensure adequate ventilation for production operations, airflow requirements were estimated and simulations were run using Ventsim Visual 4.

2 Ventilation requirements

The total ventilation requirements for the 3,800 tpd production rate and drive are based on the airflow required for the diesel powered mobile equipment fleet, underground fixed facilities and a leakage and balancing factor. The airflow requirements for underground fixed facilities are unchanged as no new facilities are planned.

2.1 Mobile equipment

The airflow required for the mobile diesel equipment follows the ventilation requirements of the Health, Safety and Reclamation Code for Mines in British Columbia, Section 4.6.1 (3). Therefore a minimum of 0.06 $m^3/s/kW$ of operating diesel engine power is used.

Required ventilation quantities are estimated based on the current diesel equipment fleet as well as the additional equipment planned to support the increased production and exploration drive development.

The mining contractor is supplying the bulk of the underground mobile equipment. Every engine operating underground is CANMET certified.

Utilization factors are applied to each piece of equipment, given in Table 2-1.

Table 2-1 below shows the mobile equipment fleet with engine power, utilizations and the required ventilation volume. Note the fleet sizes and utilizations shown represent the maximum anticipated to meet full production.

Table 2-1 Mobile equipment ventilation requirements 2022

						376.3
						413.9

As shown in Table 2-1, the total estimated airflow required for the mobile equipment fleet is 376.3 m^3/s.

2.2 Fixed facilities

The Brucejack mine design includes the following underground fixed facilities:

- Crusher
- Magazine
- Conveyor sacrificial belt level

All fixed facility locations are near a major mine intake route. Some intake air is diverted through these areas to provide ventilation. This airflow will report directly to Vent Exhaust Raise 2 (VR-2) (refer to Figure 3-1). This arrangement prevents air pollutants and dust produced in this area from being introduced into the mine primary circuit.

The airflow allowance for each area is described in greater detail below.

2.2.1 Crusher tipple and truck loop

Primary airflow must be provided through the crusher tipple level and within the truck loop to transport dust and dilute diesel emissions from trucks dumping at the tipple and travelling within the truck loop.

The largest diesel powered piece of equipment entering the tipple area is a 30-tonne, 305 kW truck. To satisfy the DEE dilution requirements for the truck, 18 m^3/s is required in each of the two legs of the truck loop. This airflow will also remove the dust generated in the tipple area and is exhausted down to the sacrificial belt conveyor level via a raise and exhaust fan. The raise is located on the opposite side of the rock-breaker cab to pull dusty air away from the operator and report to the VR-2 exhaust raise. A dust suppression system in the form of water sprays at the grizzly area is included.

2.2.2 Magazine

The magazine is a loop located off the east leg of the truck loop. Fresh air for this area is drawn from the 1335 level of the main VOK ramp. The airflow pattern through the magazine is intended to provide a single pass flow of air through the magazine and exhaust down the crusher exhaust raise to VR-2. The airflow through the magazine is approximately 7.5 m^3/s, sufficient to maintain a minimum velocity of 0.3 m/s.

Fire doors at the entry and exit points are included. In the event of a fire in the magazine loop, the doors would automatically close and contain the smoke within. A man-door is adjacent to each fire door.

2.2.3 Fuel bay and underground workshop

There is a fuel bay loop developed located at the north end of the truck loop. The fuel bay is currently inactive with no refueling infrastructure installed. The development for an underground shop is currently incomplete and no servicing facilities are in place.

If the fuel the bay and workshop are completed in the future, an appropriate airflow allowance will be provided.

2.2.4 Sacrificial belt level

The sacrificial conveyor between the lower main conveyor and the crusher is ventilated with air from the lower main conveyor decline. Approximately 12.5 m^3/s is drawn from the lower main conveyor decline and exhausted through a roll-up door regulating the air to VR-2.

The sacrificial conveyor regulator is part of the recommended smoke management strategy in the event of a fire along the conveyor ramp. In the event of conveyor fire, the door will be automatically fully opened for all ventilation air from the main conveyor declines to be diverted to the exhaust VR-2.

The total airflow allowance for the currently active fixed facilities is approximately 55 m^3/s.

2.3 Leakage and balancing

All mines experience leakage and balancing inefficiencies. The magnitude of these inefficiencies is dependent on a number of factors and typically ranges from 10% to 50% of total mine air flows. Being a new mine, leakage can be towards to the lower end of this range and has allowed a 10% addition to the total airflow requirements of this mine.

Regular monitoring and maintenance of all ventilation controls will be undertaken to reduce leakage.

2.4 Total airflow requirement

The total airflow requirement for the Brucejack mine during 3,800 tpd production is as follows:

- Diesel equipment - 338.6 m^3/s
- Fixed facilities – 55 m^3/s
- Leakage and balancing (10%) - 39 m^3/s
- **Total – 413.9 m^3/s**

3 Ventilation circuit

The Brucejack ventilation system is designed as a push system - the primary fans are located on surface, at the conveyor ramp and the West Zone portals.

Intake connections to the surface will consist of the West Zone ramp and the conveyor ramp. These two intake airways provide sufficient ventilation capacity to support steady state mining operations. To ensure the temperature of the air does not enter the mine below the freezing point, mine air heaters are fitted in front of the primary fans.

The VOK production ramp is connected to the intake ramps to deliver fresh air to the active production levels. An escape-way ladder system is installed in fresh air raises in parallel with the production ramp.

Fresh air travels from the production ramp, along the footwall drives and exhausted to return air raises located at the extremities of the level. Regulators are installed at the raise connections to distribute the required volume of air to the level. An appropriately designed auxiliary fan and duct system force fresh air from the footwall drives to active stope faces.

The underground fixed facilities have a dedicated return air raise (VR-2) to eliminate the introduction of dust and other unwanted contaminants into the production areas. The volume of air flowing through the crusher and workshop areas is controlled with a combination of fan and regulators.

Figure 3-1 shows an isometric view of the Brucejack ventilation system with airflows and velocities in key airways. This ventilation configuration represents the stage of the mine life chosen for primary fan selection.

Figure 3-1 Brucejack ventilation system - looking east

Figure 3-2 shows an isometric view of the ventilation arrangement for the fixed facilities area. The arrows show the airflow direction of travel.

Figure 3-2 Fixed facilities ventilation arrangement

Figure 3-3 shows a plan view of a typical production level.

Figure 3-3 Typical production level

4 Primary fans

Ventilation modelling was undertaken for the purposes of appropriate primary fan selection during the feasibility study phase. Over the life of mine there are a large number of settings for the ventilation circuit, depending on the type of activities and their location throughout the mine. The modelled scenario attempts to reflect the peak primary fan duties that could be reasonably expected. This scenario involves development occurring in conjunction with full production in the upper, middle and lower mining blocks of the VOK (as shown in Figure 3-1 above).

The primary fan duties is as shown in Table 4-1.

Table 4-1 Primary fan duty

Description	Specification
Duty	Two each @ 229 m^3/s @ 1,625 Pa
Fan Diameter	2.4 m
Type	Horizontal mount axial mine fan
Configuration	Two forcing fans, each connected with ducting to the WZ access decline and the VOK conveyor decline

Description	Specification
Voltage	575 V
Fan Motor	600 kW at 1180 rpm, variable frequency drive capability

The fans are controlled from surface and include a complete package of airflow, pressure and vibration monitoring capability. The fans and motors are also capable of reversal, providing ~ 60% of the forward flow.

5 Mine air heating

A mine air heating system is included for the Brucejack operation. The target intake air temperature will approximately 2°C. At the Brucejack mine, the primary purposes of this is to:

- minimize the potential that ice can accumulate on the roadbed of either the main decline or the conveyor decline,
- protect water pipes and other infrastructure in those main intakes, and to protect these drifts from freeze/thaw cycles.

Additionally, heating the intake air can offer a modest increase to the comfort of the mine workers, who may be exposed outside of equipment cabs.

During the 3,800 tpd production phase, 413.9 m^3/s of air will require heating when the surface temperature is near freezing. Mine air heating is provided for with a hybrid heating system. Primary heating is electrical resistance heaters with a direct fired propane system to provide heating at peak times when the electric system capacity is exceeded. The mine air heating system is installed at both intake portals.

The specifications of the heating system is shown below in Table 5-1.

Table 5-1 Heating system key specifications

Overall heater data	
Airflow through each heater	229 m^3/s
Total heat load (each heater)	7 MW (electric and propane heater)
Winter Design Entering Dry Bulb Temp.	-34°C
Winter Design Leaving Dry Bulb Temp.	+2°C
Electric heater data	
Heating capacity/heater	2 MW
Coil type/Material	80% nickel, 20% chromium, Grade A resistance wire
Power supply (V/Ph/Hz)	600/3/60
Propane heater data	
Heating capacity / heater	5 MW

Burner material	Aluminum casting and stainless Wings
Fuel flow required (Per Burner / Total)	97 Nm3/hr / 193 Nm3/hr
Burner Control	4-20 mA fully modulating

A carbon monoxide detection system is included for both heaters. The detector will shut down all the heater units in the event of CO concentrations exceeding 25 ppm. As per Health, Safety and Reclamation Code for Mines in British Columbia regulation 4.4.19 (3), the sensor are installed approximately 15 m downstream of the heated air manifold to allow sufficient air mixing.

6 Emergency preparedness

6.1 Refuge chambers

A permanent refuge station designed for emergency refuge of 40 persons is located near the truck loop on 1,335 level. It acts as lunch room during non-emergencies. The refuge chamber is provided by MineARC and the major components of the system include:

- Secondary oxygen supply – medical grade oxygen cache, sized to provide O_2 at a minimum rate of 0.5L per occupant, per minute, for duration of refuge.
- Third source of breathable air – sodium chlorate O_2 candle.
- Carbon dioxide removal – CO_2 removal system capable of removing no less than 24 L CO_2 per person, per hour, for the duration of the refuge, in order to maintain levels at less than 1%.
- Carbon monoxide removal – CO removal system capable of maintaining levels below the maximum exposure limit of 25 ppm.
- Cooling & dehumidifying – a cooling system with a nominal capacity of 130 watts per person, to mitigate heat loads of occupants and additional heat sources, with the ability to dehumidify the chamber interior.
- Atmospheric monitoring – ability to monitor levels of oxygen, carbon dioxide and carbon monoxide within the chamber and outside the chamber during emergency.
- Emergency food and water rations
- UPS battery backup
- Inverter charging system
- Vent Doors / Airlock
- Compressed air management

Compressed air sourced from surface compressors provide compressed air to the chamber. If the compressed air line is compromised during an emergency, the refuge chamber is capable of supporting up to 40 people for up to 72 hours.

Portable MineARC refuge chambers are also installed for personnel working in outlying areas of the mine where secondary means of escape has not been established. They are relocated relative to the active working areas to be within the average walking pace duration of a personal self-rescuer device, within approximately 750 m. Brucejack has for four, 16-person and one 12-person MineARC refuge chambers underground. These portable chambers in combination with the permanent chamber are sufficient for the maximum number of anticipated personnel working underground each shift.

The portable chambers contain the same features and performance of the permanent chamber. A compressed air line from surface compressors is reticulated to each portable refuge chamber.

6.2 Fire modelling

Extensive fire modelling of numerous fire scenarios was undertaken as part of the emergency preparedness for the Brucejack mine. The fire modelling was completed by external consultants, AMEC Foster Wheeler – the report can be found in Appendix B.

Five cases were simulated that represent six scenarios including: VOK conveyor decline fire, WZ access decline fire, WZ ramp fire, VOK ramp fire, and a production level fire. Stench gas distribution was also modelled. As an outcome of these models, countermeasures and evacuation routes were recommended and subsequently adopted as part of the emergency planning.

6.3 Conveyor decline

Brucejack mine uses the conveyor ramp as a main ventilation intake to the VOK mine workings. Under normal conditions, the ventilation intake air flows down both the upper and lower conveyor legs. When the airflow passes the sacrificial transfer conveyor, a small portion is drawn off to ventilate the transfer conveyor at the bottom of the crusher chamber. The remaining air flows into the main production ramp at about the 1290 m level.

This arrangement places a risk to the VOK district below the 1335 m level in the event of a fire along the conveyor decline. Mine fire modelling was completed by external consultants (AMEC Foster Wheeler). Part of this study included establishing the best strategy to implement in the unlikely event of conveyor belt fire.

Based on these simulations, the response to a conveyor fire is:

- Close the fire doors in the conveyor access ramps

- Fully open the regulator that exhausts the sacrificial conveyor area to VR2.
- The VOK conveyor portal fan is slowed down to 50% of its steady state speed.

The fire detection system installed at Brucejack is capable of automatically performing the closure of the appropriate fire doors.

This procedure is shown in Figure 6-1. The colored drifts shown the areas affected by fire contaminants.

Figure 6-1 Conveyor fire procedure

This approach does not materially impact the flow of air that would be perceived by the underground workers, which should help avoid confusion during the evacuation process.

To reduce the risk of a conveyor fire, the conveyor belting is fire retardant. The Brucejack mine includes an extensive fire detection system for the conveyance system including the crusher and transfer stations and the VOK portal building. In the unlikely event of a conveyor fire, the system will automatically implement the closure of the required fire doors.

The entire conveyor system is also provided with firefighting equipment in the form of high flow/extended discharge Red Line type fire extinguishers. To maximize the efficacy of these extinguishers a high sensitivity smoke detection in the VOK Portal (downstream of the main fan), transfer station, and crusher station is included.

In addition, standpipe systems are installed at the crusher station, transfer Station and VOK portal building where pulleys create a greater source of friction and potential ignition.

Further details of these systems can be found in Appendix A.

6.4 Stench

A stench gas system is installed at the primary fresh air intakes at the West Zone and conveyor ramp portals. In the event of a mine-wide emergency requiring evacuation, if the mine's ventilation system remains functioning and intact, a stench warning system is capable of alerting the workforce of the necessity to evacuate or travel to the nearest place of refuge.

Stench gas modelling was undertaken as part of the fire modelling work completed by the external consultants. Modelling indicates that after releasing stench at both portals, stench is distributed to the fixed facilities, crusher, and a portion of the VOK production ramp. After ten minutes, all of the likely active areas of the mine have been alerted; however, areas that are not under active production or development activities will not be reached by this time.

Radio communication is an additional key component of the emergency alert protocol.

6.5 Underground fire detection and protection

The Brucejack mine includes an extensive fire detection and protection system. The system includes high sensitivity smoke detection, fire alarms and fire suppression at the following facilities.

- VOK portal building

- Conveyor ramps and transfer station
- Permanent refuge station
- Crusher
- Substation
- Paste plant booster station

High sensitivity smoke detection (Vesada) systems are located in key areas to initiate fire alarms and automatically close the required fire doors. The fire alarms will initiate the manual control of the conveyor systems and primary fans. The detailed design of these systems is provided by Tyco Integrated Fire and Security and can be found in Appendix A.

6.6 Mobile equipment fire protection

All mobile equipment operating underground will carry at least one appropriately sized fire extinguisher. The equipment is also furnished with both manual and automatically actuated fire suppression system.

6.7 Escape plan

The Brucejack mine has two independent and separate accesses to surface – the West Zone portal and the conveyor ramp portal. Both ramps are primary fresh air intakes and act as the egress routes to surface.

In the event of a mine emergency, personnel are to report to surface or the nearest refuge chamber.

For personnel working in the VOK production areas, the route of escape is to the VOK ramp, the West Zone ramp, and out the West Zone portal. Level to level secondary egress is provided for in the VOK area with an escape way ladder system located in the fresh air raises connecting the levels. An alternate escape route is to surface via the conveyor ramp. The lower conveyor ramp has two access points; from the VOK ramp at 1290 Level and the West Zone ramp connection at the 1335 Level.

Escape route maps are to be posted in the refuge stations and in other conspicuous areas of the mine.

Figure 6-2 shows an overview of the mine escape routes and the location of the permanent refuge station. Also shown is the fresh air flow direction. The portable chambers will be relocated as required as the mining locations evolve over the life of mine.

Figure 6-2 Escape plan

Regulatory Baseline & Reference Documents

Regulatory Baseline
The following documents have been considered as both applicable and enforceable for the purposes of this Design Criteria

A. BC Building Code 2012 Edition
B. Health Safety and Reclamation Code for Mines in British Columbia 2008 Edition
C. BC Fire Code 2012 Edition
D. WorkSafe BC Part 22 Underground Workings
E. ULC S-524 M2006– Fire Alarm Installation Standard
F. CSA Standard CAN/CSA-M424.2-M90, Non-Rail-Bound Diesel-Powered Machines for Use in Non-Gassy Underground Mines
G. NFPA 10 - Fire Extinguishers
H. NFPA 13 – Fire Protection (Sprinklers)
I. NFPA 14 - Standpipes
J. NFPA 20 – Fire pumps

Non Enforceable Reference Documents
Other documents that are considered non enforceable but having applicability for good practice have also been considered for the purposes of this Design Criteria. These documents are:

A. NFPA 122 Standard for Fire Prevention and Control in Metal/Non Metal Mining – 2010 Edition
B. NFPA 2001 – Clean Agent Suppression
C. NFPA 15 – Transformer protection
D. NFPA 16 – Foam Protection
E. FM Standards – Where Applicable

General Document Structure

For each area or hazard underground at Brucejack, the following is described:

Key Factors – The underlying factors that lead to the developed design criteria

Identified Hazards – Elements within this building (or sub portion of a building) that constitute a risk to people, assets, or productivity.

Fire Alarm Coverage – Description of the extent to Fire Alarm coverage for this area.

Fire Suppression Coverage - Description of the extents of Standpipe, Sprinkler, Fire Extinguishers, Foam and Clean Agent for this area.

"ALL CONTENT HEREIN IS TO BE CONSIDERED INTELLECTUAL PROPERTY AND/OR TRADE SECRETS OF PRETIVM/TYCO AND IS TO BE UTILIZED FOR THE SUPPORT OF THE BRUCEJACK PROJECT. ANY OTHER USE IS PROHIBITED"

Brucejack Site – VOK Portal Bldg / Mine Underground Heater Bldg

1.1 Key Factors

- Occupancy type F3
- Non-combustible construction
- Critical egress point for underground
- Onsite Fire Department

1.2 Identified Hazards

- Flammable gas
- Surface air pollution (smoke)

1.3 Fire Alarm – Coverage

Provide a fire alarm control panel that directly communicates with site wide fire alarm network complete with audible/visual notification device coverage and manual pull stations at all exits. Pull stations in non-heated areas will be installed in Nema 4 enclosures. Smoke detection will be provided at the top of any enclosed stairwells. Sprinkler flow and tampers shall be monitored by the fire alarm system and the valve room shall be monitored for low temperature detection to alert of any risk of freezing.

High sensitivity smoke detection shall be provided on downstream side of underground air supply fan to provide protection against any smoke drawn from the surface.

Process Interface shutdowns will be provided in the event of Portal Building Fire to:

- Shutdown Portal Fan
- Shutdown Conveyor

In addition to the interlocks described above, additional High Sensitivity Smoke Detection points shall be installed at the Transfer Station and Crusher Station, see the Conveyor section for further detail on how these interlocks shall interact with the VOK Fan logic.

"ALL CONTENT HEREIN IS TO BE CONSIDERED INTELLECTUAL PROPERTY AND/OR TRADE SECRETS OF PRETIVM/TYCO AND IS TO BE UTILIZED FOR THE SUPPORT OF THE BRUCEJACK PROJECT. ANY OTHER USE IS PROHIBITED"

1.4 Standpipe, Sprinkler, Fire Extinguishers – Coverage

Standpipe and Fire Extinguisher coverage shall be provided throughout the VOK Portal building in accordance with BCBC 2012 and NFPA 14 (Standpipe) and NFPA 10 (Fire Extinguishers). Automatic sprinkler coverage will be provided for the conveyor pulley area. See additional pertinent details below:

- Class 1 standpipe system shall be installed in VOK PORTAL BUILDING to facilitate effective firefighting capabilities. The wet zone valve will be fed from the fire water 8" main (by others). Fire Hose Cabinets shall be located at exits and other locations where required due to overall distance considerations. Cabinets shall be placed at each platform level to facilitate firefighting of large equipment.
- Fire extinguishers shall be placed within the standpipe cabinets and throughout the building as required.

"ALL CONTENT HEREIN IS TO BE CONSIDERED INTELLECTUAL PROPERTY AND/OR TRADE SECRETS OF PRETIVM/TYCO AND IS TO BE UTILIZED FOR THE SUPPORT OF THE BRUCEJACK PROJECT. ANY OTHER USE IS PROHIBITED"

Brucejack Site – VOK Portal Electrical Rooms

2.1 Key Factors

- Occupancy type F3
- Non-combustible construction
- 2 Hour Fire Rating Separating Electrical Room from VOK Building
- Local Fire Department

2.2 Identified Hazards

- Electrical Equipment / Cabling (insulation)

2.3 Fire Alarm – Coverage

Provide air sampling based Vesda system that directly communicates with the fire alarm system. The system shall provide multiple levels of early detection (despite the high air flows anticipated in this room for cooling) to draw attention to an issue prior to evacuating the building or releasing any potential suppression system.

2.4 Standpipe, Sprinkler, Fire Extinguishers – Coverage

Sprinkler coverage is not recommended in this room as it can damage sensitive electrical equipment. The electrical room is to be separated from the VOK Building with a 2 Hour Fire Rating, allowing for compliance to BC Building code without providing sprinklers.

"ALL CONTENT HEREIN IS TO BE CONSIDERED INTELLECTUAL PROPERTY AND/OR TRADE SECRETS OF PRETIVM/TYCO AND IS TO BE UTILIZED FOR THE SUPPORT OF THE BRUCEJACK PROJECT. ANY OTHER USE IS PROHIBITED"

Underground – Conveyor Tunnels / Transfer Station

3.1 Key Factors

- Fire Retardant Belt (as required by HSRC)
- Local Fire Department

3.2 Identified Hazards

- Conveyor belt
- Electrical cables (insulation)
- Motors
- Bearings (friction source)

3.3 Fire Alarm – Coverage

Any sprinkler flow and tampers will be monitored with addressable inputs connected to the closest fire alarm panel. The underground transfer station and the conveyor area at/near the bottom of the crusher conveyor feed sprinkler devices shall be monitored by the substation or the underground crusher panels as appropriate.

Audible visuals shall be located near any areas of sprinkler coverage. In the event a flow of water is detected the fire alarm system shall shut down the conveyor(s), to limit the spread of fire and enhance the efficacy of the Red Line high flow fire extinguishers. In addition, high sensitivity smoke detection (Vesda) at the Transfer Station and at the Crusher will detect smoke produced by a conveyor belt fire and allow for the following interlock logic:

1) Fire Door closure direct from the Fire Alarm system by local addressable (Fire Alarm) relay
2) Integration (Modbus or similar) with the mine airflow system to slow the standard 5m/sec rate down to allow for maximum efficacy of the Red Line high flow fire extinguishers.
3) Integration (Modbus or similar) with the mine process control system to stop conveyer immediately.

These same Vesda systems, along with the additional Vesda unit in the Vok Building (just downstream of the supply fan) will be integrated with the VOK building mine airflow system to determine when the fire is likely coming from within the VOK building itself. Specifically:

A) First alarm (chronologically), and high values from the VOK Vesda plus second alarm (chronologically) and lower values from the Transfer Station and Crusher Vesda likely indicate a VOK fire (or VOK drawing smoke from another surface fire).
B) A reverse of the above where the first alarm and higher values come from either the Transfer Station or the Crusher likely indicate a conveyor fire where the VOK air supply Shall be maintained but at a slower rate than the standard 5m/s.

These process interlock conditions shall be discussed further with the owner/operator and refined prior to implementation however the base design is that fire alarm will control the doors directly where mine airflow and conveyor systems will be a case of fire alarm notifying those systems for final control.

See Images Overleaf:

"ALL CONTENT HEREIN IS TO BE CONSIDERED INTELLECTUAL PROPERTY AND/OR TRADE SECRETS OF PRETIVM/TYCO AND IS TO BE UTILIZED FOR THE SUPPORT OF THE BRUCEJACK PROJECT. ANY OTHER USE IS PROHIBITED"

3.4 Standpipe, Sprinkler, Fire Extinguishers – Coverage

Automatic sprinkler protection shall be provided for the conveyor tail and head pulleys, plus the transfer station. Detailed design shall be in accordance with the FM requirements detailed below.

4. Protect important production belt conveyors running in tunnels or passageways which are accessible for manual fire fighting with automatic sprinklers over drive motors, end pulleys, or other known or common friction or ignition points or sources. Extend sprinklers 50 ft (15 m) beyond in both directions and space at10 ft (3 m) intervals on lines. Design sprinkler activation to sound an alarm at a constantly attended location and shutdown the conveyor system..*

"ALL CONTENT HEREIN IS TO BE CONSIDERED INTELLECTUAL PROPERTY AND/OR TRADE SECRETS OF PRETIVM/TYCO AND IS TO BE UTILIZED FOR THE SUPPORT OF THE BRUCEJACK PROJECT. ANY OTHER USE IS PROHIBITED"

The entire conveyor system shall be provided with firefighting equipment in the form of high flow/extended discharge, cartridge operated Red Line type fire extinguishers. To maximize the efficacy of these extinguishers the high sensitivity smoke detection in the Vok Portal (downstream of supply fan), Transfer Station, and Crusher Station points shall be interlocked with the supply air as described in the preceding fire alarm section.

In addition, standpipe systems shall be installed at the Crusher Station, Transfer Station and VOK Portal building where pulleys create a greater source of friction and potential ignition.

"ALL CONTENT HEREIN IS TO BE CONSIDERED INTELLECTUAL PROPERTY AND/OR TRADE SECRETS OF PRETIVM/TYCO AND IS TO BE UTILIZED FOR THE SUPPORT OF THE BRUCEJACK PROJECT. ANY OTHER USE IS PROHIBITED"

Underground – Fuel Bay and Oil & Grease Storage

4.1 Key Factors

- Local (Surface) Fire Department Response

4.2 Identified Hazards

- Fuel Hazard & Ignition risk (vehicle)
- Restricted access for fire fighting

4.3 Fire Alarm – Coverage

Provide a fire alarm control panel connected to the underground/site wide fire alarm network. Pull stations and audible/visual coverage shall be provided throughout this area. Flammable fluid hazards shall be monitored with linear heat detection zones including supervision and control of the fire suppression system. A means to manually release each hazard both from within this area and outside of this area will be provided.

4.4 Standpipe, Sprinkler, Fire Extinguishers – Coverage

Provide an AFF foam fire suppression system for the entire fuel bay area up to the fire doors at either end of the bay. Containment shall be provided by sloping & grading in combination with an appropriately sized sump with an oil/water separator. The foam fire suppression system shall be automatically activated and also be equipped with manual activation points both within and outside of the fuel bay area.

Fire doors shall be interfaced with the fire detection/suppression system to close automatically in the event of fire. This interface means shall be by direct fire alarm relay.

See coverage image overleaf:

"ALL CONTENT HEREIN IS TO BE CONSIDERED INTELLECTUAL PROPERTY AND/OR TRADE SECRETS OF PRETIVM/TYCO AND IS TO BE UTILIZED FOR THE SUPPORT OF THE BRUCEJACK PROJECT. ANY OTHER USE IS PROHIBITED"

"ALL CONTENT HEREIN IS TO BE CONSIDERED INTELLECTUAL PROPERTY AND/OR TRADE SECRETS OF PRETIVM/TYCO AND IS TO BE UTILIZED FOR THE SUPPORT OF THE BRUCEJACK PROJECT. ANY OTHER USE IS PROHIBITED"

Underground – Refuge / Lunch Room

5.1 Key Factors

- Local Fire Department (Surface)
- Limited combustible load (limited storage)

5.2 Identified Hazards

- Class A materials
- Ignition sources, cooking equipment

5.3 Fire Alarm – Coverage

A fire alarm control panel that directly communicates with site wide fire alarm network c/w audible/visual coverage and manual pull stations at exit.

The fire alarm system shall also include smoke detection to provide early warning of an incipient fire. To accommodate the high ceiling a Vesda type air sampling system shall be utilized.

5.4 Standpipe, Sprinkler, Fire Extinguishers – Coverage

All fire extinguishers in the Underground – Refuge/Lunch Room will be spaced no further than 75 ft travel, they will be 20lb Stored Pressure 10A;120B;C Dry Chemical Extinguisher charged with ABC Powder.

"ALL CONTENT HEREIN IS TO BE CONSIDERED INTELLECTUAL PROPERTY AND/OR TRADE SECRETS OF PRETIVM/TYCO AND IS TO BE UTILIZED FOR THE SUPPORT OF THE BRUCEJACK PROJECT. ANY OTHER USE IS PROHIBITED"

Underground – Truck Shop/ Warehouse

6.1 Key Factors

- Non-combustible construction
- Local Fire Department (Surface)

6.2 Identified Hazards

- Vehicles
- Maintenance equipment
- Ignition sources (welding, grinding, etc.)

6.3 Fire Alarm – Coverage

Coverage considered under this Design Criteria is confined to the initial site build out which is through the two entry doors and up to the first cross cut. The image below shows the whole service garage area including the future cross cuts that will be created in future phases of truck shop expansion. Fire Alarm coverage is detailed as for the first cross cut only at this time.

Provide a fire alarm control panel connected to the underground/site wide fire alarm fiber network. Including Nema 4 enclosures for pulls stations, audible/visual notification devices and sprinkler supervision.

6.4 Standpipe, Sprinkler, Fire Extinguishers – Coverage

The area of coverage included in this design criteria is the same as that referred to in section 29.4 above (from the two entry doors, through to the first cross cut only).

Provide a wet type automatic sprinkler system based on FM Global Datasheet 7-12 Section 2.4.7

1. Where the ceiling of the bay above the mobile equipment is 60 feet (18 m) or less provide standard wet or dry pipe automatic sprinklers on a system designed to provide 0.45 gpm/ft2 (18 mm/min) over 5000 ft2 (12 mm/min over 460 m2) (wet pipe) or 8000 ft2 (740 m 2)(dry pipe) using 165°F (75°C) heads.

"ALL CONTENT HEREIN IS TO BE CONSIDERED INTELLECTUAL PROPERTY AND/OR TRADE SECRETS OF PRETIVM/TYCO AND IS TO BE UTILIZED FOR THE SUPPORT OF THE BRUCEJACK PROJECT. ANY OTHER USE IS PROHIBITED"

Underground – Crusher/Rock Breaker

7.1 Key Factors

- Non-combustible construction
- Local Fire Department (Surface_

7.2 Identified Hazards

- Lube Oil Unit
- Conveyor
- Electrical Equipment / Motors

7.3 Fire Alarm – Coverage

Provide a fire alarm control panel that directly communicates with site wide fire alarm network c/w audible/visual coverage for inside the control room and general Crusher area. Provide a pull station at the control room exit and at the area near the Crusher. Supervise sprinkler system for valve isolation and water flow. Interface to the process control system for shutdown upon fire system activation.

"ALL CONTENT HEREIN IS TO BE CONSIDERED INTELLECTUAL PROPERTY AND/OR TRADE SECRETS OF PRETIVM/TYCO AND IS TO BE UTILIZED FOR THE SUPPORT OF THE BRUCEJACK PROJECT. ANY OTHER USE IS PROHIBITED"

7.4 Standpipe, Sprinkler, Fire Extinguishers – Coverage

The Jaw Crusher discharge conveyor shall be protected with an automatic sprinkler system along it's complete length. The main conveyor pulley area shall also be protected with an automatic sprinkler system.

Hydraulic lube units shall be protected with an automatically activated wet chemical LVS type fire suppression system.

"ALL CONTENT HEREIN IS TO BE CONSIDERED INTELLECTUAL PROPERTY AND/OR TRADE SECRETS OF PRETIVM/TYCO AND IS TO BE UTILIZED FOR THE SUPPORT OF THE BRUCEJACK PROJECT. ANY OTHER USE IS PROHIBITED"

Underground – Substation

8.1 Key Factors

- Non-combustible construction
- Local Fire Department (Surface)
- Dry type transformers

8.2 Identified Hazards

- Restricted access (underground enclosure with one entry point)
- Cable/Insulation

8.3 Fire Alarm – Coverage

Provide a fire alarm control panel that directly communicates with site wide fire alarm network c/w audible/visual coverage and manual pull station at exit. Utilize an air sampling based Vesda type smoke detection system for effective sensing of smoke in the incipient stages in this high air change environment.

Monitor and control the Inergen Clean Agent system including the use of uniquely colored (blue) strobes located inside & outside of this room. These strobes shall indicate the system either has or will be released. Provide means to manually release the system, means to delay the release of the system (abort), monitor/control of suppression system and associated HVAC/damper controls to achieve the required pressure relief and agent containment parameters.

"ALL CONTENT HEREIN IS TO BE CONSIDERED INTELLECTUAL PROPERTY AND/OR TRADE SECRETS OF PRETIVM/TYCO AND IS TO BE UTILIZED FOR THE SUPPORT OF THE BRUCEJACK PROJECT. ANY OTHER USE IS PROHIBITED"

8.4 Standpipe, Sprinkler, Fire Extinguishers – Coverage

Provide an automatic Inergen Clean Agent/Inert Gas fire suppression system in a total flooding application for the main substation enclosure. This system shall comply with the HRSC requirements noted below and shall be rated and considered safe for occupied spaces.

3.10.2 Fire extinguishers which are capable of giving off or generating poisonous gas when operated shall not be allowed below ground and in confined spaces.

Portable fire extinguishers shall NOT be CO_2 type anywhere underground as they are considered a poisonous gas pursuant to HRSC *3.10.2* above. Instead Clean Guard type FE13-13lb (for ABC fires) extinguishers shall be provided in the main substation.

"ALL CONTENT HEREIN IS TO BE CONSIDERED INTELLECTUAL PROPERTY AND/OR TRADE SECRETS OF PRETIVM/TYCO AND IS TO BE UTILIZED FOR THE SUPPORT OF THE BRUCEJACK PROJECT. ANY OTHER USE IS PROHIBITED"

Paste Plant Booster Pumps

9.1 Key Factors

- Over 10L Flammable Fluid

9.2 Identified Hazards

- Hydraulic Unit

9.3 Fire Alarm – Coverage

Fire alarm coverage shall be provided to facilitate the automatic wet chemical fire suppression system. Refer to image below:

9.4 Standpipe, Sprinkler, Fire Extinguishers – Code Determination

Provide an automatic wet chemical LVS type fire suppresion system for the booster pumps, monitored and controlled by the fire alarm system.

Provide 40-B:C sized fire extinguishers at this location.

Brucejack Fire Simulations Report

Disclaimer

1) The effective date of this document is 21 August 2015.
2) This document has been prepared from mine ventilation system models adapted, from previous Feasibility Studies (prepared by others), by Ian M. Loomis and mine fire simulations conducted under his direction by Felipe Fernández and Alfonso Ovalle of AMEC International Ingenieria y Construcción Limitada (Amec Foster Wheeler).
3) The process and results were the topic of several meetings between Amec Foster Wheeler and Pretium personnel.
4) This material in this document has been reviewed by George Zazzi, Pretium, with comments as of the effective date incorporated into the text.
5) The basis and results presented in the report are based on the available knowledge of the proposed mine layout and mine ventilation system at the time that the study was undertaken (March 2015 through August 2015).
6) A connection beween the West Zone Access ramp and the VOK conveyor Decline is not included in this study since the modelers were not advised of this potential until after completion of the study. This has potential effects on an extension of Case1 that includes WZ and Case 3 – WZ Ramp Fire
7) The analysis are based on general and limited expectations of fire behavior as carried out by conventional mine ventilation simulations.
8) To my knowledge, no testing or field simulation had been done to verify the results.
9) The results are intended as guidance for the specific fire management cases addressed and are not, to my knowledge, backed by physical testing. Thus, this is not to be considered as a general response plan nor is this a design document.
10) I have not visited the mine site to verify the recommended/necessary fire detection systems and response relative to these recommendations.

Ian M. Loomis

1.0 INTRODUCTION

Using the ventilation models current at the time of the effort, several mine fire scenarios were considered and evaluated for the purpose of determining the likely areas/districts of the mine to be impacted by the particular cases and to assess/recommend courses of action to assist in mitigation of the spread of the smoke, heat, and other products of combustion. A key consideration in the recommendations, both as a response to a fire and as normal operating practice, is the maintenance of personnel normal egress and emergency escapeways. Since the Brucejack does not have a dedicated fresh air intake system (both intakes are used for haulage and equipment access), fires in the primary intakes warrant the consideration that immediate reversal of airflow, under the effect of the respective main fan, is a viable approach to quickly and efficiently clear the mine downstream of the fire. The approach of immediately reversing airflow is contradictory to generally established mining practice of obtaining full account of all personnel before making changes to the ventilation system and should, therefore, be taken with and under the advice of the mine's safety manager.

The spread of stench gas, as an alarm system, was analyzed for both zones at their respective period of initial stoping. The results indicate that, consistent with routine practice, the use of stench gas should be limited to use as secondary alarm system (this approach is within the mine operational plan) . The primary alarm should be through the mine communication system using radios, information display panels, light boards, etc. to ensure that as much information as possible can be sent to personnel working underground.

Conveyor belt and mobile equipment fires are considered here in cases where standard fire prevention and/fire control systems are assumed to have failed. Normal fire prevention and control methods within the Brucejack operational plan account for the use of a fire rated conveyor belt and the specification of on-board fire extinguishers on heavy mobile equipment.

The effects of several mine fire scenarios were considered as a part of this study. Overall, seven cases were simulated that represent six scenarios including: stench gas distribution for both VOK and WZ areas, VOK conveyor decline fire, WZ access decline fire, WZ ramp fire, VOK ramp fire, and a production level fire. As an outcome of these models, countermeasures and evacuation routes are also proposed.

1.1 Study Content

Two different stages of the mine were considered for the fire simulations: i) intial VOK-stoping and ii) initial WZ-stoping. The following scenarios were considered:

- Stench gas distribution

- VOK Conveyor Decline Conveyor Belt Fire
- WZ Access Decline Truck Fire
- WZ Ramp Truck Fire
- VOK Ramp Truck Fire
- Generic Production Level Equipment fire

Countermeasures and evacuation routes are considered and proposed for each of the fire scenarios.

1.2 Conclusions and Recommendations

The use of Stench Gas as an alarm system was analyzed for both stages considered. Certain recommendations for implementation are provided that may enhance the effectiveness and speed of response to this technique. It is recommended that the use of Stench Gas be limited to a secondary warning system. Potential alternatives and primary alarm systems are discussed in the stench gas section.

Table 1-1 lists the respective initial countermeasures and escape routes proposed based on the five fire scenarios considered. More detailed and advanced countermeasures are addressed in respective detail in following sections.

Table 1-1: Mine Fire Modelling and Recommended Countermeasures and Evacuation

Brucejack Project Fire Cases Simulated					
Case	Location	Stage	Fire Source	Countermeasures	Evacuation Route
1	VOK Conveyor Decline	Initial WZ-Stoping	Conveyor belt	Plan 1 Reverse the VOK Main Fan	Escapeway raises and WZ access decline
				Plan 2 Close the fire door to the production Ramp Fully open regulator/drive-through door at the exhaust of the jaw crusher conveyor area to VR-2 Exhaust regulators from other fixed facilities (crusher, truck loop) must be equipped with backflow preventers. Magazine fire doors closed VOK conveyor portal fan slowed to 50% of operating speed.	
2	WZ Access Decline	Initial WZ-Stoping	Truck	The WZ Portal main fan must be stopped. The access doors to the fixed facility must be closed. Open airlock(s) between the WZ and VOK Open Airlock at WZ portal	No clear escape route available from the VOK area, personnel must head to the closest refuge Escapeway raises are may not be suitable for use.
3	WZ Production Ramp	Initial WZ-Stoping	Truck	Maintain airlock(s) between WZ and VOK closed. Stop the WZ Main Fan Start WZ Main Fan in reverse rotation	
4	VOK Production Ramp	Initial VOK-Stoping	Truck	Plan1 - If the fire is in the upper or lower sections of the ramp, the ventilation system will operate normally.	Escapeway raises and WZ access decline If not able to reach the WZ access decline, personnel must head to the nearest refuge
				Plan 2 – Fire in the middle section of the ramp Reverse VOK Main Fan to clear crusher Close door at lower conveyor/production ramp Open door from transfer conveyor to VR-2 Airlock(s) between VOK and WZ remain closed.	
5	Production Level	Initial VOK-Stoping	LHD	Ventilation system will operate in normal configuration	

2.0 FIRE MODELING AND RESULTS

2.1 Scenario Analysis

For this study, two stench gas distribution and five fire scenarios were analyzed. As appropriate, these were considered at the stage of initial stoping in the VOK or the initial stoping in the WZ.

The layout of the mine at the beginning of stoping in the VOK is shown in Figure 2-1.

Figure 2-1: Initial VOK Stoping Stage

The layout of the mine at the beginning of stoping in the WZ is shown in Figure 2-2.

Figure 2-2: Initial WZ Stoping Stage

2.2 Stench Distribution Cases

As a component of a mine's alarm system, stench gas (typically either methyl- or ethyl-mercaptan) is used to alert personnel working underground of an emergency requiring evacuation. This gas is generally injected into the mine ventilation system at the intake portals, which at the Brucejack Mine include both the VOK Conveyor Decline Portal and the WZ Portal entrance.

The time based stench gas distribution through the mine was considered for both the initial stoping at the VOK and at the WZ by applying a "contaminant" source at the respective portals. A time-step model was then run to determine the overall effectiveness of the stench gas distribution and the time required to spread throughout the mine.

2.2.1 Initial VOK Stoping Stage

In a stench gas release alarm, the gas will be released at both portals, so that the gas is distributed to all of the existing mine facilities. The distribution at five minutes after the release is shown in Figure 2-3, which shows distribution to the fixed facilities, crusher, and a portion of the VOK production ramp.

Figure 2-3: Stench Gas Spread after Five Minutes, Initial VOK Stoping

Figure 2-4 shows the distribution at 10 minutes after the initial release. By this time, all of the active areas of the mine have been alerted; however, areas that are not under active production or development activities will not be reached by this time.

Figure 2-4: Stench Gas Spread after 10 minutes, Initial VOK Stoping

2.2.2 Initial WZ Stoping Stage

When stoping begins in the WZ, there will be two ventilation circuits that are separated by an airlock. The VOK Conveyor Decline Portal will provide the majority of the intake air to the VOK and the WZ Portal will provide air to the WZ. Figure 2-5 shows the estimated distribution of stench gas five minutes after the initial release. Under these conditions, the stench gas is just beginning to arrive at the mine fixed facilities, crusher, and production levels on the VOK side and is reaching the upper production levels in the WZ.

Figure 2-5: Stench Gas Spread after Five Minutes, Initial WZ Stoping

After 10 minutes, the stench gas is beginning to spread through the central production levels in the VOK and is beginning to reach the lower production levels at the WZ. This is shown in Figure 2-6.

Figure 2-6: Stench Gas Spread after 10 Minutes, Initial WZ Stoping

Analysis

The distribution of stench gas through the mine is limited by the mine ventilation system. It is, therefore, recommended for use only as a backup alarm system. An alarm system consisting of the Wi-Fi Radio application (already within the mine operational plan), information panels/light boards, and other schemes should be provided to more quickly spread information relating to a mine emergency.

These simulations show that there is limited distribution of the stench gas to the production and development headings 10 minutes after the initial gas release. It is, therefore, recommended that the Brucejack Mine consider adding stench gas release points deeper within the mine, such as at a major intersection of the ventilation systems (i.e., the intersection of the two main declines and the ramps to ensure that the stench gets to the ramps and in parallel intake raise) to more quickly affect an alert in the mine.

2.3 Mine Fire Cases

2.3.1 VOK Conveyor Decline Fire

The case of a fire on the conveyor belt in the conveyor decline was studied as the initial fire case, and a separate technical memo was prepared (#M90177-CD-00-MEM-003). The fuel for the fire was considered to be the conveyor belt of the upper conveyor. The effects of this fire scenario were considered for both the initial stoping at VOK and initial stoping at WZ.

Note that the mine operational plan calls for a fire rated belt to inhibit initiation or sustain combustion as associated with that rating.

Initial Stoping in VOK

Based on the results of ventilation modeling, the intake ventilation in this case consists of 177.5 m^3/s in the VOK Conveyor Decline Portal and 169 m^3/s from the WZ Access Portal. The starting point for this scenario is shown in Figure 2-7.

Figure 2-7: Main Ventilation System Flow at Initial VOK Stoping

In this scenario, it is assumed that: a conveyor belt fire starts at the lower end (transfer station) of the upper conveyor, the fuel load is limited to the one km long belt, the spread rate will be 1 m/min, and that the belt is empty. This is shown in Figure 2-8.

Figure 2-8: Fire and Fuel Source on the VOK Conveyor Decline

Without controls (unmitigated) the products of combustion (POCs) reach the crusher area, the production ramp and some production levels within five minutes (Figure 2-9).

Figure 2-9: Spread of POCs, Five Minutes after Fire Starts

By 15 minutes after the fire starts, the POCs completely inundate the crusher area and the lower portion of the active production zone (Figure 2-10). The escapeway raises are not impacted at this point, since they receive their intake directly from the WZ access (assuming that the airlock in the "dog-leg" drift is closed).

Figure 2-10: Conveyor Fire, Spread of POCs, 15 Minutes

These results suggest a couple of modifications: install a normally closed airlock in the "dog-leg" connection between the WZ access decline and the lower flight of the conveyor; execute a procedure to fully open the exhaust regulator between the jaw crusher discharge conveyor and VR-2. These are illustrated in Figure 2-11.

A viable alternative to the normally closed airlock in the "dog-leg" is the normally open fire activated door in the mine operational plan.

Figure 2-11: Recommended Modifications to the Ventilation System

Countermeasure implementation:

Plan 1 – Reverse VOK Conveyor Decline Main Fan

This approach consists of only reversing the VOK conveyor decline main fan. There is a timeline that needs to be considered:

- Response Time – This is the time between the fire starting, an alarm sounding and countermeasures being implemented. It is estimated that the minimum will be between three and five minutes given the systems for the detection of smoke, CO, and/or elevated temperatures.
- Fan stop – assuming that the main fan is equipped with a break, the time to de-energize and stop the forward rotation of the fan is estimated at two to three minutes.
- Fan start in reverse – once the forward rotation of the fan is stopped, it is estimated that it will take between one and two minutes to bring the fan back to full speed in the reverse direction. Once the fan is operating in reverse, it is assumed that the airflow efficiency is 50% of the forward case.

Thus, the minimum time to implement the air flow reversal scheme will be between 6 and 10 minutes.

The layout of this approach is shown in Figure 2-12.

Figure 2-12: Single Countermeasure Approach

Implementation:

The estimated conditions in the mine 10 minutes after the fire starts are shown in Figure 2-13. By this time, POCs have entered into the VOK production ramp and the crusher facilities area.

Figure 2-13: Conditions 10 Minutes after Fire Starts

Once the fan reversal is implemented, the POCs begin to be extracted from the mine through the VOK Conveyor Portal. This clears the production ramp and allows evacuation of personnel through the WZ access. This condition is shown in Figure 2-14.

During the airflow reversal, it is estimated that the air temperature through the fan will rise to approximately 46°C within the first hour. This is below the estimated temperature that could begin to cause damage to the fan (60–70°C dry bulb). This is predicted to provide at least one hour of operation of the fan in reverse in order to implement a general mine evacuation.

Figure 2-14: Effect of Reversing the VOK Conveyor Portal Fan, 20 Minutes after Fire Starts

Figure 2-15: Predicted Temperature Rise at the VOC Conveyor Main Fan

As an additional feature to the approach, use of a fire door between the tail of the lower conveyor and the VOK production ramp should be considered. This reduces the response time and decreases the quantity of POCs entering the production areas (Figure 2-16).

Figure 2-16: POC Spread after 10 Minutes, with Augmentation by Closing Fire Door

This approach, however, results in the VOK conveyor main fan entering a stalled operating condition placing the fan at risk of structural failure. If this approach is considered, reducing the fan speed to 50% should be considered.

Plan 2 – Combined Countermeasures

This plan considers the effect of reducing the forward speed of the conveyor decline main fan and diverting the conveyor decline airflow to VR-2. This involves the following requirements and sequence of events:

- Fire detection systems (CO, smoke, and thermal) must be installed along the entire conveyor system to ensure a rapid response to a fire.
- A fire door must be installed in the connection between the lower VOK conveyor decline to the production ramp. This door must be actuated in response to the fire detection systems along the conveyor system.

- The exhaust access door from the jaw crusher discharge conveyor towards VR-2 must have fail-open controller that opens the door (5 m by 5 m), so that all of the conveyor decline ventilation can be diverted to VR-2.
- Exhaust regulators from other fixed facilities (shop, crusher tip, and magazine) must close when the jaw crusher discharge conveyor regulator is opened. It is recommended that these regulators also be equipped with back-flow preventers to ensure that POCs are not force backwards to the fixed facilities. Note: back flow preventors at these locations are reported to be in the mine operational plan to above automatic controls on the regulators.
- The VOK Conveyor Portal main fan speed must be reduced to 50% in the forward direction.

These features are illustrated in Figure 2-17.

Figure 2-17: Countermeasures to Isolate the VOC Conveyor Decline

Implementation:

This approach considers that it will take approximately five minutes for the POCs to reach the lower portion of the production ramp and to reach the crusher area (Figure 2-18). This is the point in time that it is assumed these countermeasures can be implemented; completion of the changeover is assume to occur by 10 minutes.

Figure 2-18: Conveyor Fire Simulation, CO Spread after Five Minutes

Ten minutes after the fire starts, it is assumed that the countermeasures are fully implemented. The production ramp area is cleared by exhausting the POCs through VR-1 and VR-3. The POCs within the VOC conveyor decline are directed through the jaw crusher discharge regulator to VR-2 (Figure 2-19).

Figure 2-19: Alternate Countermeasure System, POC Spread at 10 Minutes

Effects of This Approach

During normal operation, the development ventilation/escapeway raises receive fresh air from the WZ access decline; if that source is maintained clear, then personnel can use the raises to bypass the POCs in the production ramp. In order to maintain that separation of intake airflow, it is recommended that the isolation airlock in the "dog-leg" connection be maintained normally closed. This is predicted to provide sufficient isolation that the WZ access decline can serve as the primary egress (Figure 2-20).

For normal operations purposes, a remotely activated, single, normally-open door may be preferred in the"dog-leg" rather than the normally closed airlock. This can be considered a viable alternative with the door closing as part of the fire response sequence.

Figure 2-20: Evacuation Route

Based on these simulations, the recommended response to this scenario is:

- Close the fire door to the production ramp.
- If normally-open door is used in the "dog-leg" - close this fire door.
- Fully open the regulator/drive-through door at the exhaust of the jaw crusher discharge conveyor area to VR-2.
- The exhaust regulators from the other fixed facilities (crusher, truck loop) must be equipped with backflow preventers. Magazine fire doors closed.
- The VOK conveyor portal fan must be slowed down to 50% of its rated full speed.

- Proper maintenance and calibration of the fire detection system along the conveyor belt is critical.

This approach does not materially impact the flow of air that would be perceived by the underground workers, which should help avoid confusion during the evacuation process.

Initial Stoping WZ

The general layout of the mine at the time of initial stoping in the WZ is shown in Figure 2-21. The airlock shown in the WZ access decline creates an effective barrier to the spread of the fire POCs to the WZ production area.

Figure 2-21: Conveyor Belt Fire Scenario, Initial WZ Stoping

Figure 2-22 illustrates the spread of the fire POCs five minutes after initiation by which time the POCs have reached the VOK production ramp and the crusher areas. By 10 minutes, the fire POCs have inundated the crusher area and are spreading through the VOK production ramp (Figure 2-23).

Figure 2-22: Conveyor Belt Fire, POC Spread after Five Minutes, Initial WZ Stoping

Figure 2-23: Conveyor Belt Fire, POC Spread after 10 Minutes, Initial WZ Stoping

As a means to control the POC spread through the mine, a procedure to reverse the VOK main fan was recommended for the VOK only case above. To cause a faster response when the WZ in is production in the mine for diverting the POCs from the conveyor fire, it is also recommended to implement the following countermeasures: close the fire door that connects the conveyor decline to the production ramp; stop the VOK Conveyor Portal main fan; open the airlock in the WZ exploration access decline. The fire door can be closed immediately after the fire has been detected to prevent the spread of POCs into the VOK production ramp (this would occur approximately five minutes after the fire's initiation). At the same time, the fire door is closed the VOK Conveyor Portal main fan must be stopped.

A secure evacuation route is predicted by opening the WZ exploration access decline airlock, so that the WZ Portal fan is providing forced airflow through the VOK (Figure 2-24).

Figure 2-24: Conveyor Belt Fire, POC Spread after 10 Minutes with Countermeasures

Figure 2-25: Flow Chart Case 1 Response

2.3.2 Truck Fire in the WZ Access Decline

This fire case assumes that a haulage truck is burning in the WZ exploration/access decline between the WZ and the VOK. The initial status is that the mine is operating under normal conditions at the time of the fire (Figure 2-26).

Figure 2-26: WZ Access Decline, fire source location, initial VOK stoping

Because the WZ access decline is a major intake drift, the POCs spread quickly and inundate the VOK production levels (Figure 2-27). Because the access decline intake air flows directly to the development ventilation intake raises, the POCS will quickly spread that development headings. Furthermore, since the POCs will also enter to the ramp system, both the primary (decline) and secondary (intake raises) will be impacted. Since both the primary and secondary escapeways may be affected in this scenario, personnel should have the option to seek refuge on their production levels.

Figure 2-27: WZ Access Decline Fire, POC Spread after Five Minutes, Initial VOK Stoping

As in the conveyor fire case, a reversal of flow through the WZ Portal fan may limit the spread of POCs through the underground. However, due to the time required for the reversal to be initiated and implemented, it is still expected that POCs would reach production levels (Figure 2-28).

Figure 2-28: WZ Access Decline Fire, POC Spread after 10 Minutes, Initial VOK Stoping

The effect of the reversal on the distribution of POCs, five minutes after the reversal is implemented (Figure 2-29).

Figure 2-29: WZ Access Decline Fire, POC Spread after 15 Minutes with Fan Reversal

Steps that can be considered for controlling or limiting the impact of a fire in the WZ access/exploration decline include: installing a normally open fire door in the decline at the intersection to the VOK production ramps, implementation of a procedure to stop the WZ Portal main fan, and providing fire rated doors at the entrances to the fixed facility areas (already provided for). These are indicated and shown in Figure 2-30.

Figure 2-30: WZ Access Decline Fire, POC Spread 10 Minutes after Fire Door Activation

Figure 2-31: Flow Chart of Case 2 Response

2.3.3 Truck Fire in WZ Production Ramp

In this scenario, at the beginning of stoping in the WZ, a haul truck fire is considered in the upper section of the WZ production ramp. In this case, by 10 minutes after the fire starts, the POCs have inundated several upper levels and have reached the surface through the WZ exhaust raise. Additionally, due to the source of air into the development ventilation/escapeway raise, that raise is also affected by the spread of POCs (Figure 2-32).

Figure 2-32: WZ Ramp fire, POC spread after 10 minutes, Initial WZ Stoping

By 15 minutes after the fire starts, the POCs have reached to lowest level of the WZ and in the escapeway raise (Figure 2-33). Under these conditions, personnel would need to rely on refuges on each production level.

Figure 2-33: WZ Ramp Fire, POC Spread after 15 Minutes, Initial WZ Stoping

Since it is not practical to locate a fire control door on the production ramp or in the production access drifts, an option to reverse the main fan needs to be considered to keep the levels clear of POCs. The case of implementing a reversal of the main fan is shown in Figure 2-34, which is taken 15 minutes after the fire begins and 5 minutes after the reversal of the main fan is completed.

Figure 2-34: WZ Ramp Fire, POC Spread after 15 Minutes with Main Fan Reversal

Figure 2-35: Flow Chart of Case 3 Response

2.3.4 Truck Fire in VOK Production Ramp

Due to the variety of conditions and airflow patterns associated with the VOK production ramp, a truck fire is considered at three locations along the ramp: upper portion of the ramp, lower portion of the ramp, and in the middle portion of the ramp. Each of these cases is discussed separately.

Fire in the Upper VOK Production Ramp

Figure 2-36 shows the event of a truck fire in the upper portion of the VOK production ramp. In this event, the POCs move across an active production level and then are exhausted through an exhaust raise. The escapeway raise system remains clear in this scenario and can be used by personnel to by-pass the fire in the ramp.

Figure 2-36: Upper VOK Ramp Fire, POC Spread after 10 Minutes

Fire in the Lower VOK Production Ramp

Figure 2-37 shows the event of a truck fire in the lower portion of the VOK production ramp. The POCs move across an active production level to the exhaust raises. The escapeway raise system remains clear in this scenario and can be used by personnel to by-pass the fire in the ramp.

Figure 2-37: Lower WZ Ramp Fire, POC Spread after 10 Minutes

Fire in the Middle Portion of the VOK Ramp

Figure 2-38 shows the event of a truck fire in the middle portion of the VOK production ramp. In this scenario, the crusher/truck loop will be impacted by the spreading POCs. Within five minutes of the fire starting, the crusher/truck loop and active production levels are being impacted by the fire.

Figure 2-38: Middle WZ Ramp Fire, POC Spread after Five Minutes

By 10 minutes after the start of the fire, the crusher/truck loop and the nearest active production level are inundated as shown in Figure 2-39. The analysis indicates that reversing the airflow through the conveyor portal main fan is a prudent action to exhaust contaminants from the mine. The predicted conditions 20 minutes after the start of the fire and 10 minutes after reversing the main fan are shown in Figure 2-40. Within the production area, the escapeway raises are predicted to remain clear allowing personnel to escape via the WZ access; however, personnel in the crusher area may need to use the nearest refuge chamber/station.

Figure 2-39: Middle WZ Ramp Fire, POC Spread after 10 Minutes

Figure 2-40: Middle WZ Ramp Fire, POC Spread after 20 Minutes with Fan Reversal

Figure 2-41: Flow Chart of Case 4 Response

2.3.5 Production Level Fire

The event of a Loader (LHD) fire on typical production level is shown in Figure 2-42. In this scenario, it is predicted that the POCs will be carried across the level to the main exhaust raise system. The effect of the fire on airflow across the level is shown in Figure 2-43. This illustrates that although there is some throttling effect due to the fire, the airflow remains towards the exhaust and does not reverse towards the production ramp.

Figure 2-42: VOK Production Level, LHD Fire, POC Spread after Five Minutes

Chapter 10 Appendix

Appendix 10-1: ENV Declarations Forms

Ministry of Environment and Climate Change Strategy

Conflict of Interest Disclosure Statement

A qualified professional [1] providing services to either the Ministry of Environment and Climate Change Strategy ("ministry"), or to a regulated person for the purpose of obtaining an authorization from the ministry, or pursuant to a requirement imposed under the *Environmental Management Act,* the *Integrated Pest Management Act* or the *Park Act* has a real or perceived conflict of interest when the qualified professional, or their relatives, close associates or personal friends have a financial or other interest in the outcome of the work being performed.

A real or perceived conflict of interest occurs when a qualified professional has

a) an ownership interest in the regulated person's business;

b) an opportunity to influence a decision that leads to financial benefits from the regulated person or their business other than a standard fee for service (e.g. bonuses, stock options, other profit sharing arrangements);

c) a personal or professional interest in a specific outcome;

d) the promise of a long term or ongoing business relationship with the regulated person, that is contingent upon a specific outcome of work;

e) a spouse or other family member who will benefit from a specific outcome; or

f) any other interest that could be perceived as a threat to the independence or objectivity of the qualified professional in performing a duty or function.

Qualified professionals who work under ministry legislation must take care in the conduct of their work that potential conflicts of interest within their control are avoided or mitigated. Precise rules in conflict of interest are not possible and professionals must rely on guidance of their professional associations, their common sense, conscience and sense of personal integrity.

Declaration

I Alison Shaw, as a member of Engineers and Geoscientists BC declare

Select one of the following:

☒ Absence from conflict of interest

Other than the standard fee I will receive for my professional services, I have no financial or other interest in the outcome of this Brucejack Mine 4950 tpd Joint Amendments Application. I further declare that should a conflict of interest arise in the future during the course of this work, I will fully disclose the circumstances in writing and without delay to Todd Adamsson, erring on the side of caution.

[1]*Qualified Professional, in relation to a duty or function under ministry legislation, means an individual who*

a) is registered in British Columbia with a professional association, is acting under that organization's code of ethics, and is subject to disciplinary action by that association, and

b) *through suitable education, experience, accreditation and knowledge, may reasonably be relied on to provide advice within his or her area of expertise, which area of expertise is applicable to the duty or function.*

Ministry of Environment and Climate Change Strategy

Declaration of Competency

The Ministry of Environment and Climate Change Strategy relies on the work, advice, recommendations and in some cases decision making of qualified professionals[1], under government's professional reliance regime. With this comes an assumption that professionals who undertake work in relation to ministry legislation, regulations and codes of practice have the knowledge, experience and objectivity necessary to fulfill this role.

1. Name of Qualified Professional Alison Shaw

   Title Senior Geochemist

2. Are you a registered member of a professional association in B.C.? ☑ Yes ☐ No

   Name of Association: Engineers and Geoscientists BC Registration # 47412

3. Brief description of professional services:

   Authored Appendix 5-3 (Brucejack Mine: 4950 tpd Water Quality Model Report) and contributed to sections 2.1, 2.3, 2.4, 5 and 7.

This declaration of competency is collected under section 26(c) of the *Freedom of Information and Protection of Privacy Act* for the purposes of increasing government transparency and ensuring professional ethics and accountability. By signing and submitting this statement you consent to its publication and its disclosure outside of Canada. This consent is valid from the date submitted and cannot be revoked. If you have any questions about the collection, use or disclosure of your personal information please contact the Ministry of Environment and Climate Change Strategy Headquarters Office at 1-800-663-7867.

Declaration

I am a qualified professional with the knowledge, skills and experience to provide expert information, advice and/or recommendations in relation to the specific work described above.

[1] *Qualified Professional, in relation to a duty or function under ministry legislation, means an individual who*

a) is registered in British Columbia with a professional association, is acting under that organization's code of ethics, and is subject to disciplinary action by that association, and

b) *through suitable education, experience, accreditation and knowledge, may reasonably be relied on to provide advice within his or her area of expertise, which area of expertise is applicable to the duty or function.*

Ministry of Environment and Climate Change Strategy

Conflict of Interest Disclosure Statement

A qualified professional [1] providing services to either the Ministry of Environment and Climate Change Strategy ("ministry"), or to a regulated person for the purpose of obtaining an authorization from the ministry, or pursuant to a requirement imposed under the *Environmental Management Act,* the *Integrated Pest Management Act* or the *Park Act* has a real or perceived conflict of interest when the qualified professional, or their relatives, close associates or personal friends have a financial or other interest in the outcome of the work being performed.

A real or perceived conflict of interest occurs when a qualified professional has

a) an ownership interest in the regulated person's business;

b) an opportunity to influence a decision that leads to financial benefits from the regulated person or their business other than a standard fee for service (e.g. bonuses, stock options, other profit sharing arrangements);

c) a personal or professional interest in a specific outcome;

d) the promise of a long term or ongoing business relationship with the regulated person, that is contingent upon a specific outcome of work;

e) a spouse or other family member who will benefit from a specific outcome; or

f) any other interest that could be perceived as a threat to the independence or objectivity of the qualified professional in performing a duty or function.

Qualified professionals who work under ministry legislation must take care in the conduct of their work that potential conflicts of interest within their control are avoided or mitigated. Precise rules in conflict of interest are not possible and professionals must rely on guidance of their professional associations, their common sense, conscience and sense of personal integrity.

Declaration

I **Brett DeHay-Turner**, as a member of **EGBC** declare

Select one of the following:

☐ Absence from conflict of interest

Other than the standard fee I will receive for my professional services, I have no financial or other interest in the outcome of this _____.

I further declare that should a conflict of interest arise in the future during the course of this work, I will fully disclose the circumstances in writing and without delay to _____, erring on the side of caution.

Ministry of Environment and Climate Change Strategy

☒ Real or perceived conflict of interest

Description and nature of conflict(s):

I am employed by Newcrest Mining Ltd.

I will maintain my objectivity, conducting my work in accordance with my Code of Ethics and standards of practice.

In addition, I will take the following steps to mitigate the real or perceived conflict(s) I have disclosed, to ensure the public interest remains paramount:

Continue to uphold EGBC's Code of Ethics that is required under the Professional Governance Act, S.B.C. 2018, p. 47

Further, I acknowledge that this disclosure may be interpreted as a threat to my independence and will be considered by the statutory decision maker accordingly.

This conflict of interest disclosure statement is collected under section 26(c) of the *Freedom of Information and Protection of Privacy Act* for the purposes of increasing government transparency and ensuring professional ethics and accountability. Ministry of Environment and Climate Change Strategy

Conflict of Interest Disclosure Statement

A qualified professional [1] providing services to either the Ministry of Environment and Climate Change Strategy ("ministry"), or to a regulated person for the purpose of obtaining an authorization from the ministry, or pursuant to a requirement imposed under the *Environmental Management Act,* the *Integrated Pest Management Act* or the *Park Act* has a real or perceived conflict of interest when the qualified professional, or their relatives, close associates or personal friends have a financial or other interest in the outcome of the work being performed.

A real or perceived conflict of interest occurs when a qualified professional has

a) an ownership interest in the regulated person's business;

b) an opportunity to influence a decision that leads to financial benefits from the regulated person or their business other than a standard fee for service (e.g. bonuses, stock options, other profit sharing arrangements);

c) a personal or professional interest in a specific outcome;

d) the promise of a long term or ongoing business relationship with the regulated person, that is contingent upon a specific outcome of work;

e) a spouse or other family member who will benefit from a specific outcome; or

f) any other interest that could be perceived as a threat to the independence or objectivity of the qualified professional in performing a duty or function.

Qualified professionals who work under ministry legislation must take care in the conduct of their work that potential conflicts of interest within their control are avoided or mitigated. Precise rules in conflict of interest are not possible and professionals must rely on guidance of their professional associations, their common sense, conscience and sense of personal integrity.

[1] *Qualified Professional, in relation to a duty or function under ministry legislation, means an individual who*

a) is registered in British Columbia with a professional association, is acting under that organization's code of ethics, and is subject to disciplinary action by that association, and

b) *through suitable education, experience, accreditation and knowledge, may reasonably be relied on to provide advice within his or her area of expertise, which area of expertise is applicable to the duty or function.*

Ministry of Environment and Climate Change Strategy

Conflict of Interest Disclosure Statement

A qualified professional [1] providing services to either the Ministry of Environment and Climate Change Strategy ("ministry"), or to a regulated person for the purpose of obtaining an authorization from the ministry, or pursuant to a requirement imposed under the *Environmental Management Act,* the *Integrated Pest Management Act* or the *Park Act* has a real or perceived conflict of interest when the qualified professional, or their relatives, close associates or personal friends have a financial or other interest in the outcome of the work being performed.

A real or perceived conflict of interest occurs when a qualified professional has

a) an ownership interest in the regulated person's business;

b) an opportunity to influence a decision that leads to financial benefits from the regulated person or their business other than a standard fee for service (e.g. bonuses, stock options, other profit sharing arrangements);

c) a personal or professional interest in a specific outcome;

d) the promise of a long term or ongoing business relationship with the regulated person, that is contingent upon a specific outcome of work;

e) a spouse or other family member who will benefit from a specific outcome; or

f) any other interest that could be perceived as a threat to the independence or objectivity of the qualified professional in performing a duty or function.

Qualified professionals who work under ministry legislation must take care in the conduct of their work that potential conflicts of interest within their control are avoided or mitigated. Precise rules in conflict of interest are not possible and professionals must rely on guidance of their professional associations, their common sense, conscience and sense of personal integrity.

Declaration

I Sylvia Van Zalingen (Print First and Last Name), as a member of BC Institute of Agrologists (Print Name of Professional Association) declare

Select one of the following:

☐ Absence from conflict of interest

Other than the standard fee I will receive for my professional services, I have no financial or other interest in the outcome of this 4950 tpd Joint M-243/PE-107835 Amendments Application (application/project/contract/etc) I further declare that should a conflict of interest arise in the future during the course of this work, I will fully disclose the circumstances in writing and without delay to Todd Adamsson (Insert Ministry Contact Name), erring on the side of caution.

Ministry of Environment and Climate Change Strategy

☒ Real or perceived conflict of interest

Description and nature of conflict(s):
I am an employee of the applicant and permittee - Pretium Resources Inc., and my position/role is to manage the preparation of permit applications and permittee components of review processes for same, with the objective of obtaining permits required for Brucejack Mine operations.

I will maintain my objectivity, conducting my work in accordance with my Code of Ethics and standards of practice.

In addition, I will take the following steps to mitigate the real or perceived conflict(s) I have disclosed, to ensure the public interest remains paramount:
This form is included/disclosed in the 4950 tpd Joint Application. I will continue to abide by the BC Insitute of Agrologists Bylaw Sections 93 to 98 for standards of conduct and competence, including adherence to the Code of Ethics. The reclamation liability cost estimate for the Brucejack Mine has been prepared by WSP.
Further, I acknowledge that this disclosure may be interpreted as a threat to my independence and will be considered by the statutory decision maker accordingly.

This conflict of interest disclosure statement is collected under section 26(c) of the *Freedom of Information and Protection of Privacy Act* for the purposes of increasing government transparency and ensuring professional ethics and accountability. By signing and submitting this statement you consent to its publication and its disclosure outside of Canada. This consent is valid from the date submitted and cannot be revoked. If you have any questions about the collection, use or disclosure of your personal information please contact the Ministry of Environment and Climate Change Strategy Headquarters Office at 1-800-663-7867.
